levels, due to the advance on all acetate products.

General and Special Chemicals

Alums—Important producers and dealers are quoting 3½c, per lb. for the ammonia lump in quantity lots. Sales of the potash alum are recorded at 3½c. per lb.

Acetate of Lime—Producers have announced another advance and the present market is being held around $3 per 100 lb. in bags. The new price is said to be due primarily to increased costs of production. Demand is quite active.

Acetone—A new advance due to increased costs of production is reported and a more pronounced demand is evident. The new figure ranges around 12½c. per lb.

Arsenic—Manufacturers are now quoting as high as 10½c. per lb. for prime white powdered material on spot. Supplies are very limited for immediate delivery and demand continues quite active. Futures are quoted at 10@10½c. per lb.

Barium Carbonate—Spot material is obtainable at $75 per ton. Several large tonnage sales were reported at this figure. The general range is around $75@$80 per ton.

Bleaching Powder—Leading producers quote 2c. per lb., f.o.b. works for carload quantities and report an active demand. Shipments over the remainder of the year are held at the same price.

Caustic Soda—The export demand is moderate at $3.45@$3.50 per 100 lb., f.a.s., standard brands. Dealers report a very good movement for domestic consumption at $3.75@$4 for 100 lb., ex-store New York. A heavy demand is reported on contract, with producers quoting $2.50 per 100 lb., basis 60 per cent f.o.b. works.

Formaldehyde—Makers announced an advance to 13½c. per lb., f.o.b. works in carload lots. On account of the advance in methanol, producing costs have increased and this is maintaining a strong market for the product.

Sal Ammoniac—Imported white granular is somewhat easier on spot at 6½c. per lb. The gray variety is very scarce and some sellers are asking up to 8½c. per lb. The general tone is fair.

Methanol—Producers have sharply advanced prices and the market was exceedingly active, with production in most instances well sold ahead. Quotations for the 95 per cent were heard around 90@92c. per gal. The 97 per cent was quoted at 92@94c. per gal. Denatured and ethyl alcohol remained unchanged.

Coal-Tar Products

The general condition of the market maintained a steady tone in most of the crude products and intermediates. Business continued moderately active, with no depressing tendencies noted. Inquiries from consumers are reaching the market in fair amount and indications point to a gradual increase in the volume of business. Phenol still continued to be the feature of the market, with supplies exceedingly scarce. H acid was advanced by several leading sellers. Orthonitrotoluene was also quoted higher, with the demand quite active.

Aniline Oil—An active demand for this material is holding the market steady at 16c. per lb. Several interests recorded some fair-sized tonnage transactions at this level. Smaller lots were quoted at 17c. per pound.

Alpha-naphthylamine—Producers are placing a fair business at 29c. per lb. and report a very steady market. The general range is around 29@30c. per pound.

H Acid—Producers quote much higher prices for this product and while resale lots can be had at slight concessions, the general tone is much firmer at 85@90c. per pound.

Phenol—A very strong demand continues to feature this market. Offerings are very limited and available material is being held at high levels. Several transactions were recorded at 26c. per pound.

The Iron and Steel Market

PITTSBURGH, Oct. 20, 1922.

Fundamental conditions in the steel market have continued to soften. Buying of steel products has dropped to small proportions, the turnover in the past week having easily been the lightest in any week thus far this year. There have been no distinct declines in steel prices, but there is, generally speaking, an easier tone. This is seen definitely in the decreases that have occurred in the premiums that have to be paid to get early deliveries of sheets and plates. In bars the delivery premium is perhaps a shade less. In tin plates and wire products there have been no delivery premiums.

Steel Production

The prospect is that the mills with the leaner order books will soon have occasion to curtail production and that they will do this in preference to cutting prices in an effort to develop business. They will have some business, booked at prices recently prevailing, to protect. The Steel Corporation is well filled with business and will probably continue to run well. Two years ago a somewhat similar condition obtained. The corporation actually increased its operations slightly, fuel and labor becoming more plentiful, while the independents as a whole reached a low operating rate. In each case the corporation's better filled order book is to be ascribed to the following of a conservative policy in prices.

Car supplies at steel mills have not improved materially and little progress has been made in moving the steel recently piled. Shipping conditions have not grown worse, and there is less complaint among buyers.

Steel Prices

In general, steel products are steady at basis prices, 2c. being the basis for bars, shapes and plates, while plain wire is 2.45c. and wire nails $2.70. Prompt plates now rarely command more than 2.15c., while a fortnight ago 2.25c. was not uncommon and a month ago small lots were bringing as high as 2.50c. Prompt bars rarely bring 2.25c. now, but 2.15c. is not uncommon. In sheets the 3.35c. basis of the Steel Corporation is nominal in that the corporation is sold out until it opens its order books for first quarter. Among independents there have been prices of 3.50c., 3.60c. and 3.75c., according to the delivery the particular mill could make, but 3.75c. practically disappeared recently, and 3.60c. is now less common than 3.50c. as a settling price.

A curious incident is furnished by the National Tube Co. advancing its prices on welded tubular goods about $4 a ton under date of Oct. 19. No change in prices had been expected, particularly when prices of other steel commodities are not in stiffening mood. Pipe advances, however, had been very conservative, and order books are better filled than is the case with some other steel products. The new basing discount is 66 per cent on merchant steel pipe. On last year's readjustment a minimum of 71 per cent was reached. The net advance from the low point, five points, figures out a trifle less than $9 a net ton.

Coke

Connellsville furnace coke, which had ruled stiff at $12 for several weeks, began softening about 10 days ago and then proceeded to break, offers of standard grade having been made yesterday and today at $8 without finding takers. Production has continued to increase and when prices began to soften consumers became disposed to postpone purchases, so that from the demand and offerings standpoint the market has been under double pressure. With coal at $3 the coke equivalent would be about $5.75, so that there is room for more decline. Coke has sometimes sold at less than its coal equivalent.

Pig Iron

Pig iron, which was in very poor request throughout the period of exceptionally high prices when nearly all the merchant furnaces were idle, has been softening with the increasing production. The combination of consumers now receiving deliveries on old purchases and of prices declining naturally does not stimulate demand. Asking prices are down to $33 for bessemer, $30 for basic and $32 for foundry, f.o.b. valley furnaces, and there may be little buying of real tonnages until prices have developed their new level, in keeping with coke at a reasonable price in relation to its cost of production. Wages at the union coal mines are the same as before the strike, while in the Connellsville region wages are up fully 40 per cent. In January and February coke sold at about $3 and pig iron at $18 to $19, both coke and pig iron producers asserting these prices were below actual cost of production.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

TARRANT CITY—The National Cast Iron Pipe Co. has preliminary plans in progress for the erection of a new foundry. A special system for cast-iron pipe production will be installed. It is expected to commence work early in the coming year.

MOBILE—The Patterson Oil Co., Conception and Virginia Aves., is reported to be planning for the immediate rebuilding of the portion of its plant recently destroyed by fire with loss estimated at about $60,000, including equipment.

TUSCALOOSA—Fire, Oct. 3, destroyed Foundry No. 3, at the local plant of the Central Foundry Co., with loss estimated at about $65,000. It is planned to rebuild at a later date. Headquarters of the company are at 41 East 42nd St., New York.

Arkansas

PINE BLUFF—The Jefferson County Cotton Oil Co. is installing new equipment at its plant for considerable increase in capacity. I. L. Hathaway is general manager.

FORT SMITH—The Athletic Mining & Smelting Co. has plans under way for enlargements in its plant, to include the installation of about 1,600 new retorts, arranged in two major blocks, and a new kiln at the zinc smelter. It is expected to commence work early in 1923.

FORT SMITH—The Zenor Bottle Co. has plans under consideration for the installation of new equipment at its plant. The company was recently incorporated with a capital of $50,000, to take over a local plant. C. P. Zenor is president, and James B. McDonough, vice-president.

CAMDEN—The Bradstreet Oil Co. is planning for enlargements in its storage and distributing plant. A number of new 55,000-bbl. storage tanks, with auxiliary equipment, will be installed.

Colorado

DENVER—The Producers' & Refiners' Corp., California Bldg., has plans in progress for the construction of a new oil-refining plant in the vicinity of Fort Steele, Wyo. It is also proposed to build a similar plant at Omaha, Neb. New pipe lines, pumping plants, etc., will be installed.

Florida

JACKSONVILLE—The Tidewater Glass Mfg. Co. has awarded a general contract to Frank Richardson, Jacksonville, for the erection of a new plant on local site to cost about $150,000, including machinery. Work will be placed under way at once.

California

LOS ANGELES—The Amalgamated Talc Co. has plans nearing completion for the construction of a new 1-story plant, 40x160 ft., on East 1st St. Milling machinery, cleaning apparatus and other equipment will be installed. A. Godfrey Bailey, Junior Orpheum Bldg., is architect.

OLEUM—Fire, Oct. 1, destroyed a portion of the oil storage and distributing plant of the Union Oil Co., Los Angeles, in the San Pablo Bay district, with loss estimated at about $250,000, including tanks, stock, etc. It is planned to rebuild.

LOS ANGELES—The W. P. Fuller Paint Co., Los Angeles, is taking bids through Hudson & Munsell, 444 Douglas Bldg., architects, for the erection of a new 1-story plant at Barranca St. and Ave. 22, estimated to cost approximately $40,000.

LOS ANGELES—The Shell Oil Co. of California, San Francisco, is planning for enlargements in its plant in the harbor section, to include a new refinery in the vicinity of Wilmington, for handling the output of the Signal Hill oil wells. The work is estimated to cost close to $1,000,000, including machinery.

LOS ANGELES—The Kay-Brunner Co. has awarded a contract to the Austin Co., Pacific Electric Bldg., for the erection of a 1-story foundry, 56x152 ft., on Frederick St., near Cypress Ave.

Georgia

AUGUSTA—The plant and property of the Planters' Cotton Oil Co. have been acquired by new interests, headed by John Aspewgren. The new owners will operate the mill and have tentative plans under consideration for extensions and improvements.

Illinois

OLMSTEAD—The Sinclair Refining Co., 111 West Washington St., Chicago, has completed plans and will commence work early in December, for a new 1-story mill, 70x115 ft., here, for the production of fullers earth.

Indiana

EVANSVILLE—The Evansville Enameling Co. has plans in progress for the erection of a new 1-story plant addition, 50x85 ft., sawtooth roof type.

Kentucky

RUSSELLVILLE—The Independence Nitro Co. has plans under way for the erection of a new local plant for the production of nitroglycerine and kindred products.

Louisiana

GRETNA—The Gulf Refining Co., New Orleans, has plans in progress for the installation of a new storage and distributing plant on local site.

Maryland

CUMBERLAND—The Better Brick Co., recently organized, has acquired a tract of property on the Allegheny Grove district, and plans for the construction of a new plant for the manufacture of hollow tile blocks, concrete brick and kindred products. The works will consist of a number of buildings. Theodore Smith is general manager.

BALTIMORE—The Argol Sulphide Co. has acquired a tract of land, totaling about 2 acres, on Curtis Ave., Curtis Bay, for a consideration of about $10,000, and is said to be planning to use the site for a new plant. It has been held heretofore by the Standard Wholesale Phosphate Co.

BALTIMORE—The American Oil Co., American Bldg., has purchased a portion of the Smith's shipyard property at Curtis Bay, consisting of about 10 acres, and has tentative plans under consideration for a new storage, handling and distributing plant, estimated to cost close to $500,000, including machinery.

BALTIMORE—The Crown Oil & Wax Co., 22 South Eighth St. is planning for the rebuilding of the portion of its plant destroyed by fire, Oct. 10. An official estimate of loss has not been announced.

BALTIMORE—The Bartlett-Hayward Co., Scott and McHenry Sts., will build a new 1-story foundry, 200x262 ft., at its iron and steel works. The erection contract has been let to the Whiting Turner Construction Co., 427 East Lombard St. Howard Bruce is president.

Massachusetts

CLINTON—The Clinton Gas Light Co., Pleasant St., has plans in progress for the construction of a new artificial gas plant. Walter W. Russell, 77 Franklin St., Boston, is engineer.

Michigan

DETROIT—The Detroit Foundry Co., Grand Boulevard and Orleans St., has leased the former foundry of the American Blower Co., in the vicinity of its plant, with building totaling about 50,000 sq.ft. of floor space, on 2-acre site, and will use the property for immediate extensions. The privilege of purchase at a later date has also been secured.

Missouri

CAPE GIRARDEAU—The McCracken Pip Co., Sioux City, Ia., has tentative plan under consideration for the erection of new plant on local site, for the manufactur of concrete sewer pipe and other concret pipe products. It is estimated to cost abou $30,000. J. W. McCracken is president.

MALDEN—The Roberts Cotton Oil Co. i considering the rebuilding of the portion o its plant, recently destroyed by fire, wit loss estimated at about $25,000.

Montana

NEIHART—The American Zinc & Lead Co has awarded a contract to the Stearn Rogers Mfg. Co., Denver, Colo., for the con struction of a new concentrating mill, esti mated to cost in excess of $500,000. Worl will be placed under way at an early date

Nebraska

OMAHA—The Standard Chemical Co. ha taken possession of its new plant at 42n St. and Leavenworth Ave. and removed it former works on Harney St. to this location Considerable increased capacity will be pro vided.

New Jersey

GLOUCESTER—The City Council will soor award a contract for the installation of a new filtration plant at the municipal waterworks.

NEWARK—The W. H. Hughes Co., Inc. 507 West 35th St., New York, manufacturer of enamels, paints, lacquers, etc., has leased the entire building at 164 Coit St., Irvington, heretofore held by the Pierce, Butler, Pierce Mfg. Co., New York, manufacturer of boilers, etc. The new owners will take immediate possession for a branch plant.

New York

NEW YORK—The American Smelting & Refining Co., 120 Broadway, has plans in progress for extensions and improvements in its plants in Colorado to cost in excess of $5,000,000, including buildings and machinery.

Ohio

PORT CLINTON—The American Gypsum Co. has plans in preparation for the erection of a 1- and 2-story addition to its local plant, 65x70 ft., to be used for the manufacture of wall plaster and kindred products.

CLEVELAND—The Otis Steel Co., Jennings Ave., is having revised plans prepared for the erection of its proposed new plant addition, estimated to cost close to $3,000,000. It is proposed to construct the mills with force employed directly by the company.

DAYTON—The Lowe Brothers Co., 452 East 3rd St., has construction under way on a new addition to its paint manufacturing plant. John M. Lowe is president.

Oklahoma

HOLDENVILLE—The C. R. Cordell Oil Co. has plans under way for the construction of a new compounding and blending plant for the production of lubricating oils.

CUSHING—The Shaffer Refining Co. will soon commence the erection of an addition to its local plant, comprising a new four-unit cracking mill, estimated to cost approximately $500,000. It is proposed to have the new plant ready for service in the spring of the coming year.

OKLAHOMA CITY—The Mineral Bank Mining Co., 507 Baltimore Bldg., has inquiries out for a new ball mill, to be used in connection with its gold concentrating and amalgamating plant.

Pennsylvania

PHILADELPHIA—The Independence Mfg. Co., Aramingo St. and Wheatsheaf Lane, manufacturer of greases, tallow, etc., has filed plans for the erection of a new 1-story building at Coral St. and Wheatsheaf Lane.

PHILADELPHIA—The Philadelphia Cut Glass Co., Redfield St., near Baltimore Ave., has awarded a contract to the Farrell Roth Construction Co., 122 Diamond St., for the erection of a new 1-story plant, 80x90 ft.

PUNXSUTAWNEY—The Elk Run Window Glass Co. is planning for the rebuilding of the portion of its plant destroyed by fire, Oct. 3, with loss of about $12,000.

PHILADELPHIA—The Precision Grinding Wheel Co., 8301 Torresdale Ave., manufacturer of abrasive materials, will commence the immediate erection of a new 1-story plant addition.

PHILADELPHIA—Fire, Oct. 5, destroyed a large portion of the plant of H. Swoboda & Son, Inc., Bodine St., manufacturer of leather products, with loss estimated in excess of $150,000, including equipment.

LOCK HAVEN—The American Aniline Products Co. has plans under way for the construction of a new 3-story factory, 45x90 ft., to replace a fire loss of a number of months ago. It will be equipped for grinding and other service. Another structure of approximately like size will also be built.

Tennessee

ROCKWOOD—The Roane Iron Co. has tentative plans under consideration for the rebuilding of the portion of its local plant, recently destroyed by fire with loss estimated in excess of $100,000, including equipment.

Texas

HOUSTON—The Houston Terminal Refining Co., recently organized with a capital of $500,000, has plans in progress for the enlargement of its local oil refinery, comprising the former plant of Hoffman & Turnblow, lately acquired. The purchase includes 28 acres of land on the Houston Ship Canal, a portion of which will be used for the proposed expansion.

DALLAS—The Southwestern Dehydration Co., 409 Andrews Bldg., recently organized with a capital of $125,000, has acquired a local 4-story building, 75x125 ft., and will commence the immediate installation of equipment for a new plant.

CORSICANA—Fire, Oct. 3, destroyed a portion of the plant of the Southland Cotton Oil Co., with loss estimated at about $80,000. Plans for rebuilding are under consideration. C. C. Roberts is local manager.

BRAZORIA—The Union Sulphur Co., Sulphur, La., has acquired a tract totaling about 210 acres of land at Brazoria, as a site for the erection of a new mining, refining and terminal plant, estimated to cost in excess of $4,000,000, including machinery.

Virginia

BIG STONE GAP—The W. W. Taylor & Son Co. is planning for the establishment of a local plant for the manufacture of bricks and kindred burned clay products. Inquiries are being made for various equipments for installation.

Washington

EVERETT—The Whitman County Iron Co. has negotiations under way with the local Chamber of Commerce for a new site for the erection of a steel mill, with blast furnace and other structures. The initial capacity of the plant will be about 50 tons daily. E. G. Hammer is vice-president in charge.

VANCOUVER—The local Chamber of Commerce has negotiations under way with a company, whose name will be announced at a later date, for a suitable site for the erection of a new mill for molybdenum steel production. John O. Bender, Los Angeles, Calif., is interested in the project.

West Virginia

PARKERSBURG—The General Porcelain Co. has commenced the erection of its proposed plant—1-story plant addition, 65x225 ft., estimated to cost about $25,000.

Industrial Developments

RUBBER—The Republic Rubber Co. has resumed operations in the tire-making department at its Youngstown, O., plant, following a shut-down for close to 2 years past. The inner tube and mechanical rubber goods departments at this factory are running full, with normal working force. The tire-manufacturing department at the Canton O., plant of the company is operating under a capacity schedule.

The Mason Tire & Rubber Co., Akron, O., has adopted a capacity operating schedule and expects to remain on this basis throughout the winter.

The Goodrich Tire & Rubber Co., Akron, O., is running on a production basis of about 20,000 tires a day, with full-time working force.

METALS—The Federal Steel Foundry Co., Chester, Pa., has resumed operations at its steel foundries, following an extended curtailment.

The Calumet & Hecla Co., Calumet, Mich., is running full at its local smelting plant, and has recently advanced the wage scale about 11 per cent, affecting practically all classes of labor at the mills.

The Jennings Brothers' Co., Bridgeport, Conn., producer of gold and bronze products, is increasing production at its plant, and a number of additions are being made in the working force. Business is about 50 per cent better than at this same time a year ago.

The Unifed States Cast Iron Pipe & Foundry Co., Burlington, N. J., is operating at full capacity at its local plant, with employment of regular working force.

The Utah Consolidated Mining Co., Tooele, Utah, is operating at capacity at its new milling plant, and is also running full at its copper smelter. A large working force is being employed.

The American Brass Co., Waterbury, Conn., is advancing production to a point in excess of pre-war production at its different plants. All of the mills in the Naugatuck Valley are running close to capacity, while western plants will soon be on a similar basis. Additional workers have been added.

The Davis-Daly Co., Butte, Mont., is running on one full-time shift at its local properties, with present output totaling about 500 tons of copper ore per day.

The Park-Utah Mining Co., Salt Lake City, Utah, is advancing production at its copper properties from 160 to 250 tons. An increased working force is being employed.

The Ray Consolidated Copper Co., Ray, Ariz., is increasing production at its mills. The wage scale has been advanced recently 10 per cent.

The American Smelting & Refining Co., New York, is advancing operations at its Mexico mills, and will make substantial additions in the working force.

IRON AND STEEL—The Delaware River Steel Co., Chester, Pa., is arranging for the early resumption of operations at its plant after a shut-down since December, 1920. The plant normally gives employment to about 350 men, and initial production will be increased gradually to this full working quota.

There are now 27 blast furnaces in operation in the Mahoning Valley district, Ohio, which equals the highest record of production for the year, established several months ago before the recent curtailment.

The Foley Steel Mills, Slatington, Pa., have resumed operations after a curtailment of a number of months.

The Carnegie Steel Co. has blown in blast furnace No. 1 at its Sharon, Pa., works, following a shut-down for about 8 weeks. Two out of three stacks are now in operation at this plant.

The Illinois Steel Co., Chicago, Ill., has 15 blast furnaces in service at its plant and has advanced steel production to about 70 per cent of mill capacity.

The Bethlehem Steel Co. has blown in another blast furnace at its Steelton, Pa., plant, making three units now in service here.

The Brier Hill Steel Co., Youngstown, O., has established a new high record for steel ingot production at its local 12-in. furnace, with output for September totaling 68,197 ingot tons, compared with previous high figures in October, 1920, of 67,640 tons. The new production total is said to be a world's record.

The American Steel & Wire Co. has resumed operations at its hot mills at Sharon, Pa.

The Altoona Iron Co., Altoona, Pa., has resumed production at its local plant with a 60 per cent operating force. This will be increased gradually to normal. The plant is said to have sufficient orders on hand to insure continuous operations for a number of months.

The Inland Steel Co., Chicago, Ill., has all three blast furnaces in service at its plant and has placed the steel mills on a basis of about 65 per cent of capacity.

The American Sheet & Tin Plate Co. has started up all remaining hot mills at its Farrell, Pa., works, totaling 30, bringing production in this department to capacity for the first time in more than 2 years. Extensive additions will be made in the working force.

CERAMIC—The Jackson Vitrified China Co., Falls Creek, Pa., has granted the demand of employees for a 7 per cent wage advance, affecting about 100 workers. The men have returned to work after a brief strike.

A total of seven general ware plants at Trenton, N. J., are now inactive, owing to the strike of pottery operatives for increased wages. These are the two plants of the Greenwood Pottery Co., International Pottery Co., Cook Pottery Co., Mercer Pottery, the Lamberton Works of the Maddock Pottery Co., and the Unger Pottery. It is estimated that 2,000 workers are idle.

The Mt. Clemens Pottery Co., Mt. Clemens, Mich., has granted the demand of employees for a 7 per cent wage increase, and operations have been resumed at the pottery.

The Southern Potteries Co., Erwin, Tenn., has met the demand of employees for a 7 per cent wage advance, and production has been resumed at full capacity.

MISCELLANEOUS—The Hollow Ware & Enameling Co., Lancaster, Pa., is running full at its local plant, giving employment to more than 200 workers. A wage advance of 5 per cent for molders and laborers has recently been placed into effect.

The Montana Refining Co., Billings, Mont., has completed enlargements at its local oil refinery, providing a capacity close to double the previous output. The entire mill will be placed in service at an early date.

The Southwestern Graphite Co. has resumed operations at its works at Burnett, Tex., following a considerable curtailment.

Following a shut-down since Aug. 9 for necessary curtailment and repairs, the Interstate Glass Co. has resumed operations at its plant at Kane, Pa., giving employment to about 300 men.

The International Products Co., New York, manufacturer of tanning materials, is operating its quebracho plant in Paraguay at full capacity, on a basis of 25,000 tons per annum. This is an increase from 17,000 tons, produced in 1921, and 8,527 tons in 1920.

New Companies

THE UNION CHEMICAL CO., Burlington, N. J., has been incorporated with a capital of $50,000, to manufacture chemicals and chemical byproducts. The incorporators are Joseph Harrison, Harry M. Barg and Warren R. Rahn, all of Burlington. The last noted represents the company.

THE (N-G-R) ENERGY CO., 730 North Franklin St., Chicago, Ill., has been incorporated with a capital of $5,000, to manufacture washing compounds and kindred specialties. The incorporators are A. E. and R. E. Anderson, and Frank T. Tolkuehn.

THE GILL LEATHER CO., Salem, Mass., has been incorporated with a capital of $50,000, to manufacture leather products. John Gill, Wisteria St., Salem, Mass., is president and treasurer, and represents the company.

THE S. JACK HAINES CORP., New York, N. Y., care of J. J. Ryan, 355 East 149th St., representative, has been incorporated with a capital of $10,000, to manufacture shellacs, varnishes, etc. The incorporators are S. Jack Haines and M. Spitzer.

THE BOWIE COTTON OIL CO., Bowie, Tex., has been incorporated with a capital of $150,000, to manufacture cotton oil products. The incorporators are H. O. Bannon and R. C. Feagin, both of Bowie.

THE CLINCHFIELD MICA CORP., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws with capital of $1,000,000, to manufacture mica products.

THE NOVATONE CO., Brooklyn, N. Y., care of J. H. Garmesy, 51 Chambers St., New York, N. Y., representative, has been incorporated with a capital of $5,000, to manufacture paints, dyes and affiliated products. The incorporators are L. and M. Ornstein, and J. Randolph.

THE MID-CITY FOUNDRY CORP., 1901 Rockwell St., Chicago, Ill., has been incorporated with a capital of $15,000, to manufacture iron, steel and other metal castings. The incorporators are Frank Cedarwell, Innart Dahlberg and Carl J. Berg.

THE ARRENDALE OIL CO., El Dorado, Ark., has been incorporated with a capital of $100,000, to manufacture petroleum products. The incorporators are Samuel Arrendale, and W. L. Breyfogle, both of El Dorado; and W. M. Hall, Kansas City, Mo.

THE HIGH-GRADE LEMON POLISHING CO., 144 Parker St., Newark, N. J., has filed notice of organization to manufacture polishing oils. The company is headed by Michael Monetti.

THE TARRANTINE MFG. CO., INC., Bangor, Me., has been incorporated with a capital of $96,000, to manufacture soap products. Hugo H. Hanson is president; Samuel F. Chalfin, treasurer; and Charles D. Bart-

bett, clerk, all of Bangor. The last noted represents the company.

THE RISHER FIRE BRICK CO., Room 842, 10 South La Salle St., Chicago, Ill., has been incorporated with a capital of $40,000, to manufacture firebrick, tile and other refractory products. The incorporators are Howard E. and E. B. Risher, and Herbert O. Engstrom.

THE PORTABLE REFINERY CO., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws with capital of $500,000, to manufacture petroleum products.

THE ALBION MECHANICAL RUBBER MFG. CO., Richmond, S. I., N. Y., care of B. O. Eadie, St. George, S. I., representative, has been incorporated with a capital of $5,000, to manufacture mechanical rubber products. The incorporators are J. E., E. M. and K. V. Dubois.

THE BIRMINGHAM, LITTLE & PROSSER CO., Kansas City, Mo., has been incorporated with a capital of $60,000, to manufacture paper products. The incorporators are John Birmingham, E. H. Becker and Con J. Murphy, all of Kansas City.

THE SLENDAFORM CORP., New York, N. Y., care of Harry S. Hechheimer, 1540 Broadway, representative, has been incorporated with a capital of $20,000, to manufacture chemicals and affiliated products. The incorporators are W. N. Hechheimer and G. J. Lloyd.

THE LLOYD-BRECKENRIDGE GREASE CO., 608 South Dearborn St., Chicago, Ill., has been incorporated with a capital of $25,000, to manufacture lubricating oils, greases, etc. The incorporators are W. H. Breckenridge, C. B. Lloyd, and R. S. Robbins.

THE TWO STATES LIME CO., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws with capital of $1,500,000, to manufacture lime products.

THE REED-MACLAURY RUBBER CO., St. Louis, Mo., has been incorporated with a capital of $10,000, to manufactue rubber specialties. The incorporators are A. A. and B. E. Reed, and J. D. Maclaury, all of St. Louis.

THE NEWTON OIL CO., Newton, Mass., has been incorporated with a capital of $200,000, to manufacture oil products. Daniel J. Sullivan, 37 Glenwood Ave., Newton Centre, Mass., is president and treasurer.

THE KO-KONDEL CO., Houston, Tex., has been incorporated with a capital of $14,000, to manufacture chemical specialties, insecticides, etc. The incorporators are T. E., J. W. and H. F. Harrington, all of Houston.

THE ALBANY STEEL & BRASS CORP., 716 West Madison St., Chicago, Ill., has been incorporated with a capital of 100 shares of stock, no par value, to manufacture steel, brass, bronze and other metal products. The incorporators are J. Kendall, Herbert Green and G. Mitchell.

THE UNITED STATES & MEXICAN OIL CO., Richmond, Va., has been incorporated with a capital of $15,000,000, to manufacture petroleum products. The incorporators are Cyrus W. Beale and Guy B. Hazlegrove, both of Richmond, who will act as president and secretary, respectively.

THE NIAGARA CHEMICAL CO., Middleport, N. Y., care of G. F. Thompson, Middleport, representative, has been incorporated with a capital of $500,000, to manufacture chemicals and chemical byproducts. The incorporators are E. Knapp and C. P. H. Schoellkopf.

THE LINCOLN STEEL CO., Woodhaven, L. I., N. Y., care of the United States Corporation Co., 65 Cedar St., New York, N. Y., representative, has been incorporated under Delaware laws with capital of $1,250,000, to manufacture steel products. The incorporators are Charles A. Follet, Woodhaven; George E. Follet, Richmond Hill, L. I.; and George W. Wheeler, East Orange, N. J.

THE UNITED STATES GLASS CORP., Pittsburgh, Pa., has been incorporated with a nominal capital of $5,000, to manufacture glass products. The incorporators are W. W. McAdams, B. D. Booker and Frank J. Holan, 747 Union Arcade, Pittsburgh. The last noted is treasurer and represents the company.

THE KEN-O-TEX OIL CO., Muskogee, Okla., has been incorporated with a capital of $25,000, to manufacture petroleum products. The incorporators are W. J. Chapman, L. R. Chambers and J. W. Patterson.

THE H TYREE CHEMICAL CO., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., has been incorporated under Delaware laws with a capital of $200,000, to manufacture chemicals and chemical byproducts.

New Publications

THE REHEATING OF COMPRESSED AIR. By C. R. Richards and J. N. Vedder. Bull. 130, published by the Engineering Experiment Station, University of Illinois, Urbana, Ill.

THE PRODUCTION OF NITRIC OXIDES AND OZONE BY HIGH-VOLTAGE ELECTRIC DISCHARGES. By Karl B. McEachron and R. H. George. Bull. 9, Engineering Experiment Station, Purdue University, Lafayette, Ind.

BOOKS

WOMEN IN CHEMISTRY: A STUDY OF PROFESSIONAL OPPORTUNITIES. Studies in Occupations, No. 4. The Bureau of Vocational Information, New York City. Here the student girl who is looking forward to chemistry as a life pursuit will find assembled an invaluable accumulation of information bearing on the problems in which she is most likely to be interested. This volume, as Dr. Herty quite truthfully points out in his letter of introduction, is "a comprehensive, conservative description of existing conditions, interspersed with sage advice as to the difficulties to be encountered, and with sound philosophy as to the benefits derived from devotion to a science whose goal is service to humanity." The text is divided into four parts. The first is a brief chapter on chemistry as a vocation, in which most stress is laid on the importance of chemistry in modern life and the need for adequately trained chemists. This is followed by a detailed analysis of positions in chemistry. In it are reviewed the opportunities offered by educational institutions, medical laboratories and hospitals, analytical and research laboratories of industry, of governmental and state institutions, and by several other related fields, such as library work and journalism. The third part of the book is devoted to training—both graduate and undergraduate. The text is concluded with a résumé of such important considerations as physical and mental requirements, salaries, means of securing positions, etc. An appendix contains much useful information on colleges and universities in which women may receive training in chemistry, prizes and grants available for research, fellowships and graduate scholarships open to women, scientific and technical publications and the national scientific societies for chemists.

BENN BROTHERS, London, published during September the third volume of H. H. Broughton's series on Electrical Handling of Materials, entitled "Electric Cranes." This volume, to which the two already published are introductory, deals in the most comprehensive manner with every kind of crane and crane mechanism. There are 300 illustrations and 65 tables. Another publication is "Recent Progress in Rubber Chemistry and Technology," by Dr. Philip Schidrowitz, also issued by Benn Brothers, which gives the results of research carried cut during the last few years. This company also announces a new series of full-length monographs, each of which will be devoted to some specialized parts of the broad field of gas and fuel, three of which will be ready this fall. Of these the first, "The Administration and Finance of Gas Undertakings, With Special Reference to the Gas Regulation Act, 1920," by George Evetts, consulting engineer, discusses the procedure necessary when applying for special acts of Parliament, the features of private bills, provisional orders, and so forth. A considerable amount of attention is given to financial features, the sliding scale, capital and revenue and the accounts of gas undertakings. The volume, in fact, is designed in such a way as to prove useful not only to technical gas officials but to directors, secretaries and accountants. In the second of these volumes, "Gasworks Recorders," the author, Dr. Leonard Levy, in addition to pointing out the innumerable uses to which recorders may profitably be put, so describes the construction and practical working of these instruments that all those who have to deal with them should have no difficulty in allocating and attending to defects on the spot. Almost every known form of recorder is dealt with, and there are 200 illustrations. Finally, "Modern Gasworks Chemistry," by Geoffrey Weyman, D.Sc., F.I.C., chief chemist to the Newcastle & Gateshead Gas Co., has primarily been written so as to form a companion volume to Meade's "Modern Gasworks Practice" and Hole's "Distribution of Gas." The two last-named volumes have now for some years provided for the requirements of the gasworks engineer and the distribution engineer respectively, but the equally important chemical phase of the science of gas making has been very inadequately provided for. Dr. Weyman has included in his volume every chemical test and process which is likely to be met with in even the largest gasworks.

Manufacturers' Catalogs

THE QUIGLEY FUEL SYSTEMS, INC., New York, calls attention to Bulletin A, just issued, giving a condensed description of the Quigley powdered coal system and appliances. The layout of a typical coal-milling plant is shown and the method of fuel distribution and control briefly described.

THE MERRIMAC CHEMICAL CO., Boston, Mass., has issued a pamphlet listing its products. This company is a manufacturer of chemicals for tanneries, paper mills, steel and wire works, textile mills, dye and chemical works, celluloid, smokeless powder and fertilizer manufacturers, artificial ice and refrigerating plants, foundries, brass finishers, engravers, etc.

THE L. R. CHRISTIE CO., Pittsburgh, Pa., has issued a catalog illustrating and describing its driers, calciners and coolers.

THE PENNSYLVANIA PUMP & COMPRESSOR CO., Easton, Pa., in a new 16-page bulletin, No. 202, describes the company's line of double-suction single-stage centrifugal pumps, containing useful engineering data.

THE BUFFALO FOUNDRY & MACHINE CO., Buffalo, N. Y., has issued an attractive catalog on vacuum drying, evaporation and other processes and the principal types of apparatus employed in modern industry, together with a brief description of "Buflovak" and "Buflokast" apparatus.

THE METALS COATING CO. OF AMERICA, Philadelphia, Pa., has issued an illustrated pamphlet describing the adaptability of the Schoop metal-coating process to commercial requirements, in a form of interest to industrial users.

AUTOMATIC & ELECTRIC FURNACES, LTD., 281 Gray's Inn Road, London, W. C. 1, England, calls attention to its new catalog dealing with Wild-Barfield automatic electric hardening equipments. Particular attention is given to the problems of heat-treatment and their solution by the use of electricity.

THE NASH ENGINEERING CO., South Norwalk, Conn., has issued Bulletin 25, on "The Jennings Hytor Vacuum Heating Pump Size M, Electric Motor Driven."

HERMAN A. HOLZ of New York has issued a pamphlet on "The Dommer Gas Calorimeter," which is a self-contained apparatus for the accurate and convenient determination of the heating value of gases.

Coming Meetings and Events

AMERICAN CHEMICAL SOCIETY will hold its spring meeting April 3 to 7, 1923, at New Haven, Conn.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its winter meeting at Richmond, Va., Dec. 7 to 9.

INTERNATIONAL CHAMBER OF COMMERCE will hold its second general meeting in Rome, Italy, March 19-26, 1923.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, 52 East 41st St., New York City Nov. 10—American Chemical Society (in charge), Society of Chemical Industry, American Electrochemical Society, Société de Chimie Industrielle, joint meeting. Nov. 17—American Electrochemical Society, regular meeting. Dec. 1—Society of Chemical Industry, regular meeting. Dec. 8—American Chemical Society, regular meeting. Jan. 5—American Chemical Society, regular meeting. Jan. 12—Society of Chemical Industry, Perkin Medal. Feb. 9—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting. March 9—American Chemical Society, Nichols Medal. March 23—Society of Chemical Industry, regular meeting. April 20—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting. May 4—American Chemical Society, regular meeting. May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting, May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.

Fixing Wages and Standards Of Living by Statute

IT WILL NOT be difficult for reasonable men to follow the logical mental processes of the Railroad Labor Board in reaching the conclusion that "the living wage" theory is untenable. The reader will recall the demand made on the board by A. C. WHARTON, labor member, to establish a "living wage" for railroad workers regardless of wages paid for similar work in other industries. He wanted to disregard all economic laws and considerations and determine a wage that would enable a family of five to live on an arbitrary standard.

It is much to the credit of the Labor Board that it has declined to yield to the demand for any such artificial method of fixing wages. Statutory determination of a standard of living and arbitrary setting of wages for a group of men without regard to conditions under which similar groups are working are fallacious ideas that cannot find acceptance. Standards of living result largely from personal aspirations, and wages must be determined on a basis of service with due regard for relative values. Standards of living are improving in this country, but, as the Labor Board wisely remarks, the movement must be gradual and "cannot be consummated in the twinkling of an eye by artificial expedients."

Enlightened Labor Policy

WITHIN the last week two stories have reached us which tell a whole volume of stories. A young chemical engineer in charge of a manufacturing unit wrote: "We are having all kinds of trouble with labor. Every morning brings a long line of colored gentlemen with employment cards to be made out and an equally long line of men getting their time. It's got so that you ease up to a kindly ace of spades and ask him if he would mind rolling a few ounces. He will usually say, Yes, he would mind!"

With that experience fresh in our minds we asked another man, a plant manager, whether he had labor troubles. "Why, no!" he replied. "We haven't had any for years!" Then it developed that this company had realized that its location was disagreeable and that in order to hold its men it would have to make the work and the living conditions attractive. This the company has done in so far as possible and its labor turnover is less than 5 per cent!

How this has been accomplished is an interesting story which some day may be told. In any case the sooner industrial men realize that satisfied labor is an asset and move in that direction the better it will be for them.

The best example of what can be done is that of the Philadelphia Rapid Transit Co. A few years ago the company was bankrupt. Today it is healthy. The one difference is that the loyalty of the employees has been enlisted. Today they realize that their interests and those of the company are identical. A wise executive has seen to it that this fundamental principle has been adhered to. This principle must be steadfastly and sincerely followed, otherwise the distrust of the worker will persist. While other companies fight strikes, the employees of the Philadelphia Rapid Transit Co. voluntarily reduce their own wages.

Is an enlightened labor policy worth while?

Packing Industry Adopts Research Program

EDITORIAL reference was made in our issue of June 7 to the research and educational program for the packing industry outlined by THOMAS E. WILSON as the development plan for the Institute of American Meat Packers. At the seventeenth annual meeting of the Institute held recently in Chicago, the plan was adopted at the close of a most interesting session in which Dean RALPH G. HEILMAN of the Northwestern University School of Commerce demonstrated the value of research and education to an industry. The specific benefits to the packing industry were discussed by such competent critics as OSCAR G. MAYER, ARTHUR LOWENSTEIN, W. D. RICHARDSON, L. D. H. WELD, ARTHUR CUSHMAN, M. D. HARDING and J. C. DOLD.

As a working program, the report of the Institute plan commission was also adopted. This recommends raising by individual volunteer subscription the sum of $50,000 a year for three years to be spent on educational and research activities. For the first year, recommendations include: the appointment of a director of research to be responsible, with adequate assistance, for the entire scientific work of the Institute; to enable the committee on practical research to handle all matters dealing with practical packing house operation, the service of a competent secretary will be required; as a start in educational work, a series of lectures designed primarily to give men engaged in the packing business a general survey of the entire industry and of company organization and operation will be given by well-known authorities in the industry. The appointment of a man technically familiar with the problems of industrial education is also recommended so that he may survey the educational possibilities and requirements of the industry.

Thus an immediate start will be made in the field of scientific research, practical research and education. It has wisely been thought best to proceed along unpretentious lines at first so that the growth may be natural and not forced. The packing industry is to be commended for its determination to support the plans laid by its forward-looking leaders. The development will be watched with a great deal of interest by all branches of the chemical and allied industries.

Renewed Demand for An International Economic Conference

IN EXPRESSING his desire for an international conference on economic and business matters, Judge GARY is only voicing the feelings of the business and industrial leaders of the country. Sentiment in favor of such a conference was very strong last spring, immediately following the Disarmament Conference in Washington. At that time the U. S. Chamber of Commerce made a special effort to get the Administration in Washington to take the leadership in calling such a conference, feeling that the apparent success of the Disarmament Conference augured well for a similar international gathering to deal with economic and industrial matters. The Administration, however, felt it undesirable either to invite an economic conference at Washington or to participate in one in Europe. Nevertheless many will still agree with Judge GARY in his hope that there will soon be held in Washington another international conference "for the full and frank discussion of all unsettled financial, commercial and industrial questions in which our people are interested, directly or indirectly, to be participated in by able, open-minded, well-disposed representatives from the different nations." The results of such a conference will be more effective and far reaching than the present long-range parleys among political representatives. We are inclined to the opinion that certain political matters will be soonest settled if business and financial representatives determine certain economic and industrial problems that now disturb the international prosperity.

Rules, Regulations And Esprit de Corps

ONE of the most foolish notions in business is that somebody can draw up a set of rules and then expect things to run themselves. EINSTEIN has pretty well destroyed the Absolute in philosophy, but the notion has not yet percolated into the heads of a vast number of men of affairs. A great general once gave his definition of the perfect officer as "a man who knows when to disobey orders." This holds true in industry.

A competent works manager of our acquaintance once was asked, after something had gone wrong, why he didn't post rules about the plant. He replied that his policy was to have as few rules as possible, but to see that they were enforced. Too many rules crowd one another out.

We know it is a great convenience to demand that "all letters be addressed to the company"; otherwise the person addressed may be absent or he may be the wrong person. But often it is an expensive rule, and defeats its own purpose. We have referred hitherto to the cost to a corporation involved in forbidding its salesmen to write personally to the superintendent or for him to reply personally—although it is just as easy to keep records of such letters as of those addressed nominally to the company. Here is an example of how it may work the wrong way. A correspondent writes:

> On one occasion during war time I was placed in charge of some new chemical equipment which had just been installed. None of the operating men, including the superintendent, his assistants or the engineers of the plant, were familiar with the operation of this particular piece of apparatus, for I asked them first. I finally asked permission to write to the head of the company manufacturing the apparatus, knowing the party in question personally. Permission was refused, it being against the rules, but they would do it for me. Though I asked repeatedly for any word of a reply, none was ever forthcoming and I was left to work out my own salvation. I am reasonably certain that had permission been given, I could have obtained the information desired in a few days. On another occasion with another concern where I was doing some experimental work in connection with catalysts, it occurred to me that I might be able to get some material I wanted to try out from a metallurgical concern. I had worked elsewhere with this superintendent, and had addressed a letter to him personally stating what I was after and asking for information. About ten days later the assistant manager of the firm I was with came out to the laboratory with a reply from the concern in question. It had not been answered by my friend personally, but had been turned over to someone else. This party had addressed a letter not to me, but to the firm I was with, advising them that someone in their employ had written personally for information, as though this was a crime, and, to show my offense, they attached my letter to theirs. The tone of the letter implied a rebuke to my company for permitting anyone in their employ to do such a thing.

When concerns get so big that individual members of their staff are forbidden to think for themselves or to do their best to make things move, it is time to decentralize into units that can so organize their operating forces as to achieve a real *esprit de corps*.

Cutting Capital Costs In Gas and Coke Manufacture

ONE of the greatest difficulties which the gas and coke-oven industries have faced during recent years is the very high investment cost per unit of product. It has been the ambition of all designing engineers in these fields to increase the unit capacity of installations without sacrifice of operating efficiency. The recent development of a new type coke oven described in this issue by JOSEPH BECKER seems to be an unusually successful step forward in this direction.

The seriousness of the situation in the gas business perhaps affords a more striking example of the difficulty which has been met than any which can be taken from the coke business. Previous to the war it was not uncommon for public utility companies to get money at 5 per cent and they could build the best plants then available for about $4 investment per thousand cubic feet of gas made per year. Thus the capital charge in the form of interest was only 20 cents per thousand, and other charges on capital thus invested were not excessive. In fact, it was not uncommon to find the total capital expense under 30 cents per thousand and the net operating cost was often almost nothing, for the return on byproducts frequently equaled material and labor charges for the entire process.

With the advance of money costs and the great increase in construction expenses of all sorts, the industry during the war period and since found a very different situation confronting it. In some cases money cost 7 or 8 per cent and construction costs advanced so much that $8 to $10 investment was necessary in coal-gas plants per thousand of annual output. With an investment of $10 and 8 per cent for interest alone, which are not by any means the maximum figures that were reached, the interest charge per thousand feet of gas made was obviously 80 cents. This was an almost prohibitive figure, and it is not strange that resort was had to other types of gas-making equipment in order to avoid these tremendous investments that would have been a millstone about the neck of a company for many years.

In the coke-oven business corresponding conditions prevailed, though perhaps not to such extremes. It is with great satisfaction, therefore, that one can look forward to great increase in output per oven. One example of this increase in output which is forecast

for the new type oven is given from the estimates for one of the plants now under construction. In this plant it is expected that thirty-seven ovens which cost little if any more than the earlier types will produce as much coke as fifty of the best previous type of oven. Thus at one stride the industry advances by 25 per cent. Needless to say, it is an advance that will be of great importance to users as well as to producers of this most important manufactured fuel—coke.

The Junquera Process Of Nitrate Recovery

THE U. S. consul at Iquique, Chile, contributes to a recent issue of *Commerce Reports* an account of a new process for extracting nitrate from caliche, invented by Señor BUENAVENTURA JUNQUERA. Official tests, we learn, "were witnessed by many men prominent in the nitrate industry," the result being that "there is a disposition to recognize that a new invention has been made which, when improved, may revolutionize the industry." The tacit admission that the new process is incomplete—that it needs improving—is no logical preliminary to the extravagant claims made, which include, *inter alia*, assurance that the adoption of the process will result in:

"1. An increase of ten to twenty fold in the nitrate riches of the republic, as caliches with nitrate content as low as 10 per cent can be worked profitably.

"2. Assurance to the government for many years of the collection of export taxes at the present rate without hurting the industry.

"3. Cheapening the cost of Chilean nitrate so much that the competition of artificial products will be postponed for many years."

The Chilean nitrate industry is noted for the number of its "experts." Let us examine the details of the test that convinced a group of these worthies that a new era of expansion and prosperity was at hand in consequence of Señor JUNQUERA'S invention. According to Consul BRETT, "the material is ground to pass through a ¼-in. mesh, and is then highly heated. It is placed in a battery of eight gyratory drums, each 6 ft. in diameter, and having its edge made of filter cloth. Water is forced into the center of the first drum and is driven through the material and out of the drum's edge, where it is caught and passed in rotation through all the drums. Leaving the eighth and last, it is saturated with nitrate and is allowed to cool and deposits its nitrate contents in settling tanks . . . Working with material of 12 per cent content of nitrate, the extraction was said to be total and the consumption of oil fuel was only 9½ kilos per ton, but it should be noted that this test was made with fresh water and that the various weak solutions were not worked out as they would have to be in actual practice."

The final paragraph indicates the absurdity of adopting an optimistic attitude in consequence of the "success" of an experiment such as this, for there is no reason, if dependable data were desired, why the inventor should not have used solutions of a nitrate content customary in practice. However, had he done so, the extraction would not have been "total"—by any means. It is easy to saturate water with nitrate, but it is a difficult matter to obtain saturation at a high temperature by the abstraction of nitrate from caliche and to leave a residue that contains less of value than it does after treatment in a Shanks maquina. The publication of figures indicating oil consumption during a test such as the one described is an indication of the absurdity of the claims made and given publicity by the American consul at Iquique, who obviously is unacquainted with the technique of nitrate recovery. Accounts such as this make a burlesque of the industry; they tend to discourage the entry of American inventive genius and equipment into a field that offers unusual opportunities for advancement and profit.

The Junquera system appears to lack all the essential features of a cheap and efficient process. That it can be "improved" in such a manner that the industry may be "revolutionized" will be doubted by those who are familiar with the operation and scope of centrifugals, with the handling of high-grade nitrate liquors and the economic removal, by selective solution, of a soluble salt from earthy material.

Electric Furnace In the Steel Industry

ELSEWHERE we print a brief address made before the American Iron and Steel Institute by Dr. JOHN A. MATHEWS on "The Present Status of the Electric Furnace in Refining Iron and Steel." Metallurgical engineers particularly will be interested in what he has to say, because he is one of their number who has achieved conspicuous success in an executive capacity, or, as he more aptly puts it, a siderologist turned considerologist. Furthermore, he knows whereof he speaks, for he was one of the officiating doctors at the birth of electric steel in America.

In the intervening 16 years he has had ample opportunity to study the relative merits of open-hearth, crucible and electric steel. If memory serves right, he has always been a very enthusiastic advocate of the electric furnace, but has never been willing to admit that the crucible process would be supplanted in the production of superfine steel for small tools. Even recognizing the fact that the crucible pours out only what was put in, an electric furnace will pour out nothing but mediocre stuff unless great care and keen intelligence are put into it, along with so many kilowatts. So the relative quality of the two processes is truly relative—bad steel has been produced from both; most excellent steel has been produced in quantity from both—each heat must be judged on its own merits. By and large, Dr. MATHEWS still appears to favor the crucible, quoting his own words, written several years ago:

"It is seldom that a process is discovered that cannot be improved upon. Crucible steel is an exception to this rule. This earliest process makes the best steel and has never been surpassed."

Much more interesting is the fact that he is one of the few executives in the American steel industry who have a lively appreciation of what quality in steel means, and of the responsibility of the industry in providing metal considerably better than "just good enough to get by." Consequently his words have a great deal of significance as an appraisal of the trend in the steel-consuming industries (rather than the steel-producing), and as a prediction on the future of fine steels in America:

"When users acquire a full appreciation of what clean sound steel means in terms of national efficiency, safety and economy, we shall see more rapid growth [in the use of electric furnaces] than has as yet been seen. Its usefulness to engineering and industry has just begun."

Growing Appreciation of the Value of Chemical Warfare

To the Editor of Chemical & Metallurgical Engineering

SIR:—Can it be possible that the country is beginning to regret its hasty action in so readily entering into an agreement to abolish chemical warfare? Only within the last week a Chicago newspaper twice raised the question of chemical warfare. Nor was it mentioned—as newspapers were wont to mention it—as a weapon of war to be abhorred; brutal and inhumane. Chemical warfare was urged, editorially, as a bulwark against the perils of an Asiatic invasion. A lengthy interview with ex-General von Ludendorf concludes with the forecast that the next war will be fought with the power of science rather than with multitudes of men.

With such slight encouragement shown and emanating as it does from the press, it seems all the more desirable to keep up the good work of educating the people to see the value of chemistry in warfare. Our Chemical Warfare Service is doing a wise piece of work in devoting part of its energies to the study of fumigation. The results from this work should be pushed to broad publicity.

Irrespective of what may be said against popularizing science, it must be conceded that our Chemical Warfare Service must be popularized—to use a timeworn expression, it must be "sold" to the public in general and to the personnel at Washington in particular—if we are to maintain that branch of the army in even a state of defensive preparedness. Who Financed the German Economic War?

To the Editor of Chemical & Metallurgical Engineering

SIR:—The first article on "European Conditions as I Saw Them" printed in the Oct. 18 issue of *Chem. & Met.* has raised the question: Who financed the German economic war? This very logical question can be answered by elucidating somewhat the statement that those who engineered this war, being good German psychologists, foresaw to a certainty that ample finances lay dormant first in the productive power of the German masses and second in the get-rich-quick mentality of the foreign dupes so well defined by the American expression "suckers."

That the productive capacity of the German masses has yielded vast amounts of munitions will become evident after reading the other articles (nine in all) which complete my series. They will prove that the German employees got as wages and salaries only a small fraction of what they ought to have received, were they paid the due reward for the intrinsic value of their work. This was an easy task, considering that the German masses could readily be brought to the point of believing that they were acting as soldiers and that they kept on fighting under the continuous propaganda of hatred against the makers of the Versailles treaty. They and their families were not left to suffer physical hunger, because the German Government acted as a fatherly quartermaster by facilitating their getting the strictly needed food with their minimum-for-existence pay. Similarly with their transportation and rent costs. As for the remainder of their needs and wants—well, good soldiers must not play at living *schieberisch* (like profiteers) while in active service.

The foreign dupes have contributed vast amounts of real money in exchange for German-printed banknotes. This was an indirect levy on all the world and was easily accepted because it was cloaked in the form of a get-rich-quick inducement for speculation in German paper marks. Few are the foreign bankers who did not accommodate eager clients with this made-to-order so-called German money. It is not for me to produce statistics as to what extent America, England, Holland, Switzerland, Spain and all the other countries with par money have answered the call for this indirect levy, but it is already public knowledge that America alone has thus contributed nearly one billion dollars—i.e., about twice as much as the total amount in money which Germany has thus far paid to the Allies. I may mention here that very reliable persons have told me that along the boundary between Germany and Holland Germans sell in the public markets basketfuls of German paper marks for foreign currency.

What was still needed to complete the total of the required finances was provided from the assets which the German Government still had at the close of the war. This was the first source of supply to be exhausted and was rapidly followed by sharp drops in the two other sources of supply, with the result, as pointed out in the above-mentioned article, that Germany has lost her economic war.

The productive capacity of the German working masses, which has been only sparingly paid for, the vast amounts of good foreign money obtained in exchange for their printed paper marks and the amounts contributed by the German Government to enable the working masses to subsist on their minimum-for-existence wages provided the sum total of the finances used in carrying on their disastrous economic war. Electric Welding by Alternating Current

To the Editor of Chemical & Metallurgical Engineering

SIR:—We notice on page 712 of your issue of Oct. 4 that you give space to note on "Electric Welding by Alternating Current," as being a new thing. It is new, but you don't have to go to Stockholm to find such a system.

This company holds exclusive license under patents for such an alternating current transformer welding system, the patents being granted June 3, 1919, applied for in 1917, and the development made from 1912 to 1916.

A technical description of it was given before the American Institute of Electrical Engineers, White Sulphur Springs meeting, June 29, 1920.

Newark, N. J. BY C. J. HOLSLAG.

American Iron and Steel Institute

Judge Gary Heads Notable List of Speakers at Semi-Annual Meeting—Technical Sessions Hear Papers on Fuels, Furnace Design, Fluorspar, Steel-Making Equipment and Fine Steel

EDITORIAL STAFF REPORT

ABOUT 900 steel makers and men interested in steel making assembled last Friday at the American Iron and Steel Institute's semi-annual meeting, to hear what Judge Gary, chairman of the U. S. Steel Corporation, had to say about the business outlook, and to swap views on coal, recent shows, the Kaiser's autobiography, and the way Tom Brown plays the nineteenth hole at Gadzooks. Perhaps some mention was also made of the price of pig. A hopeful sign is that the Judge made one of his few references to technology, when he remarked that we are now making steel of better quality than ever before. It appeared, also, that the listeners to the prepared papers were rather more numerous than formerly—as is fitting. No report of the committee studying the 12-hour day was presented, since it has not yet been able to collect the necessary data on its prevalence.

JUDGE GARY'S ADDRESS

The president's address was, as usual, confined to carefully chosen generalities on the business situation, both in its international aspect and as this is reflected in the iron trade. Judge Gary can see no quick relief from present high prices, since he believes that the price of commodities is made up of 85 per cent labor cost and there is no apparent possibility of reducing wage rates, except in isolated cases. The only way he sees to get away from the vicious cycle of rising prices is to suppress all conspiracies to control production, trade or labor; to refrain scrupulously from interfering with the natural law of supply and demand; and to insist upon unprejudiced and adequate publicity about business conditions and practices. Failure to observe these conditions is responsible for the only obstacles to unbounded success for the American steel industry, since we have an extraordinary amount of raw materials, transportation facilities, skillful personnel and diversified demand. Mr. Gary is opposed to cancellation of the foreign debt, likening such to "forced charity." He thinks that an international conference on economic conditions, if held in Washington and attended by such high-minded representatives as was the Arms Conference, would be of great value toward re-establishing commercial peace.

FUEL AND FUEL ECONOMY THE THEME OF TECHNICAL SESSIONS

Nine excellent technical papers were read. With two or three exceptions they referred to production, storage and economical consumption of various types of fuel. Some of those papers are without the province of *Chemical & Metallurgical Engineering*.

Some remarks made by H. Foster Bain, director of the Bureau of Mines, may help the casual reader to realize the difficulties of stabilizing the coal industry. In introducing his paper on "Modern Methods of Mining Coal," he said that business and humanitarian impulses in the coal industry were apparently quite divergent. Thus the best results may be had if a coal-mining area is equipped to work intensively, continuously and at such a rate that the coal will be exhausted in 25 years. Each such development requires the building of a town to house the workers; yet in 25 years a community has barely time to take root.

"Storage of Bituminous Coal" was another paper (by Messrs. Stoek and Freeman) which has incidental interest. Coal storage costs not less than 25 cents a ton; on the other hand, excess mining expense in slack times amounts to twice that much. Deterioration in the coal occurs at the surface only, and is therefore quite negligible in large piles. Spontaneous combustion occurs almost exclusively in fine coals, those with high FeS_2 content or those stored over timber or rubbish. Fires can be extinguished only by digging out the burning coal.

POWER PLANT ECONOMIES

It is seldom realized that the total power used in a steel mill may easily cost 5 per cent of the sales value of the finished steel, even with good utilization of by-products. This figure may be reduced by electrification —elimination of steam engines and boilers and installation of electrical generators driven by gas engines, and motor drives at all points, as pointed out by E. F. Entwisle of the Bethlehem Steel Co., in a paper entitled "Economic Importance of the Power Plant." Few plants could not reduce their total power costs and show a good return on the necessary expenditures—failure to proceed along these lines can be excused only where the same amount of money invested in other departments would show a greater return.

EFFICIENCY OF HEATING FURNACES

W. P. Chandler, Jr., of the Carnegie Steel Co., presented a paper on "Heating Furnaces for Blooms, Slabs and Billets" in which he gave heat balances for two large furnaces on such work, one continuous and the other non-continuous. The latter was built like an open-hearth furnace, fired through ports at either end, with air and producer gas preheated by underground regenerator checkerwork. Its hearth was 18x35 ft., with a burned-in silica bottom. Cold blooms varying from 5 to 10 in. square were charged through six doors, and heated to rolling temperature, 2,100 deg. F. As the furnace was unloaded, it was progressively refilled with cold material. Two furnaces are necessary to feed one rolling train. Thermal efficiencies—heat absorbed by steel divided by total heat in gas supplied—varied from 36.5 to 41 per cent, the latter occurring when heating steel at the slowest rate—viz., 32,900 lb. per hour.

Continuous recuperative furnaces showed better efficiencies. The one studied had a sloping hearth 25 ft. long and 32 ft. wide. Billets were charged and discharged endwise through small side doors, and rest on cast iron skids, not water cooled, or on a magnesite-brick bottom at the firing end. The roof is a series of flat arches. It is cooled from above by air for combustion on its way to the recuperator, after passing which it goes through passages under the hearth and then to a series of fifteen gas burners, thus acquiring a total

superheat of 325 deg. F. The recuperator consists of a series of vertical cast-iron pipes through which hot waste gases (at 1,300 deg. F.) pass on the way to the stack. Air for combustion bathes the outside of the pipes. Thermal efficiencies varied from 47 to 57 per cent, being greatest when heating 2½ in. square billets at the highest rate—66,000 lb. per hour.

A similar furnace, wherein the recuperator was built of brick tiling, gave efficiencies of 58 to 63 per cent. The increase was principally due to lower stack losses—i.e., the air for combustion was preheated 25 deg. higher, and less of it was required for correct combustion.

Various recommendations can be made, looking toward an even more economical furnace of the continuous type. Roofs should be flat, without water cooling, and placed rather low over the steel. A roof recuperator should be installed only when the roof would melt if adequately insulated. The hearth should be sloped downward toward the discharge end, and have solid cast-iron skids built in. Numerous burners will give more uniform heat distribution; each should have independent adjustments and control. Gas and air pressures at the burners should be automatically registered, and each furnace should have an accurate gas meter. Slots and swinging doors for charging or discharging the steel should be avoided on account of large leakages of cold air which always takes place. Have small doors on the sides. Metal recuperators are doubtless best; they have higher heat conductivity than firebrick, and may be made tighter. If the recuperator is properly designed, it will make it unnecessary to install a waste-heat boiler. Insulate wherever the brick will stand it. Avoid water-cooled devices.

W. P. Chapman, in the discussion, showed some photographs of special recuperative furnaces for glass making, which gave a much higher superheat and required much less air for combustion. This was done by using recuperators made of special thin-walled tiles, having small straight passages for air travel. Leakage was minimized by special joint construction and so arranging the fans that pressures on the waste gas and air side of recuperator passages are substantially equal.

Professor Trinks, of Carnegie Institute of Technology, also pointed out that the efficiency of continuous furnaces was a maximum when heating about 30 lb. of steel per sq.ft. of surface per hour. Very great heat losses are due to leakage, not only in the recuperator but by cold outside air leaking into the passageways. Unquestionably a continuous furnace should be used wherever permitted by the uniformity of shape and size of material to be heated and steady operation throughout the rest of the mill.

Liquid Fuel

A treatise on the "Use of Liquid Fuel in Metallurgical Furnaces" was prepared by R. C. Helm, of the American Steel & Wire Co. Fuel oil from 30 to 12 deg. Bé. has been used for this purpose. Flash point should be over 150 deg. F. to reduce fire hazard. Sulphur is limited to 0.75 for open-hearth melting, although after the bath is covered with slag high-sulphur oils can be used to complete the work. This involves a duplicate installation, which is not relished. High-sulphur oils will also discolor sheet brass during annealing. Solids, which clog the pipes and nozzles, are carefully removed by strainers, placed in the pipe lines in duplicate.

Oil nozzles atomize the fuel by a spray of dry steam or air at high pressure; a number of such designs were illustrated. Mechanical atomization so common in boiler practice is almost unknown, possibly because the latter throws a flaring conical flame rather than the long torch effect desired in most furnaces.

Coke-oven tar is used wherever it may be had cheaply. It is heated to about 160 deg. F., when it can be pumped about easily. Three-inch mains, steam jacketed, deliver the oil to the furnaces; sometimes a 50 per cent excess must be circulated. Special nozzles (steam atomizers) are also required. While the equipment necessary to handle tars and oils of low gravity seems quite complicated, the very low price of the fuel furnishes an attractive return on the investment.

Open-Hearth Design

One of the most notable papers of the session was on "The Thermal Efficiency and Heat Balance of an Open-Hearth Furnace," by Messrs. Kinney and McDermott, of the Illinois Steel Co., notable because it shows how thermal investigations have pointed the way in designing more efficient furnaces. We hope to give adequate space to present the details of this study in a later issue.

Various speakers urged that the Iron and Steel Institute appoint a committee to recommend standard methods for thermal studies. Apparently a great amount of this sort of work is being done, but it is not readily comparable between plants, because of variations in experimental procedure and methods of calculation. Much work ought also be done on specific heat and conductivity of refractories, metal, and gases at high temperatures.

Electric Furnaces

Dr. Mathews' important paper on "Present Status of the Electric Furnace in Refining Iron and Steel" is reprinted in full on page 872 of this issue.

Automobile Steels

A paper entitled "The Steel Requirements of the Automotive Industry" was presented by Henry Chandler, of C. H. Wills & Co. He emphasized the fact that automobile steels are bought on physical properties; even though chemical analysis is often specified, it is done only because the purchaser knows that a well-made steel of that composition will satisfy his other requirements. Tensile test is chiefly relied upon. While it by no means duplicates the service conditions (the ultimate test), when correlated with other tests and with experience it furnishes a sound basis for estimating quality. Mr. Chandler places considerable faith in the "merit number" derived from a tensile test.[1] Brinell or scleroscope tests are next in importance, giving information on machinability and the efficacy of the heat-treatment. The impact test is often used, and its chief usefulness it to check the merit number derived from the tensile test. Sometimes the microscopic constitution of the steel is so different from the expected that the above-mentioned tests give quite misleading indications—they must therefore all be interpreted in the light of full and complete information.

[1] "Quality in metal is equal to $\frac{work\ done}{metal\ affected}$ which is proportional to $\frac{mean\ breaking\ strength \times elongation}{constant - reduction\ in\ area}$, where the constant varies as the type of fracture.

Ninth National Convention of Society of Industrial Engineers

The Society Devoted Its Attention to the Significant and Timely Topic of the Relation of Economics and Business—An Abstract of the Most Significant Speeches Reflects the Progress Being Made Along These Lines

EDITORIAL STAFF REPORT

PLEASE consider this a kind of official introduction to the Society of Industrial Engineers. The organization of this society was significant, and its work continues to be significant. It is indicative of the increasing attention which is being devoted to the problems of scientific management in all of its phases. Chemical industries have suffered and still do suffer from a lack of contact with the principles of scientific management. This statement does not mean, of course, that many chemical companies are not well managed. That would be absurd, but if they are well managed, it is probably due to a rather empirical development than to a careful study of management principles as such. It is therefore high time that the attention of these industries should be turned to a group which is devoting its energy to the study of these principles and to the development of new ones.

PRESENT STATUS OF ECONOMICS IN BUSINESS

The meeting in New York last week took for its text the economics of industry and intended to develop such fundamental economic principles as were necessary to maintain maximum production with a minimum effort, waste and cost. President Joseph W. Roe, head of the department of industrial engineering at New York University, gave the keynote speech. There is, he remarked, a close analogy between the attitude of the manager of an industrial plant of today toward economics and the attitude of the plant manager of 50 years ago toward the study of science. The attitude runs its course from an amused tolerance to a distinct distrust, with enough significant exceptions who take a serious interest in the subject and who make it worth while to study the exceptions. Fifty years ago these exceptions, the men who pinned their faith on the scientifically trained engineer, soon made it apparent that industrial waste and mechanical inefficiency which were then so universal could not be tolerated. It is now a paramount question to eliminate social waste in industry. Nearly all waste in industry is now due either to bad management or social causes. It is of course legitimate to point out that good business men are often ignorant of economics, but so too were the good practical engineers without scientific training a generation and a half ago. With the present complexity of industry, the economist becomes essential. He sees forces in perspective which the individual manager can but vaguely feel.

Let us take as an example a single economic law, the law of diminishing returns, and study industry to see in what ways this law may operate. The first example has been multiplied so many times in the last 2 years that it is almost a redundancy to mention it. Overproduction is inevitably and invariably a result of a disregard of this economic law. Another variation of this law is the possibility of an economic limit to the size of a business. One conspicuous example will develop the idea which lies behind this. Holmes of the Waterbury Valley is a name to conjure by in the brass industry. During the middle of the last century he started five successful enterprises which are still in existence. He believed that a thousand employees was the right size of any individual unit in the brass industry, and when he reached a thousand employees he started over again. Therefore the continued success of these five enterprises is noteworthy and makes very pertinent the question, Can we overdo size?

We must bring industry and economics together, concluded President Roe. First, let the labor leaders and industrial men read economic history and study its cycles. Let there be more readable economic books and sound economics taught, not only in colleges but in schools. Business men should be taught to use the present statistical sources and through their trade associations to study economic problems, including such things as the sources, quantities and prices of prime raw materials, not only in their own industry but in other industries.

ECONOMICS PART IN FORMING BUSINESS POLICY

Another keynote speech was made by J. H. Pardee, president of the J. G. White Management Corporation. From his wide experience he picked out the functions of economics in forming a policy of business administration. Business men today are gamblers, most of them, he said, largely because they do not study the fundamentals of economics and their application to their own business. There was in his opinion one great need in economics at the present time, and that was standards throughout the science. Mr. Pardee pointed out that chemistry, physics and astronomy made little advance until standards of measurement were adopted, and finally developed the very significant analogy that very little progress was made by the Interstate Commerce Commission on railroad problems until it had thoroughly standardized procedure, nomenclature and measurements. It was notable, he pointed out, that such problems as tariff, taxation, etc., find astute business men on opposite sides. This, he felt, was due largely to the fact that the definitions in this field did not define and that there is a distinct lack of adequate standards. With proper standards the many problems which now confound the business man would undoubtedly be ironed out. He would be able better to understand the law of supply and demand in relation to his own business. He would see that selling price and cost of production were interrelated. He would understand the fallacy of a fixed overhead and more than 10 per cent of the manufacturing establishments (the present ratio) would see the vital necessity of adopting cost accounting systems.

The Employer-Employee Relation

Two questions which primarily involve the employer-employee relations were discussed ably and at some length at one of the sessions. The discussion took the

form of answers to two questions. First, how can we reduce production costs, and, second, what keeps the workers contented? Each of these questions was discussed, first through a paper designed to represent the employer's point of view, and then with a paper presenting that of the employee. James A. Faust, of New York City, pointed out the significant fact that chief executives are usually somewhat unbalanced. This is not at all strange, for, of course, a chief executive develops through one of the individual departments, either sales or cost or production, and it is therefore quite understandable that his department of the work would be more emphasized because he was more familiar with it when he became chief executive. Mr. Faust claimed that the chief executive was the chief factor in cost reduction. Charles M. Schwab once said that he had no high-priced executives in his company, but he had the best paid executives in the country. The way he attained this peculiar situation was by paying them a bonus; for any man, he said, can produce pig iron for, let us say, $1 a ton, and that was what he was paid his salary for, but if he produced pig iron at 95 cents a ton, then he would receive 5 per cent of the net saving that he had made, and so on. If the chief executive cannot pass on an enthusiasm and a faith in the organization down to the lowest workman in the plant, that organization will fall short of its highest efficiency by just so much.

The Big Problem of Co-operation

From the worker's standpoint Mr. Geiger of the Keratol Co. pointed out that costs could be reduced by using the workman's time to better advantage. The worker has three things to give a company—time, skill and co-operation. Of these time has up to the present received by far the greatest attention. Time charts, man charts, etc., are becoming better and better known, but it must be remembered also that unused skill is as expensive as unused time, and if for reasons of poor co-operation a workman is not stimulated to use his best skill and thought for the company, then that company is not using that workman to either its or his best advantage. Co-operation is that easiest and hardest thing to obtain, and it is extremely necessary to the efficient use of the worker's energy. A suspicious worker is not a good co-operator, and a worker will become suspicious if he feels that for some reason or other he is not getting his just due. Wages alone, be they high as the sky, and fancy cafeterias do not make a good place in which to work.

The second question, how to keep the worker contented, was answered from the standpoint of management by Charles Cheney of the Cheney Brothers Silk Manufacturing Co., South Manchester, Conn. He pointed out that it was necessary to go back to fundamentals before this problem could properly be studied. What is contentment? Above all, it should not be sedative, and it should not stifle the creative impulse which exists in every man, be he workman or executive. The welfare worker is looked on with suspicion, because welfare work has been undertaken so often in a narrow spirit, demanding a plastic submission. Does it pay to do welfare work? He hoped so, but he felt the proof was lacking. Another question, the answer to which was also more or less indefinite but which he also hoped was true, was, Does it pay to be honest? The sore, aggrieved worker is a menace, and he must be eliminated, not by being kicked out, but by being taken into the confidence of the organization management, by being made an associate. Then, treated as an associate, he must receive his due.

What is his due? Again, we must get down to fundamentals. Compensation should vary with the results received, but should vary with the results obtained by the individual and not the results obtained by the business. The amount of compensation should first of all insure a margin of safety above decent living. Such extra compensation as is in order should be based on individual efforts, should be large enough to strive for, should be paid soon enough to make the worker realize just what effort is necessary to accomplish that result and should be paid on a system simple enough to be easily comprehended. It is not generally known that such a system of compensation has been applied as well to clerical help as to mere manual or machine labor. In addition to such a basis of compensation based on efficiency, Mr. Cheney recommended a credit rating plan, adding a bonus for good citizenship, for marriage, for service, as well as for efficiency. In other words, the value of a man to a firm will vary in respect to these things, and therefore it is reasonable to vary his compensation on that basis too.

Profit sharing, as it is practiced at the present time, is not logical. It is a present and nothing more. The statement that labor makes profit he believed to be inaccurate, for he felt that labor had almost no connection with the profits of a business. Labor could be faithful, could give his own best energy and yet the business might fail, due entirely to poor purchasing, poor sales policy, economic conditions, strenuous competition, poor advertising or any number of other items over which the individual worker has no control. The fact that he has common interest with the firm does not make him a partner in the firm. Furthermore, profit sharing has not worked out well in practice. The advantages gained at first are soon lost, and the profit-sharing bonus is expected as regularly and counted on as definitely as ordinary wages. Many firms have found it extremely difficult to discontinue profit sharing in bad years. Furthermore, Mr. Cheney felt that in general the investing of the employee's money in the business was not wise and somewhat dangerous.

The worker should be dealt with on a basis of justice, plus consideration, sympathy and human interest. It must be reciprocal, and the method of accomplishing this is by personal work rather than by any cut and dried system. Labor does not want to lead, but is willing to be led if kindly led. His thoughts must be expressed somewhat and should be expressed for the benefit of the firm, and his aspirations must be considered and made to coincide as closely as possible with the interests of the firm itself. When this identity exists, the state of that corporation will be healthy.

Partly in reply and partly in extension of the remarks of Mr. Cheney, O. A. Prebble, who has been an officer in the American Federation of Labor and has been connected with labor problems for a long time, presented what might be considered labor's views. With Mr. Cheney, he felt that labor wanted justice more than anything else. He did not want presents or patronage or even consideration—but justice.

Economics and Production

From the standpoint of the engineer the most immediately appealing subject on the program was that covered by Ernest F. Du Brul, general manager of the

National Machine Tool Builders' Association, "The Economic Aspect of Production." The problems of production and the vocabulary of production are familiar to the engineer and therefore hear what he has to say!

The Engineer's Contact With Economics

The engineer thinks of the fabrication of physical goods when production is mentioned, but there is danger in this point of view. The danger is that he will and does consider that when goods are fabricated, value is created. True, money has been expended in fabrication, but there is no value until a market has been obtained. In other words, production of utility, which is the thing of value, must not be dissociated from distribution and financing, else we begin to have the unbalanced view that: "The producer gets too little out of what the user finally pays," and "Labor produces all wealth." Accordingly they begin to think that simply by fabricating or growing something, they are entitled to demand other goods and services in return for theirs.

Another point in which the fabrication man's logic has slipped a distinct cog is in adhering to the fallacy, "The more the output of the plant the lower the cost and the greater the profit." This does not follow and many an engineer has urged greater production when it resulted ultimately in increased cost, and even when costs were lower a market was often not assured. Even so it has been in many industries. The rubber tire industry suffers today from a large overhead which it must carry. The market was estimated to be nearly double its actual extent.

Different businesses will require widely different policies. Standardization of their patterns would be fatal where standardization of a make of automobile is vital. An expert aviator may know nothing of the physics and thermodynamics of engines. Yet both the expert in construction and design and the aviator are essential to the progress of aviation. So with the economist and the business man. The one must discover and the other apply economic laws to the business machine. More, more and still more economics will be essential to proper and effective progress.

Other Convention Activities

In abstracts of these few keynote speeches we have reflected the outstanding spirit of the meeting. There were many other papers presented, prominent among which were "The Budget and the Financial Forecast," by A. J. Lutterbach, controller of the Palmolive Co., and "The Necessity of Waste Elimination to the Economic Structure," by Robert B. Wolf.

There were group meetings on a variety of topics: The Economic Background of the Executive; The Measurement of Management; The Reduction of Sales Costs; Is There a More Scientific Method of Selecting People for Jobs? The topics were interesting, but in general the discussion fell short of the high plane of the addresses. The discussion was not animated in those groups attended and the matter brought out was usually nothing more than casual. With that reservation, however, the meeting was thoughtful, timely and stimulating. Give the society your attention. We believe it will merit it.

Prof. J. W. Roe was re-elected president of the society and announced that the next convention would probably be held in Buffalo during April of next year. No subject has been chosen as yet for the meeting.

Status of Italian Artificial Silk Industry

The Italian artificial silk industry has attained a considerable development as regards capital invested, labor employed, raw materials and actual production, says *Commerce Reports*, Sept. 25, 1922. The industry is a comparatively new one, being unkown in the world's market for only 30 years and in Italy for about 15. All four known processes are used—nitrocellulose, cuprammonium, cellulose acetate and viscose.

Amount of Capital and Labor Involved

The present amount of capital involved is about 420,000,000 lire (approximately $21,000,000 at current rate), and by the end of 1923 it is estimated that the amount will be fully double that figure. Twelve thousand laborers are now employed, and by the close of 1923 it is estimated that the number will be about 20,000. Some of the raw materials used—i.e., soda, carbon bisulphide and sulphuric acid—are produced by native industries, and it is hoped that after a time the wood pulp may be also, though at present it is imported principally from Scandinavia. Considerable quantities of cloth, hosiery and knitted goods are being manufactured from the fiber.

At present there are five large factories in Italy—located at Pavia, Padua, Venaria Reale and Cesano Maderno, which produce in all 24,250 lb. of artificial silk per day. These figures are furnished by the Associazione Nazionale Seta Artificiale. It is estimated that, with the possible increase in the production of the old plants and with the two new large factories in the course of construction at Rome and Naples, the present production will be more than doubled.

Importation Despite Large Domestic Production

The rapid increase in the uses and consumption of artificial silk justifies the great increase in production, says the *Bollettino di Notizie Commerciali*. At present the factories do not meet the national demand, as they have a considerable export trade. Consequently there is quite an import trade also. The imports come at present from countries of high exchange conditions—which are also the greatest and best producers and exporters—as the German production is insufficient to meet the needs of its own market at home.

The export trade is constantly increasing. This is doubtless caused not only by the quality of the Italian product, but also by the exchange situation, as the trade is directed almost exclusively to countries where money has depreciated very little, if any. The latter element is, of course, of transitory character and a change in currency conditions or the revival of competition by a country with lower exchange than Italy (for example, Germany) might alter the situation greatly.

Study of Electric Furnace Refractories

As it is hoped to develop refractories for electric furnaces, it is desirable to have a method and apparatus for measuring their conductivity at advanced temperatures, states the Bureau of Mines. Moreover, data in regard to the conductivity of existing refractories at temperatures above 1,400 deg. C. are meager. It is proposed by the bureau to study the leakage factor through refractories. The method of attack has been worked out and the furnace designed, the material for which is arriving at the bureau's ceramic experiment station at Columbus, Ohio.

The Present Status of the Electric Furnace in Refining Iron and Steel*

Flexibility of Furnace and Quality of Output Have Established the Position of the Electric Furnace—As Consumers Realize the Economy of Using Clean, Sound Steel, They Demand an Increasing Tonnage of Electric Steel

By John A. Mathews
President, Crucible Steel Co. of America

IT SEEMS to have been generally overlooked by the steel trade that this year, 1922, marks the tercentenary of iron making in the Western Hemisphere. In 1622 the first iron was made at Falling Creek, Va., and in the same year the plant was destroyed and the workmen massacred by the Indians. It is a far cry from charcoal hearths and forges to the consideration of the electric furnace—the latest development in steel-making processes.

Optimistic Predictions of Inventors

The earliest literature of electric melting of iron and steel dates back but a score of years and was provided by the inventors of various furnace types. It is characterized by the enthusiastic optimism of the inventor, and on that account may not have been considered very seriously by conservative, practical steel men. Their confidence in electric furnaces may not have been greatly increased during the next few years by the writings (including my own) of those who made the earliest installations. They may have felt that there was something of the child-with-a-new-toy air about them, and that both inventors and early users were overstating the case and that time and further experience might change matters. The war needs stirred some of the doubting Thomases to action and furnaces were installed in great numbers, particularly in the years 1917 and 1918. So rapid was the introduction of electric furnaces at this time that I felt constrained to utter a word of caution in a previous paper to this Institute[1] when I said: "We will pass through a period of reaction and dissatisfaction with electric products while many of the new furnaces are in the experimental stage."

This opinion was based upon the fear that furnaces could be built faster than skilled operators could be trained. I now feel that my fears were justified by the experiences of the war period, for much electric furnace product was not what it should have been, and possibly not as good as much of the open-hearth product produced during the same period. I have always discouraged the idea that the electric furnace was a foolproof and automatic process for making superior steel by those unskilled in steel making.

Importance of the Method at Present

I believe now that the period of disaffection is past and that the 16 years of experience since the first electric furnace was installed in America, at the Halcomb Steel Co., have been sufficient to afford a sounder basis of judgment than may have been afforded by the earlier literature already mentioned. There are now nearly 1,000 electric furnaces in America and Europe, not quite half of them in the United States and Canada. Constant interest in these developments from the beginning leads me to feel that the pioneer writers were not overenthusiastic and that their claims and predictions have, in general, been fulfilled.

It will surprise many of you to know that Italy has about 180 electric furnaces for steel melting, and that 27 of them are from 15 to 25 tons capacity, and in 1921 her tonnage of electric steel was second only to that of the United States and reached a new high mark for that country. The annual productive capacity there is about 1,000,000 tons, and Dr. Giolitti recently told me that some of these furnaces were operating at unusually high speed and with great economy of electrode consumption, as low as 6½ lb. per ton for cold melting. For installed capacity, Italy ranks ahead of Germany, England and France, and second only to the United States.

The rapidity with which electric furnaces have been installed within the last decade all over the world calls for some analysis as to cause. After 10 or 12 years of invention and pioneering there were about 125 furnaces in the world in 1912. At this time Germany led with nearly one-third of the total number. Today, as nearly as may be estimated, there are 1,000 furnaces, 388 of them being in the United States according to the *Iron Age* figures for Jan. 1, 1922. Accurate statistics have been extremely difficult to secure during late years, but according to Dr. Richard Amberg[2] there are 65 furnaces in Germany engaged in the manufacture of ingots, with a yearly productive capacity of 430,000 tons, and an unknown number of furnaces making steel castings, with a capacity estimated at 300,000 tons per annum. I think we may estimate the total number of electric furnaces in Germany as about 100 to 110.

Flexibility of the Electric Furnace

The reasons for the world-wide expansion of electric steel making are three:

(1) Cheapening of wholesale power rates, due to hydro-electric and improved steam plant developments. Thus it is now commercial to use electricity for melting, whereas the original promoters of arc furnaces felt that their use would be of necessity confined to refining of metal premelted by the older processes.

(2) The extreme flexibility and adaptability of electric furnaces to a wide range of uses. It has been shown by experience that they may be successfully used for melting cold charges or refining liquid charges, for making ingots or castings, and for melting ferro-alloys. They may be used alone, or in conjunction with the bessemer or open-hearth, or both. They may be operated acid or basic. They may be used in conjunction with the blast furnace or cupola for making gray-iron, malleable and semi-steel castings. For foundry use particularly the small units are advantageous for making frequent small heats of steel or iron castings.

*Paper read before the American Iron and Steel Institute at New York, Oct. 27, 1922.

[1] "The Electric Furnace in Steel Manufacture," Yearbook American Iron and Steel Institute, 1916, p. 73 (May, 1916).

[2] "Electric Furnaces in the Iron and Steel Industry," *Helios*, vol. 28, p. 169, for April, 1922.

The most popular size of electric furnace in this country is of 6 gross tons capacity, but furnaces from ½ ton to 40 tons capacity have proved equally successful. In furnaces of 6 tons or a little larger hand charging is general, but in the larger sizes either mechanical charging of cold materials or the use of hot metal charges is usual. Duplexing of open-hearth steel is practiced in many of the larger units, while triplexing is done at the great installation at the Illinois Steel Co. as described at the Institute a few years ago by T. W. Robinson.[3]

All of the manifold methods of operation are possible with the use of arc furnaces, which are by far the most frequently used here and abroad. Of the different types of arc furnaces in the United States nearly one-half are of the Heroult type and considerably more than one-half of the productive capacity is represented by them.

The electric furnace has small possibilities in this country for the manufacture of pig iron from the ore, but during the war period several furnaces were used to make so-called synthetic pig iron from turnings and borings and other light scrap in the United States, Canada and France. In Sweden, Norway and Italy, where metallurgical fuel is very dear and electricity is cheap, electric smelting of ores is an established industry. The world's production for 1921 is placed at 377,000 tons, and most of you will recall that the year 1921 was not a good year for high records.

Quality of Product

(3) Quality of products. A new process to succeed must be cheaper in operation or produce a better quality. The cost of electric steel is rarely lower than open-hearth and never lower than bessemer, and therefore its success is presumably due to its producing a generally superior product. Of course there are especially favored localities or peculiar market conditions which warrant the installation of small electric furnaces where open-hearth and bessemer installations would be out of the question. In the same localities and markets electric furnaces do operate successfully alongside of large-tonnage plants, and under such conditions quality must be the principal reason for success rather than low cost.

It is quite obvious that this country has not installed 1,500,000 tons of productive capacity to compete with the present crucible capacity of one-tenth that volume. In an address several years ago I said: "It is seldom that a process is discovered that cannot be improved upon. Crucible steel is an exception to this rule. This earliest process makes the best steel and has never been surpassed." The superior lasting qualities of German guns was often ascribed to the use of molybdenum, zirconium, uranium or other strange alloys, but my own idea is that the use of clean, well-melted crucible or electric steel is a more probable explanation. Crucible steel was employed for many submarine crankshafts, and apparently the Germans recognize that when fabricating and machining costs are far in excess of material cost, and where dependability is a vital necessity, it is a poor policy to save at the spigot and let out at the bunghole. Quality depends upon the selection of raw materials, the process of melting and subsequent care in forging and heat-treating. The electric furnace provides a reducing atmosphere in which sulphur is readily removed and with it goes one of the generally recognized inclusions, manganese sulphide, and the same condition serves to eliminate oxides.

The electric furnace, therefore, is a potential source of clean steel which is more highly appreciated than formerly, and the electric product is opportune to meet the new and exacting requirements for ordnance, automobiles and airplanes, and other devices in which alternating stresses are very severe. The importance of clean steel has been observed in the course of extensive investigations of the fatigue of metals under the direction of Prof. H. F. Moore. It is not too much to expect that the higher the elastic or proportional limit resulting from heat-treatment the more serious would become defects such as non-metallic inclusions and seams in parts made from inferior steel. Dr. McCance confirms this in stating that fatigue failure under repeated stress is a progressive failure, starting in all cases in some defect or irregularity either of internal structure or external surface.

Freedom From Inclusions

By way of illustrating the freedom from inclusions in electric steel, I might mention the result of actual count of hairlines, due to inclusions, in the ground surface of steel to the same chemical specification—a chromium-nickel steel for airplane crankshafts. As the result of tests on several heats of this steel by the basic, and acid open-hearth and basic electric process, the average count ran in the ratio of 8 to 4 to 1, and the hairlines in the electric steel were much shorter than in the steel of open-hearth manufacture. Another illustration from my own experience may be convincing. In one of the races at the Indianapolis Speedway a few years ago, about one-half of the cars starting did not finish because of failure of vital parts. The following year nine or ten cars, which I knew contained our electric furnace product in their important parts, all finished the race without mishap, and included the winning car. A practical demonstration of this kind is more eloquent than columns of figures of laboratory tests. The recent paper by W. J. Priestley[4] outlines the splendid results of electric furnace ordnance steels made at Charleston, W. Va., in the largest furnaces in the United States. He shows that the results are due to clean steel and freedom from oxides, sulphur and phosphorus. These results show that large units, with proper handling, can produce very high-quality steel, and we see no reason, now that larger electrodes can be made of dependable quality, why a 60- or 80-ton furnace cannot be expected to give relatively as satisfactory results. The electric steel rail is still a desired possibility. The increased demands made upon materials of construction call for new methods for meeting those demands. As I stated here 6 years ago, the electric furnace was opportunely invented to meet a new demand rather than to replace an old process.

Recent Improvements

It would be mere repetition to restate here the various types of furnaces, such as arc, induction, radiation, etc. They have been described in books and technical magazines and we need only observe in passing that there have been no new principles of heating employed since the first few years—with the possible exception

[3] "The Triplex Process of Producing Electric Steel at South Chicago," Yearbook American Iron and Steel Institute, 1918, p. 115. Reprinted in *Chem. & Met.*, July 1, 1918, vol. 19, p. 15.

[4] "Effect of Sulphur and Oxides in Ordnance Steel," *Trans.*, A.I.M.E., vol. 67, p. 317 (1922). Abstracted in *Chem. & Met.*, vol. 21, p. 259.

of Dr. Northrup's high-frequency induction furnace[5] which has not thus far been successfully employed in units of commercial size in the steel industry. Of mechanical and electrical refinements there have been many, all in the nature of improvements in regulation and economy. Among these may be mentioned two of American origin, J. A. Seede's automatic electrode regulator and E. T. Moore's peak-load regulator. The principle of dual, or rather multiple, voltages was embodied in our original installation in 1906, but its metallurgical significance was not so apparent as it was later when we installed a process employing a 220-volt arc and with considerable difficulty succeeded in persuading the inventor that provision for a lower voltage for use during the refining period must be provided. The desirability of relatively high voltage for melting and low voltage for refining is now generally recognized. Many improvements have been made as the shortcomings of the earlier furnaces appeared, such as well-fitting doors, water-cooled arches, better electrodes and holders and economizers to cut down oxidation and waste of the electrode. I have seen electrode costs per ton of product as high as $8 gradually decline to 35 cents. This was in a furnace refining molten charges.

Possibilities of the Future

The electric furnace is also a recognized factor in melting non-ferrous alloys, such as brass and Monel metal, as well as special alloys such as "Nichrome," "Rezistal," "Stellite," stainless steel, manganese steel and high-speed steels, besides an endless variety of the simpler alloy and carbon steels from the mildest to the hardest tempers. As stated earlier in this paper, its astonishing flexibility—versatility, we might call it—has attracted the attention of the metallurgical world in almost every branch of smelting, melting, refining, heating and even baking metals. To those of us who have watched its growth from the start, it seemed very slow in achieving the recognition we felt must inevitably come to it, but at last our early confidence has been confirmed in every steel-making country, because its products have fulfilled almost every expectation in every field wherein it has been thoroughly tried. The present success is due not only to the original inventors of the basic processes but also to the active co-operation of the great manufacturers of electrical equipment, furnace designers and builders, makers of refractories and electrodes and a group of earnest metallurgists in many plants who have studied every detail of operation.

When users acquire a full appreciation of what clean sound steel means in terms of national efficiency, safety and economy we shall see more rapid growth than has as yet been seen. Its usefulness to engineering and industry has just begun.

New Basis for Chilean Nitrate Prices

At a reunion of the nitrate producers, held in Valparaiso, Chile, and reported by Vice-Consul B. C. Matthews, of Antofagasta, Chile, it was decided to eliminate the confusion resulting in quoting prices in Spanish quintals by making all future quotations on the basis of the metric quintal of 100 kilos. On this basis the following prices have been fixed for the year 1923: from Oct. 1, 1922, 20s.; from Oct. 16, 1922, 20s. 6d.; from Dec. 1, 1922, to April 20, 1923, 20s. 8d.; May, 1923, 19s. 9d.; and June, 1923, 18s. 6d.

Effect of Manganese in Steel

Some work has recently been done at the Bureau of Standards on an extensive series of low-manganese steels with carbons ranging up to 1.6 per cent and manganese up to 2.0 per cent, prepared of pure materials, in order to determine the change in physical properties caused by adding manganese to plain carbon steels.

The effect of manganese, as observed in annealed alloys, is to confer upon the pearlite a very fine grain or sorbitic structure, even after slow cooling. The relative amount of pearlite present is considerably greater in the alloys of high-manganese content than in corresponding ones low in this element. The addition of manganese causes a shift in the eutectoid ratio toward lower carbon content. One per cent manganese lowers it to approximately 0.78 per cent carbon.

A pronounced increase in Brinell hardness of the annealed alloys accompanies the change in structure produced by the addition of manganese.

In the normalized alloys, a pronounced decrease in grain size was found in those of high-manganese content in addition to the structural effects mentioned above. In the annealed specimens, no noticeable difference in grain size was detected for high- and low-manganese content in alloys of any given carbon content. The well-known effect of manganese in lowering the transformation temperatures of the materials will account in part for the observed structural changes.

It appears also that manganese renders steel more sluggish and less responsive to structural changes than many of the other elements which produce a similar lowering of the critical temperatures. While the results of the structural examination will not warrant any definite conclusions concerning the use of manganese as a strengthening element in steel, the results obtained strongly support previous recommendations which have been made by different metallurgists concerning the advantages to be gained from the use of higher manganese, particularly in low- and medium-carbon steels.

German Potash Situation

Commerce Reports for Sept. 25, 1922, summarizes the German output and domestic consumption of pure potash as follows for the years indicated below:

Years	Output, Tons	Consumption, Tons
1913	1,110,362	557,000
1921	921,146	720,000
1922 (estimated)	1,250,000	850,000

There has been an increased use of potash in fertilizers for German soil because of the shortage of phosphoric acid. Only 268,000 tons of phosphoric acid was applied in 1921, as compared with 630,000 tons used in 1913.

It is estimated that the former German potash mines in Alsace will yield 120,000 tons of potash in 1922 and that the Alsatian export capacity this year will be from 50,000 to 60,000 tons, while the German export capacity is estimated at 400,000 tons.

The reported accord between German and Alsatian potash groups to establish a monopoly and raise prices has been denied by officers of the German Potash Syndicate.

The German price of muriate of potash c.i.f. American Atlantic ports is now $32.95 net per ton, as compared with $35 in 1913; and kainite is quoted at $6.70 at present, compared with $7.50 in 1913.

Modern Byproduct Coking

By Joseph Becker
Consulting Engineer, the Koppers Co.

*With Special Reference to the New Koppers Combination Oven**

BEFORE entering into the subject of this paper, perhaps it would be well to mention briefly the remarkable development which has taken place in the byproduct coke industry in the United States in the past decade, particularly in its relation to the iron and steel industry, with which it is so closely identified.

Not quite 15 years have elapsed since the United States Steel Corporation installed its first byproduct coke plant of Koppers design at Joliet, Ill., and since blast-furnace operators were looking with doubt and suspicion on the byproduct coke oven as a source of blast-furnace fuel; but in this comparatively short time the byproduct coke oven has come to be an essential part of an economically operated iron and steel plant.

European Coking Practice

It is no idle boast to say that American byproduct coke-oven practice leads the world today, this despite the fact that the byproduct coke oven originated and was in general use on the continent before it was even thought of in the United States. The writer had an opportunity last year to visit Europe and to study European byproduct coke-oven operation very carefully. What he saw convinced him that European practice is 10 years behind ours. That very little, if any, progress has been made there in the past 10 or 15 years is brought out very clearly in an article in the Sept. 2 issue of *The Gas World* of London, describing an installation of 100 ovens for the purpose of carbonizing 540 tons of coal per day. This article goes on to say that the plant previously consisted of 100 horizontal-flued waste-heat ovens which have been in operation for 15 years. These ovens have a capacity of 7 tons and the 100 ovens carbonize 500 tons of dry slack coal per 24 hours. This would be equivalent to 31 hours' coking time. The additional 100 ovens recently completed are of the vertical-flued type, and have a capacity of 7½ tons each, with a carbonizing capacity of 540 tons of dry slack per day. This would be equivalent to a coking time of about 33 hours.

This very strikingly shows that at least in this plant no progress has been made with respect to increasing the coking capacity per oven. It is remarkable that after 15 years a new plant is built which has even less carbonizing capacity per oven per day than the old plant, in spite of the enormous progress that has been made in the United States during the same period in the way of increasing oven capacity. This is merely citing one instance of English coking practice, and the majority of English coke plants operate under very similar conditions.

The writer observed similar things during his last year's visit in Germany. There have been recently put into operation ovens of the Koppers type, which are heated with blast-furnace gas and which are supposed to operate on 18 hours' coking time. These have an average width of about 16 in. and a length of about 32 ft. between doors, making a carbonizing capacity of about 14½ tons per oven per day. This is very likely the largest capacity of any type oven of similar dimensions in Europe. However, even this capacity is low when compared with American coke-oven capacities. Modern American ovens carbonize more than double the quantity of coal per day that can be coked in ovens as built in Germany and England.

Difference Between European and American Practice

The question now arises, What is the reason for this great difference in coking speeds? Many have been advanced by our European contemporaries, the most prevalent of which is that they have to carbonize wet-wash coals and that this makes it impossible for them to attain the same coking speeds possible here. This does not sound quite reasonable, and furthermore, it is a fact that several plants in this country are using washed coals averaging 12 per cent moisture and more, and carbonizing them in from 15 to 17 hours in Koppers ovens averaging 17 in. in width.

Another reason given is that the character of their coals is quite different from those found here. The writer has made an examination of the analyses and coking qualities of the various coals found there, and in general they correspond very closely to the coals found in this country, so this argument does not seem to hold.

Most striking proof of the fallacy of both these arguments was given during our recent coal strike, where several companies operating byproduct coke plants imported large quantities of English coals to avoid curtailing operations. The Seaboard Byproduct Coke Co. at Jersey City, N. J., received over 100,000 tons of English coals such as Yorkshire and Durham coals, and coked them in 16 hours continuously with the same ease as other American coals of different varieties used there, producing coke of very good quality for metallurgical purposes (see Figs. 1, 2 and 3). About 100 tons of Yorkshire and Durham coals were sent to the Chicago Byproduct Coke Co.'s coke plant and separate coking tests were made in the new five-oven battery. These coals were perfectly coked at a coking time of 11 hours without the slightest difficulty and the coke produced was just as good for blast-furnace use as any coke made in the Pittsburgh district from Pittsburgh coals. (See Figs. 4 and 5.) The capacity of this oven on these coals is, therefore, 25 net tons per oven per day.

Unquestionably one reason for their not being able to attain our coking speed is the fact that they do not generally use silica construction. On the other hand, there are ovens of this material over there; but these have not attained anything approaching American practice.

Organization the Keynote of Operation

The organizations operating the coke ovens in America consist generally of technically trained men with good practical experience, the latter not being gen-

*Abstract of paper presented at the recent meeting of the Eastern States Blast Furnace and Coke Oven Association at Buffalo, N. Y.

Fig. 1—Coke from 100 per cent Yorkshire coal coked at Seaboard Byproduct Coke Co.

erally the case in Europe. American operators have more tenacity in solving problems and difficulties in organization and operation in order to attain greater capacities from their plants and do not offer excuses for inability to maintain a high output as is done abroad.

One of the most important features of organization to be found on American coke plants is the strikingly systematic operation of the ovens. Ovens are heated by intelligent heaters and most of the assistants and superintendents of American plants have passed through the entire school of byproduct coke-oven operation, beginning as heaters. Even in cases where this is not so the assistants and superintendents fully realize the importance of even heating and consider the oven operation the "heart" of the entire byproduct coke plant.

In European operation, on the other hand, insufficient talent and talent of a lower quality are employed to take care of the ovens. The result is that coke-oven batteries need frequent repairs and relining, often after only 3 to 5 years of operation. In making this statement I do not refer to plants using highly expanding coals or coals containing excessive amounts of sodium chloride and which are coked in clay ovens instead of in silica ovens. The usual class of heaters employed in Europe are men who are not acquainted with combustion problems and who operate the ovens by rule-of-thumb methods. In most plants it will be found that there is no pushing schedule at all. Ovens are picked out and pushed as they become ready, so it can be stated as a general rule that the ovens on the continent operate the heaters, while in America the heaters operate the ovens.

Another excuse usually offered is that with our fast operation we destroy byproducts. The writer had an opportunity to investigate this and finds that the byproduct yields here are fully equal to those obtained in Europe.

Tendency of Modern American Designs

The development in America has been a gradual increase in the size of the ovens. The use of high-grade silica throughout the structure has reduced the time required for coking considerably as compared with the use of clay bricks. But beyond the increase of capacity due to the use of silica in the building of long and high ovens there was necessary an improvement of the design of the ovens proper to make it possible that long and high ovens could be built with proper heat distribution over the considerably increased coking areas.

The problem of designing ovens which would assure a perfect distribution of heat over such large areas was a difficult one. A great number of coke plants were desirous of coking 100 per cent high-volatile coals. The blast-furnace practice showed that coke made from such coals should be pushed at relatively lower temperatures. When pushing coke made at low temperatures, any uneven heating conditions in the ovens becomes much more pronounced and visible than when pushing hot coke. Furthermore, it is a matter of course that the heating system of ovens of large capacities has to permit passage of larger volumes of gas such as waste products of combustion through their flues.

Testing for Coking Temperatures

Fig. 6 shows a typical progression of temperature into the coal charge at various places in such an oven. These readings were taken by inserting thermocouples through the pusher side door 4 ft. into the coal charge; one was located 2 ft. above the oven floor, one just below the horizontal flue and another one at about the center line of the horizontal flue.

The figures given herein are an average of a great number of readings and exhibit in general the conditions as they exist in practically all the Koppers coke ovens which are heated reasonably well and operated to capacity. This indicates that the space occupied by the horizontal flue is quite appreciable and the amount of coke in the upper region of the ovens being affected by

Fig. 2—Coke from 100 per cent Durham coal coke at Seaboard Byproduct Coke Co.

Fig. 4—Coke from Yorkshire English coal coked in five-oven battery at Chicago in 11 hours.

the location of the horizontal flue is an appreciable percentage of the total coke made. This condition is tolerable, particularly when the ovens are pushed without waiting until the upper part is thoroughly coked, and such coking operations with these ovens have given very good blast-furnace results. These ovens have an average capacity of about 18 to 19 net tons of coal per 24 hours.

It will be interesting to note the results of an investigation of the heat progression in the coking charge in an oven that was designed for 17 hours' operation, but operated between 23 and 24 hours. Such tests were made at the Seaboard Byproduct Coke Co.'s plant by inserting thermocouples in the coal charge in the same way as in the tests described before. The test disclosed that on that coking time the lower part of the oven coked decidedly faster than the part below the horizontal flue. When the lower part of the coke reached the temperature of 1,890 deg. F. the part below the horizontal flue had a temperature of only 1,450 deg. F. These temperature differences could, of course, be expected, because when operating on a longer coking time the quantity of gas per flue becomes correspondingly less and combustion is relatively quicker, thus causing a quicker progression of the coking in the lower part as compared with the upper part of the oven.

As far back as 1914 Dr. Koppers proposed, as a means of evening out temperatures within the heating system of coke ovens, the addition of waste gases to the air required in order to retard the combustion of gases in the heating flues because of the reduced content of oxygen in the waste gases and air mixture and thus lengthening the flame, resulting in an improved heat distribution and temperature progression within the coal charge. This process was tried out at Seaboard and Fig. 7 shows the result of the addition of waste gas till the mixture of waste gas and air contained 12 per cent oxygen. The waste gas was taken from the stack by means of a fan and blown into the air boxes on the regenerators, while the air was drawn in according to the regular practice.

This test was carried on for several weeks and it was shown that when the fan was taken off the temperature went back to the original ones as mentioned before. This test proves that the return of waste gases in ovens which have unequal heating conditions from bottom to top will greatly help the distribution of heat progression in the coking charge. It is a good cure for ovens which suffer from hot bottoms, as it causes a condition in the heating flues which is similar to that existing when using blast-furnace or producer gas. Blast-furnace and producer gas are most excellent fuels for heating the ovens, because such gases have a slower combustion speed and distribute the heats very uniformly.

How Capacity Effects Design

It is the belief of the majority of coke-oven and blast-furnace operators that, especially from high-volatile coals, better coke can be made in narrower ovens. In making the oven narrower, the coking capacity per 24 hours would necessarily be reduced unless a considerable multiplication of the operations would be resorted to. The first thought would naturally be to compensate for this by building higher and longer ovens and thus increasing the tonnage per oven per 24 hours. This would mean that the horizontal flue, with the type of oven as mentioned before, would have to be enlarged and thus occupy a larger space in the coking region, thereby retarding the coking of a proportionately larger amount of coal in that region. Furthermore, when equipping ovens so that they can be heated in the future with producer or blast-furnace gas, this flue must

be enlarged again in order to make it carry the additional amount of inerts present in such low B.t.u. gases.

It therefore was apparent that the oven as it stood should not be increased in capacity without making changes in the design eliminating the effect of the horizontal flue on the heating conditions and thus eliminating its effect on the quality of coke produced. Also with increased capacities a relatively smaller horizontal flue would require an exaggerated closing of the discharge openings of the vertical flues to such an extent that the drop of pressure through the reduced openings would become too high for the best draft conditions throughout the oven structure.

It might be thought best by some to design ovens without any horizontal flues. Such ovens without horizontal flues usually operate in such a manner that adjacent vertical flues serve alternately as up-burning flame flues and down-going waste gas flues and vice versa. It is evident, however, that an oven in which all adjacent heating flues or at least a large group of them serve at the same time in their entirety as up-burning flame flues or in their entirety as down-going waste heat flues is not subject to the danger of different draft conditions between adjoining flues.

Furthermore, the arrangement of the gas-supply flues in an oven in which the gas is burned up in one flue and down the next adjoining one is usually such that this gas-supply flue is paralleled by an up-going regenerator on the one side and a down-going regenerator on the other side. This arrangement greatly increases the difficulty of keeping the gas-supply flues tight. Also all ovens should be built so that producer gas or blast-furnace gas could be used advantageously in the future, and in up- and down-flow flue ovens there will always be a counter-current between waste gas and gas in regenerators, as well as between adjacent flues.

The New Koppers Combination Oven

These leading principles in oven construction have been tried out by the Koppers Co. in a battery of five ovens at the plant of the Chicago Byproduct Coke Co. at Chicago. The five ovens were put into operation on Feb. 1, 1922, and have since that time operated continuously on a great variety of coals at coking times between 10 and 12 hours. Fig. 8 shows the coke side of this battery. Fig. 9 shows the pusher side, and Fig. 10 shows the location of this battery in connection with the rest of the ovens. The new oven has a length of 37 ft. between doors, a height of chamber of 11 ft. 8 in. and an average width of 14 in., the taper between coke side and pusher side being 1½ in. Cast-iron jambs are used at the ends of the ovens. Fig. 11 shows the general design of the new type oven.

Heating in the New Oven

This shows that in this new design one side of the coke oven is heated in its entirety—that is, gas burns simultaneously on the coke side and on the pusher side —the products of combustion then join in the respective horizontal flues, pass through the crossover flues, one of which is located on the coke side and the other on the pusher side. Thence the products of combustion enter the respective horizontal flues of the adjacent heating wall and pass downward throughout the entire wall into the respective regenerators.

It is evident that the cross-sectional area of a horizontal flue when operating in such a way as described above can be considerably reduced as compared with the horizontal flue in ovens of the former design. This permits us to locate the horizontal flue higher than was previously possible and it furthermore permits the use of heavy walls between the horizontal flue and the coal chamber. This gives sufficient space to use insulating material if necessary in order to prevent any overheating of the gas space in the oven chamber.

One of the most important achievements claimed for this new design is the fact that the height of the flame flues has been considerably increased and these now extend as far up toward the top of the coal charge as is necessary for uniform heating of the entire charge. Thus the interference of the horizontal flue with the flame flue heating has been entirely eliminated. Of course the number of crossover flues could be increased beyond two preferably to five, the crossovers passing through the available spaces between charging holes. The size of the horizontal flue would thus of course be still more reduced, without causing an additional pressure drop.

It is clearly shown that with this new design the size of an oven has become independent of areas required for the former horizontal flue which interfered with the perfect operation of the ovens, especially when they were of great capacity, since it is important to retain the advantageous functions of horizontal flues.

Other Features of This Oven

It should be emphasized that on account of the fact that an entire side of a coke-oven chamber serves either for up-flow combustion or down-flow products of combustion, any leakage between individual flues becomes of little consequence, because all the gases flow either up or down and each flue is operating under the same pressure conditions. Since there is absolutely no counter-flow in any of the heating flues, it undoubtedly constitutes the safest construction for flame-heated coke ovens.

It will also be noticed that the regenerators reverse longitudinally with the battery instead of crosswise as used in the former design. The usual longitudinal taper of a coke oven requires that larger amounts of fuel gas are used on the coke side as compared with the pusher side. In the type of oven formerly built, products of combustion from the coke side of the oven chamber exchange their heat with the air or air and gas going up to the narrow pusher side. Since for the latter side gases are required in smaller volume, the efficiency of the heat exchange varies with reversals, as is shown by fluctuations in the stack flue temperature. In this new construction the in-going gases for each half of the oven are regenerated with the products of combustion from that half, and it is thus possible to maintain a lower uniform stack temperature which is the nearest practicable approach to the theoretical.

Flow of Gas in New Oven

The four drawings, Figs. 12, 13, 14 and 15, show the flow of gases when using coke-oven gas and blast-furnace or producer gas. Figs. 14 and 15 show the oven when operating on producer or blast-furnace gas. When producer gas or blast-furnace gas of low heating value is used for heating the ovens, it must be preheated in order to obtain the desired temperature and to operate economically. This preheating is accomplished by passing the gas through separate regenerating chambers on its way to the heating walls. In the new design of oven the arrangement of regenerators and flow of gases

is such that there does not exist at any time a counter-flow between incoming fuel gas and outgoing products of combustion in adjacent regenerator chambers. Fuel gas and outgoing products of combustion are always separated by a regenerator containing ingoing air. Should there be a slight leakage into the waste gas regenerator chambers, it would only result in loss of air, while it would be impossible to lose producer or blast-furnace gas.

Results Obtained From Test Battery

The battery of five ovens of this new design at Chicago was operated on 11 hours' coking time for several months with producer gas having a heating value purposely varied between from 85 to 125 B.t.u., and it was demonstrated that the oven when heated with this producer gas gave most satisfactory result as to heat distribution and fuel consumption. It was absolutely evident that there was no leakage of producer gas into waste gas on account of producer gas and air flowing in parallel and a counter-flow only existing between air and waste gas.

It has been demonstrated that on the five ovens at Chicago the arrangement of adjustable ports (Fig. 16) in that construction is correct for both conditions—that is, when using straight coke-oven gas or producer gas. The same small temperature difference between top and bottom when using coke-oven gas was observed as when using producer gas.

The tests for determining the progression of coking at different elevations in the oven chamber as made at the Providence plant were repeated with the same instruments and in the same manner on these five ovens at Chicago, and the results obtained were most gratifying. (See Fig. 17.) The absence of the interference of the horizontal flue, together with the unique design of adjustable air ports, gave a distribution of heat in such a way that the entire mass from top to bottom and from end to end was finished at the same time, the difference in temperature usually not exceeding 100 deg. F.

Coke Produced From New Ovens

The coke produced from these new type ovens was decidedly more uniform than that produced from the older ovens. The large pieces of coke originating near the horizontal flue region of the older oven were entirely absent in the coke from the new oven, and the coke from the bottom part of the new oven was just as large as the coke from any other part of the oven.

Shatter tests and combustion tests have been made from coke out of different elevations of the new ovens, and it has been found that the combustibility of the coke from the lower part of the ovens is the same as that taken from the upper part of the ovens. It was further shown that the shatter tests from the upper part of the oven are virtually the same as the shatter tests from the coke produced in the lower part of the oven.

In making coke of 11 hours in this new design of oven, the temperature of the flue walls did not exceed the maximum of 2,550 deg. F. and the fuel consumption in coking Pittsburgh coals was equivalent to 1,050 B.t.u. per pound of coal.

Advantages Claimed for New Oven

1. Greatest simplicity of design.
2. Perfect distribution of heat in such a way that the coking within the coal charge progresses uniformly at all places, thus preventing any over and under coking.
3. Increased capacity per oven unit.
4. Lowest fuel gas consumption.
5. Maximum strength of oven walls.
6. Lowest pressure differentials throughout the entire oven system.
7. Complete absence of counter-flow between flame flues and gas supply flues and gas regenerators.

All of the above-mentioned improvements will guarantee the long life of the oven structure and the continuous supply of most uniform coke at the lowest fuel consumption and operating expense. The low draft conditions existing in these ovens is of great importance, because it insures long life of the ovens.

Deductions From Operation of New Ovens

The foregoing shows that the coking of coal can be done in the most uniform manner, and the only matter to be decided upon in individual cases would be the width of oven that would be proper for certain coals to produce the best blast-furnace coke in respect to size of coke and its properties as to combustibility. Furthermore, at what temperatures or in length of time should coals be coked to produce the coke that gives the best blast-furnace results. From all observations made so far it seems to be correct for straight high-volatile coals to build the ovens as narrow as is practical, because this produces a coke of less fingery structure and cross-fracture than when made in wider ovens.

There is usually a variation in the coke starting with the wall side and ending at the center of the oven. This variation is greater in wider ovens than in the case of coke made in narrow ovens. In making tests of a piece of coke and taking samples from the inner end of the coke, the middle and the outer end of the coke, it has been observed that the specific gravity and porosity of the coke changes from center to end and that in wider ovens the cauliflower and dense end penetrates to a greater depth than in narrower ovens. It has been observed in the coke made in the five-oven battery at Chicago that a much more uniform porosity was practically maintained from one end to the other of a piece of coke.

Coals coked in narrow ovens give a higher yield of tar than when coked in wide ovens, indicating that the smaller yield of tar must have been accompanied by formation of additional gas and residue of carbon which is deposited on the cell walls of the coke. However, carbon coke made from tars is very refractory and combustion tests on carbon coke made from tar subjected to a temperature corresponding to that of coking operation—that is, about 1,800 deg. F.—showed that the combustibility of such material was decidedly less than the combustibility of ordinary coke. This would again indicate that a given coal when coked under conditions which yield the maximum in tar would produce a coke of greater combustibility than when coked under conditions where the tar yield is relatively low.

Author's Note—Figure 18 shows a photograph of coke on the coke wharf at the Chicago Byproduct Coke Co. made from Black Briar Illinois coal, such as is coked at a plant in the Mississippi Valley. Much has been said about a mysterious way of coking so-called non-coking Illinois coals at this plant. The coals which have been coked there and which have been called non-coking are in fact coking coals without any mystery whatsoever about them, and such coals have been coked in the oven described in this paper in 12 hours' coking time. Furthermore, thousands of tons of such coal have been coked at several other plants of Koppers ovens. (See Bureau of Mines Technologic Paper 137, by R. S. McBride and W. A. Selvig, Nov. 17, 1919.)

The Properties of Cold-Worked Metals

Properties of Cold-Worked Metals Explained by a Series of Postulates Regarding Conditions at Slip Planes—General Theory Checked by Experiments on Copper, Nickel, Iron, Molybdenum and Tungsten

By Zay Jeffries and R. S. Archer

MOST metals are hardened by working at ordinary temperatures. Tin and lead anneal rather quickly, so that a quick test is required to detect much hardening. Zinc also anneals at room temperature, but more slowly, so that considerable temporary hardening can be produced. The tensile strength of the ordinary metals like iron, copper and aluminum is increased from two to three times by commercial cold-working processes. The plasticity of a metal has probably never been exhausted by cold-working, since with sufficient care an almost unlimited amount of work may be carried out. Copper can be cold-rolled from a slab 1½ in. thick to sheet having a thickness of 0.002 in. Copper can also be easily cold-drawn until its length has been increased 5,000 times. Tungsten has been extended 200,000 times in length by drawing below its recrystallization temperature. By this it is not to be understood that extremely high reductions by cold-working are always practicable or desirable, but merely that they are possible.

Hardening by Cold-Work

While the general effects of cold-working are an increase in hardness and loss of plasticity, various specific properties are affected in somewhat different ways. As noted in a previous article,[1] when discussing overstrain, the elastic limit of iron is lowered sometimes to zero by cold-working, but is restored by aging or heating at low temperatures to a value which may be much higher than its original value. It has also been shown that the elastic limit of cold-worked brass may be raised from 22,400 lb. per sq.in. to 44,800 lb. per sq.in. by low-temperature heating. There is a lack of exact information regarding the effect of cold-working and aging on the elastic properties of other metals. Beilby[2] tested the elasticity of metals by making reed vibrators of them and observing the pitch and intensity of the notes produced. He found that cold-worked copper, silver and gold gave notes of greater intensity (i.e., had a greater amplitude of vibration) but lower pitch (lower frequency of vibration) than when annealed. This indicates that the cold-worked metals are less perfectly elastic than the annealed metals or have a slightly lower modulus of elasticity, but that they are elastic or nearly so up to much higher stresses.

The yield point is probably affected by cold-working more than any other property of the hardness group. While the tensile strength of iron (in wire) is raised from 48,000 lb. per sq.in. to 125,000, the yield point is raised from about 25,000 lb. per sq.in. up to a value practically identical with the tensile strength. Similar results are obtained with other metals, the ratio of yield point to tensile strength increasing markedly as cold-working progresses.

Figures are often given, particularly in handbooks, indicating that the elastic modulus is greater in the cold-worked than in the annealed condition. Such results are reported especially for the softer metals and alloys like copper and brass, whose true elastic limits are quite low when in the annealed condition. The lower moduli reported for the annealed metals were probably calculated from stresses which exceeded the true elastic limit. If there is any real difference in modulus, that of the annealed metal is probably the greater.

The hardening effect of cold-work is indicated to somewhat different degrees by the various tests for hardness. The scleroscope shows the greatest effect, followed by the Brinell test, while the sclerometer (indicating scratch hardness) shows little difference between cold-worked and annealed metal.

Resistance to repeated stresses is increased by cold-working. This is particularly noticeable in the softer metals, which can be used for springs when cold-worked, a service for which they are entirely unsuited when in the annealed condition.

The effects of cold-working are directional.[3] The increase in elastic limit and yield point are greatest in the direction of working, and there may even be a decrease in elastic limit under forces applied in the opposite direction. Cold-rolled or cold-drawn metals are generally used in such a way that the service stresses are in the same direction as the working stresses.

Elongation is reduced by cold-working. After very severe working the elongation before rupture is almost entirely elastic. The per cent reduction of area is also decreased by cold-working, but to a less marked extent than is the elongation. The reduction of area of a cold-worked metal may even be greater than that of annealed metal of large grain size. For example, a copper rod reduced by cold-swaging from ½-in. diameter to 0.10-in. diameter had a rather high reduction of area. After annealing at 700 deg. C., the reduction of area was somewhat less.

The hardening effect of a small or moderate deformation is greater the smaller the grain size of the metal subjected to such deformation. The strength obtainable by severe cold-working is about the same regardless of the initial grain size, so that a coarse-grained metal which originally has a lower strength than a fine-grained metal must be regarded as possessing greater capacity for hardening by cold-work.

In general the increase in hardness and loss in plasticity are continuous with increasing amounts of cold-work. The rate of change tends to decrease as the amount of work becomes large.

For instance, a discontinuity in the effect of cold-work on the properties of copper has been reported by Alkins.[4]

[1] "Overstrain, Internal Stresses and Creep," *Chem. & Met. Eng.*, vol. 27, No. 17, p. 833, Oct. 25, 1922.

[2] "The Hard and Soft States in Metals," G. T. Beilby, *J. Inst. Metals*, 1911, No. II, p. 5. For a complete account of Beilby's work, see his more recent book, "Aggregation and Flow in Solids," MacMillan, 1921.

[3] "The Effects of Cold-Working on the Elastic Properties of Steel," by J. A. Van den Broek, *Carnegie Scholarship Memoirs*, Iron and Steel Institute, vol. 9; also see *Engineering*, July, 1918.

[4] "The Effect of Progressive Cold-Work Upon the Tensile Properties of Pure Copper," W. E. Alkins, *J. Inst. Metals*, No. II, 1918, vol. 20, p. 33.

He found that when copper was reduced by wire drawing, a stage was reached at which a reduction of area of almost 10 per cent was accompanied by no change in tensile strength. This occurred when the diameter had been reduced from 0.553 in. to 0.373 in. in four successive passes. The tensile strength at this stage was about 52,000 lb. per sq.in. He also reported that wires which had been reduced less than this amount and which had a tensile strength less than 52,000 lb. per sq.in. were stable at ordinary temperatures, whereas wires which had been reduced a greater amount and which shortly after drawing possessed higher tensile strength were in an unstable condition and underwent a gradual reduction in strength at ordinary temperatures. The interruption in the hardening process on continued cold-drawing is probably attributable to spontaneous annealing.

After a metal has been severely cold-worked, further cold-working may cause a decrease in tensile strength. This is the result obtained when wires are "overdrawn." It is usually due to internal failures, such as splitting or drawing hollow. Strength normally increases as cold-working progresses as long as complete continuity of the metal is maintained. If the temperature of working is sufficiently close to the temperature of recrystallization, severe working may cause some annealing.

Commercial Terms for Hardened Metal

Commercially, metals are supplied in various degrees of hardness according to the purposes for which they are to be used. The various grades are designated by such terms as soft or annealed, medium or half-hard, and hard. A specially hard grade of brass is denoted by the term "spring temper." Aluminum sheet is supplied in various tempers designated by numbers which indicate the amount of reduction by cold-rolling subsequent to annealing. When it is desired to produce a finished article by some cold-working operation such as spinning or pressing and to have a certain degree of hardness in this finished article, sheet is selected of such temper that when subjected to the further deformation of the fabricating process it will have the desired final hardness.

The amount of cold-working which is necessary to produce material of any particular hardness is different for different metals. Copper wire is obtained in the half-hard condition by a reduction in section of about 60 per cent. A reduction in section of about 90 per cent is required to produce hard wire. These figures are typical of a pure metal of great plasticity. Less plastic metals and alloys such as brass harden more rapidly.

In general, the hardening effect of a given deformation is greater the lower the temperature at which deformation is effected. This is illustrated by some tests reported by Beilby.[2] Some gold wire was drawn at room temperature so that its length increased from 186 mm. to 352 mm. It was then drawn part way through a final die at room temperature, the remainder of the wire being drawn through the die at a temperature of approximately —80 deg. C. In this final pass the length of the wire was increased 32 mm., making the total length 384 mm.; therefore the total extension of the wire from the soft condition was then 106 per cent.

The tensile strength of the wire which had been drawn entirely at room temperature was 32,368 lb. per sq.in., whereas the tensile strength of the wire which was finished at —80 deg. C. was 35,213 lb. per sq.in. The wire drawn at the low temperature was thus 8.8 per cent stronger than the wire drawn completely at room temperature. Some copper wire treated in the same way showed a tensile strength of 60,928 lb. per sq.in. for the wire drawn entirely at room temperature and 64,960 for the part finished at —80 deg., an increase of 6.6 per cent.

The fact that iron is hardened much more by working in the blue heat range than at certain lower temperatures has been referred to in the former article[1] on "Overstrain, Internal Stresses and Creep," and it has been indicated that this behavior may be a general property of metals, although it is found to an exceptional extent in iron.

With the exception of tungsten and molybdenum, metals are usually worked either above their recrystallization temperatures or at room temperature—that is to say, intermediate temperatures are not intentionally selected for working and probably in no case is an artificially low temperature intentionally used. Work is often applied at temperatures between the recrystallization temperature and room temperature, however, in the natural sequence of operations. Thus ingots of copper or aluminum may be started through the rolls hot—that is, above the temperature of recrystallization —and rolling may be continued while the metal cools down gradually to room temperature. On the other hand, the heat produced by cold deformation itself may raise the temperature of a metal somewhat above the assumed working temperature. It has been estimated that in drawing copper wire presumably at a temperature of about 20 deg. C. the actual temperature may be about 75 deg. C.

Variations in the conditions of cold-working are unlimited in respect to such factors as the stages of reduction, the speed of drawing or rolling and the shape of dies or rolls. Variations in such factors produce slight variations in the properties of the metals, because of uneven distribution of the deformation, or of temperature and time effects. For practical purposes, however, the properties of a cold-worked metal are nearly independent of the manner of deformation.

Cold-Worked Metal at Elevated Temperatures

The properties of cold-worked metals vary with temperature in much the same way as do their properties in the annealed condition. Hardness decreases with rising temperature. Tensile strength decreases with rising temperature throughout the intermediate zone of temperature, but also decreases on cooling into the low temperature region of brittleness. Thus cold-drawn tungsten wire—like annealed tungsten wire—is weaker at liquid air temperature than at room temperature. No other metal so far tested is weaker at the temperature of liquid air (—185 deg. C.) than at room temperature, but most metals probably become weaker at some temperature lower still.

The elongation of cold-drawn wires likewise follows the same general trend as that of annealed wires. As the temperature rises from the cold brittle region, the elongation increases to a maximum value, and then, on further rise of temperature, decreases. The temperature of maximum elongation, however, is lower for cold-worked metal than for annealed metal, at least for those metals whose loss of ductility at low temperatures is due to grain boundary brittleness. It is in accordance with this law that cold-drawn tungsten wire is ductile at room temperature, whereas recrystallized tungsten wire is brittle. At temperatures above that of recrystallization, the effects of cold-working are lost, and the

properties become those of annealed metal, depending upon the grain size established by the conditions of deformation and heating.

When there is a discontinuity in the effect of temperature on the mechanical properties of a metal in the annealed condition, a corresponding discontinuity is found in the properties of the cold-worked metal. For example, the blue heat properties of annealed iron are also found in cold-worked iron, but are less evident as the amount of cold-working increases.

Cold-worked metals are nearly completely annealed or softened by heating under conditions of time and temperature that produce general visible recrystallization. Some softening may occur at much lower temperatures. It has already been mentioned[1] that iron which has been severely cold-worked and aged is softened somewhat by heating at 100 deg. C., although visible recrystallization occurs only above 450 deg. C., and that hard copper wire loses some of its strength slowly at room temperature. It has also come to the authors' attention that springs which depend for their elasticity on hardness produced by cold-work gradually deteriorate to some extent at ordinary temperatures so that they become unfit for certain uses.

Summary of Properties

The following general statements may be made regarding the properties of cold-worked metals:

1. Hardness and strength of a metal increase with the amount of reduction by cold-work until internal failure is produced.

2. Plasticity of a metal decreases as the amount of cold-work increases.

3. With change in temperature of test, the properties of a cold-worked metal follow those of annealed metal, any discontinuities in the properties of annealed metal being reflected in those of cold-worked metal.

4. The effect of a given deformation is greater the lower the temperature at which it is effected, except that in some metals abnormally large effects are produced in a certain region of temperature, corresponding to the blue heat in iron.

5. Elongation of a cold-worked metal increases with respect to the elongation of annealed metal, as the temperature of test decreases below the working temperature, reaching a maximum value, after which further decrease in temperature produces a rapid decrease in elongation.

6. Elongation of a cold-worked metal decreases with respect to the elongation of annealed metal as the temperature of test is raised above the working temperature until the recrystallization temperature is reached, when elongation is increased by annealing.

7. Temperatures of maximum elongation are different for various metals.

8. For any given metal, the temperature of maximum elongation is lower the greater the amount of cold-work, and is in general lower in cold-worked metal than in annealed metal.

9. In metals which become brittle on cooling because of intercrystalline weakness, the cold-worked metal may possess considerable elongation at temperatures at which the equi-axed metal is brittle.

10. The greater the amount of cold-work the less is the elongation at the temperature of working or at the temperature of maximum elongation on cooling.

11. The hardening effects of slight or moderate deformations are greater the smaller the initial grain size of the metal.

12. Reduction of area of a cold-worked metal is in general less than in the annealed state.

Conditions at Slip Planes

The properties of cold-worked metals and the phenomena of plastic deformation indicate that important changes may take place on the surfaces of slip during and after deformation. A number of propositions regarding the conditions at slip planes are herewith presented. For the purposes of this discussion, the term "slip plane strength" will be used to denote the resistance to motion along a slip plane after slip has started. "Crystal strength" means the shearing strength of the unbroken crystal on planes parallel to the slip plane under consideration; it is the resistance to motion on the slip plane, *before* slip starts.

(1) *Immediately after slip begins, the slip plane strength is less than the crystal strength.* In coarse grained metals, slips are readily observed which have extended for a distance of several thousand atom diameters. In single crystals tested in tension the extent of the motion on individual slip planes is still greater. After slip has once started, therefore, the resistance to further motion on the same plane must, for a while, be less than the resistance to the starting of slip on a parallel plane and hence less than the original shearing strength of the crystal. When iron has been recently

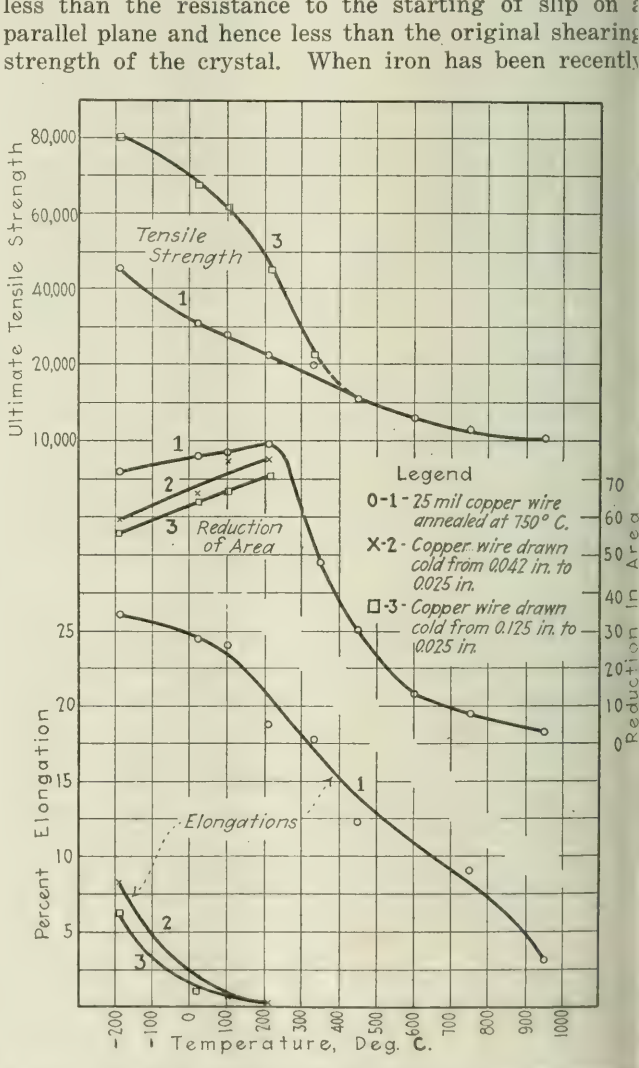

FIG. 1—TENSILE STRENGTH, ELONGATION AND REDUCTION OF AREA OF ANNEALED AND COLD-DRAWN COPPER WIRES AT VARIOUS TEMPERATURES. (JEFFRIES)

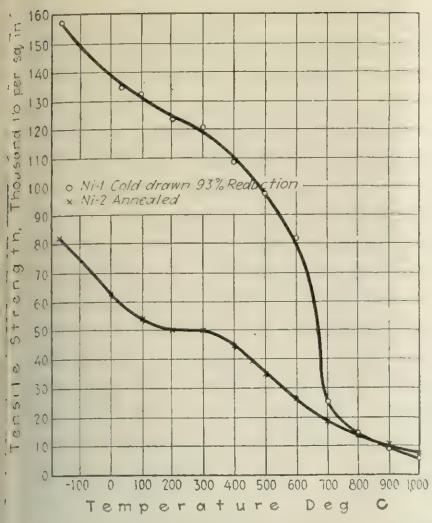

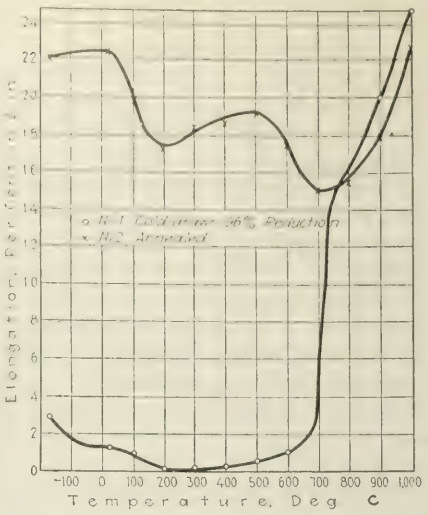

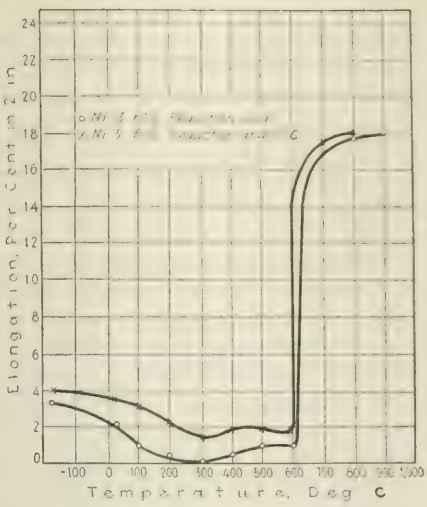

FIGS. 2, 3 AND 4—PROPERTIES OF NICKEL WIRE AT VARIOUS TEMPERATURES (SYKES)
Fig. 2—Tensile Strength Fig. 3—Elongation Fig. 4—Elongation, Cold- and Hot-Drawn

overstrained, the application of very small stresses results in permanent deformation which must take place by motion on the slip planes formed in the first overstraining process. Resistance to motion on these planes must, therefore, be quite low as compared with their original strength. The same is true of brass or other metals whose elastic limit is decreased by overstraining.

(2) *As slip continues, the slip plane strength increases to a value which may be greater than the crystal strength.* It is a striking fact that when single ductile crystals are tested in tension, failure does not occur on the first slip plane. Motion continues for a certain distance, after which further deformation takes place by slip on other planes. This means that the resistance to motion on the original slip plane must have increased to a value somewhat greater than the resistance to motion on parallel planes in the crystal. The process of slip may be termed "self-stopping."

(3) *In a metal composed of an aggregate of grains, slip is stopped partly by the interference of adjacent grains and partly by the resistance on the slip plane itself.* In a single crystal which is ductile it is necessary that motion continue on the first slip plane until the resistance to motion automatically becomes greater than that in the unbroken crystal. In an aggregate composed of many grains, however, motion on a slip plane in any one grain is opposed by adjacent grains through which there are no corresponding planes of weakness. Slip may there be brought to a halt by end resistance before sufficient motion has taken place to increase the resistance on the plane to the self-stopping point.

(4) *Slip planes in all stages of their history are present in cold-worked metals.* Since the slip plane strength increases with motion along the plane and since the extent of the motion on the various slip planes is different according to the various conditions of external support, it is evident that the resistance to motion on the various slip planes after deformation stops may be anything from the minimum to the maximum obtainable.

(5) *Slip causes rupture of the atomic bonds on the slip plane, and immediately after motion has stopped there is only partial re-establishment of cohesion.*

(6) *When the registry of the displaced crystal fragments permits, cohesion is re-established by the fragments joining into larger crystalline units.* The slip plane then disappears as such, being replaced by a *potential* slip plane whose strength is equal to the crystal strength.

(7) *As a rule, the crystal fragments do not register after deformation, and all degrees of disregistry occur.* It has been shown by X-ray analysis that new orientations are created by plastic deformation. Consequently there must be many, probably a large majority, of crystal fragments whose orientation does not permit them to unite except by the process of grain growth.

(8) *Re-establishment of cohesion between crystal fragments of different orientations must be attended with various degrees of disorganization as regards the arrangement of the atoms at the slip plane.*

(9) *This metal of partly disorganized structure simulates an amorphous material in its mechanical properties.* The characteristic properties of typical amorphous materials are first the great influence of time upon deformation, and second, the rapid change in properties with change in temperature. Cold-worked metals behave as though the resistance to motion on the slip planes varies in a similar manner with time and temperature. The slip plane strength increases on cooling and decreases on heating at a more rapid rate than does the crystal strength. For example, the tensile strength of cold-worked iron increases on cooling much more rapidly than the tensile strength of annealed iron.

(10) *Atomic rearrangement on slip planes takes place at temperatures much lower than are usually associated with recrystallization.* During the spontaneous aging of overstrained iron at ordinary temperature, or the rapid recovery of elasticity at a blue heat, the slip plane strength increases so that small stresses no longer produce permanent deformations. This increase in slip plane strength, or "healing" as we may call it, may consist in the growing together of fragments of sufficiently similar orientation, or in the establishment of cohesion at additional places on the planes between fragments that do not register. Rosenhain has observed that when a piece of iron is polished immediately after overstrain, lines are found which probably represent the intersection of the polished plane of the specimen with the surfaces of slip. These lines (called X-bands by Howe) are not found in the specimen if permitted to rest or recover before polishing. Lea has reported

that the recovery of iron or mild steel from overstrain is accompanied by an *increase* in density. All evidence is to the effect that the healing process involves an increase in the continuity of the metal. Although the electrical conductivity of metals is decreased by cold-working and is in general least when the metal is in its hardest condition, it is to be expected that the hardening of a cold-worked metal like iron by aging or heating at low temperatures would be accompanied by an *increase* in conductivity. Further heating would produce a continued increase in conductivity but eventually a decrease in hardness.

(11) *At certain temperatures slip planes may heal during deformation.* This is what happens at a blue heat in iron and at similar temperatures in nickel. When the slip plane strength exceeds the crystal strength, deformation is forced to take place on new slip planes. Spontaneous healing during deformation therefore results in a more intricate system of internal deformation.

(12) *On lowering the temperature, the slip plane strength may increase to a value greater than the crystal strength without any healing taking place.* For a given degree of disorganization at the slip plane and a given degree of re-establishment of cohesion, the ratio of slip plane strength to crystal strength is greater the lower the temperature. Slip may therefore reach a self-stopping state at low temperatures after less motion than at higher temperatures. This would lead to greater internal working by a given external deformation at low temperatures than at high temperatures. This excess of slip plane strength over crystal strength at low temperatures is the fundamental cause of the general increase in elongation with decrease in temperature of test, and in particular of the fact that wires drawn at certain temperatures until their ductility is nearly exhausted regain ductility on cooling to lower temperatures. Elongation takes place after the yield point is passed. Yield point is a function largely of *crystal* strength, being the stress required to deform the crystal. After the yield point is passed, permanent deformation of the metal continues as long as the strength is sufficient to sustain the deforming load. Rupture finally takes place at the slip planes. An increase in slip plane strength as compared with crystal strength therefore raises the tensile strength as compared with the yield point, and hence promotes elongation before rupture.

(13) *The properties of the disorganized metal at the slip planes probably never become those of the hypothetical vitreous amorphous metal which would prevent any further motion on the same planes during further plastic deformation.* This has been discussed more fully in a previous article,[5] in which it was pointed out that slip planes must be used repeatedly to account for the large amounts of plastic deformation that are possible.

Cause of Strain Hardening

The motion of crystal fragments on a number of intersecting systems of slip planes destroys the continuity of the planes of weakness. Slip in any crystal fragment is opposed by adjacent fragments in somewhat the same way that slip is opposed at grain boundaries. During the first stages of deformation the orientations of the fragments produced from any one grain are only slightly changed and the effectiveness of the support by adjacent fragments is not so great as at the grain boundaries. As the deformation progresses, some of the crystal fragments are rotated, as is shown by the fact that new orientations are found. The slip interference is then comparable to that at grain boundaries and the structure is comparable to a very fine-grained structure.

Since the resistance to motion along a slip plane may be greater than in the unbroken crystal, these slip planes are sources of strength and hardness aside from the slip interference action. In this respect it may be said that the creation of disorganized structures whose properties simulate those of an amorphous material is a cause of hardness in cold-worked metals. However, the importance of such amorphous metal in hardening seems to have been greatly exaggerated.

The hardening effect of deformation increases with the number of slips taking place. Since strain-hardness is to be attributed chiefly to the slip interference created by the relative displacement of crystal fragments, this hardening will be greater, in general, the larger the number of planes on which slip takes place. A given external deformation will, therefore, produce greater hardness the greater the number of slip planes

[5] "The Amorphous Metal Hypothesis," by Zay Jeffries and R. S. Archer, *Chem. & Met. Eng.*, vol. 25, p. 697 (Oct. 12, 1921).

produced or the greater the internal working of the metal. In accordance with this principle, deformation produces hardness more rapidly as the temperature is lowered, as the initial grain size is smaller, and finally when spontaneous healing takes place during deformation (as in the blue heat range in iron). Fettweiss[6] states in his summary that cold-working of iron, followed by heating at a blue heat, produces the same results as working at a blue heat. The principle just stated shows, however, that a given deformation effected at a blue heat must produce more hardening than the same deformation effected at room temperature and followed by heating to a blue heat. A knowledge of the mechanism of the blue heat phenomenon thus assists in correlating its various manifestations.

Some Typical Examples

The examples to be given include metals crystallizing with face-centered and body-centered cubic lattices. No extensive investigations have been reported on metals crystallizing with hexagonal lattices, but such information as is available indicates a tendency toward less plasticity, a narrower range of temperature within which they are plastic and a tendency toward greater brittleness of the individual crystals than in cubic metals. The mechanical properties of the hexagonal metals are, however, in harmony with the general rules put forth in this article.

The data from which the accompanying curves were plotted are the results of tests made on wire of 0.025 in. diameter. In each case the elongation was measured on a length of 2 in. Testing conditions were similar for the various metals. For testing at low temperatures, a bath of liquid air was used; for tests at 100 deg. C., boiling water; and at slightly higher temperatures, a bath of oil. At still higher temperatures specimens were heated in an electric tube furnace, an atmosphere of argon being used to protect the specimens from oxidation when this was necessary. No determinations were made of elastic limit or yield point.

In Fig. 1 are two curves showing the variation in the tensile strength of annealed and cold-drawn copper with changing temperature. The curve for the cold-drawn wire is discontinued above 330 deg. C., because in this range of temperature the wire anneals rapidly and becomes practically identical with the material represented in the other curve. Below the recrystallization temperature the strength of the cold-worked wire increases more rapidly than the strength of the annealed wire.

Fig. 1 also shows the effect of temperature on the elongation of annealed copper wire and of two samples of cold-drawn wire reduced different amounts by drawing. Again the elongation of the cold-worked metal varies with temperature in the same manner as that of the annealed metal. At the lower temperatures the elongation of the cold-drawn wire increases more rapidly than that of the annealed wire, and the indications are that at some very low temperature the elongation of the cold-drawn wire might be the greater. Results are not plotted for temperatures above 200 deg. C. for the cold-drawn wires. Annealed and cold-drawn copper wires are also compared as to reduction of area in Fig. 1. The effect of temperature on this property is seen to be in the same general direction for cold-drawn and annealed wires. Again, results are not plotted above the recrystallization temperature.

Fig. 2 shows the effect of temperature on the tensile strength of annealed and cold-drawn nickel wire and records the same general tendency of decrease in strength with increase in temperature noted for copper. There is a marked break in the curve at 200 to 300 deg. C. for the annealed wire. This has been discussed above and is believed to be due to spontaneous healing of slip planes during deformation. The same discontinuity is reflected in the curve for the cold-drawn wire, but is less apparent. Annealing is seen to take place rapidly at 600 to 800 deg. C.

Elongation-temperature curves for the same nickel wires are shown in Fig. 3. Below the temperature of recrystallization annealed wire appears to have a general tendency toward increased elongation with decreasing temperature. This general trend is broken at 200 to 400 deg., the minimum in elongation at 200 deg. C. corresponding with the horizontal portion in the tensile strength curve. A slight drop in elongation on cooling from room temperature to the temperature of liquid air is probably due to the beginning of low-temperature brittleness. No tests were made between room temperature and liquid air temperature, and it is quite likely that at some intermediate temperature the elongation would be higher than at any point shown on the curve. Elongation of cold-drawn wire increases continuously as it is cooled from 200 deg. C. down to the temperature of liquid air. The fact that no drop in elongation at low temperatures is shown corresponds with the general observation that cold-drawn metals remain ductile at lower temperatures than annealed metals. The rise in elongation in the cold-drawn wire above 400 deg. C. is due to annealing.

Fig. 4 shows elongation-temperature curves for nickel wires reduced the same amount at room temperature and at 400 deg. C. respectively. It will be noted that

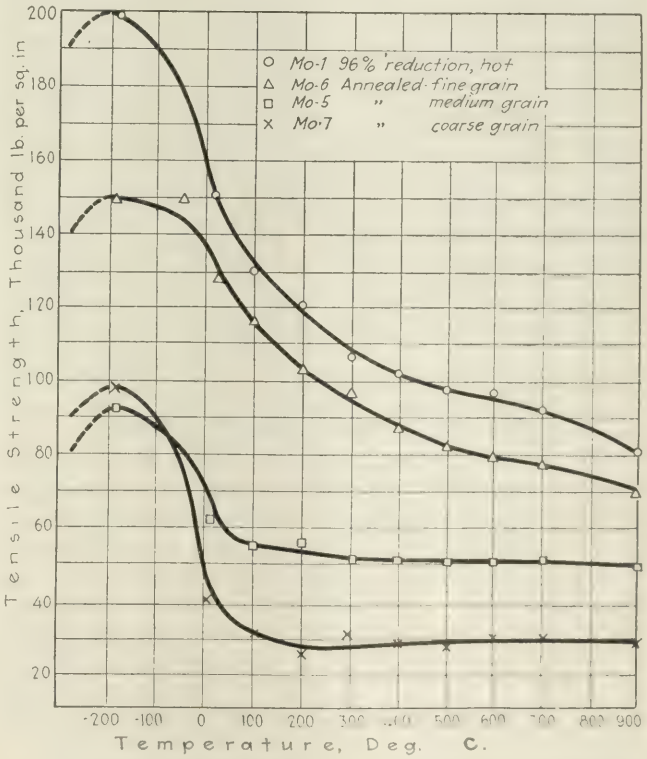

FIG. 6—TENSILE STRENGTH OF MOLYBDENUM WIRES AT VARIOUS TEMPERATURES (SYKES)

[6] "The Blue Brittleness and Aging of Iron," *Stahl und Eisen*, Jan. 2 and 9, 1919.

the elongation of the latter is higher, in accordance with the general rule that the effect of cold-work is greater the lower the temperature at which it is effected. These wires, which have been reduced less than the one represented in Fig. 3, show distinct minima in elongation at 300 deg. C., corresponding to the horizontal in the tensile strength curve for annealed nickel. In view of these curves it is probable that the minimum in elongation shown in Fig. 3 is also at least partly attributable to this blue heat phenomenon.

Fig. 5 shows the effect of temperature on the tensile strength of annealed and cold-drawn Armco iron wire. The strength increases with the amount of reduction by cold-drawing. There is a general decrease in tensile strength with increasing temperature, but annealed wire shows a very marked increase in strength on rising temperature, the strength reaching a maximum at about 200 deg. C. As pointed out above, the actual temperature of this maximum depends quite largely on the rate of testing. The same discontinuity is shown in the cold-drawn wires, but to a less marked extent. There is also a considerable increase in strength on raising the temperature of annealed wire between 850 and 930 deg. C., due to the allotropic change from alpha to gamma iron.

Elongation-temperature curves for annealed and cold-drawn iron wire are also shown in Fig. 5. Decrease in elongation of annealed wire at temperatures from 450 deg. C. upward is in accordance with the general law. A marked minimum in elongation at 100 deg. C. is due to the blue heat phenomenon. Below this temperature the elongation again rises in accordance with the general law to a maximum (which may be somewhat below room temperature), after which it decreases because of low-temperature brittleness. The cold-drawn wires also reflect the minimum in elongation in the blue heat range. Above about 450 deg. C. annealing takes place, after which the properties become similar to those of the annealed iron. There is no positive evidence here that the elongation of the cold-drawn wires would be greater than that of the annealed wire at very low temperatures, but such may be the case.

The same figure shows the effect of temperature on the reduction of area of annealed and cold-drawn iron wire. The general tendency is as usual—a rise in reduction of area with increasing temperature up to the recrystallization temperature, above which the reduction of area decreases. The minimum in reduction of area at about 330 deg. C. is again a manifestation of the blue heat phenomenon. It will be observed that the minima of elongation do not occur at the same temperatures nor at the same temperature as the maximum in the tensile strength, although the results are all from the same specimens. It is of interest that the cold-drawing has affected the reduction of area relatively less than the tensile strength and elongation.

Fig. 6 shows the effect of temperature on the tensile strength of annealed molybdenum wires of various grain sizes. (The wire described as reduced 96 per cent hot was produced by hot-swaging followed by drawing, part of the reduction at least being effected below the recrystallization temperature.) In all wires the tensile strength decreases with rising temperature throughout the range shown. In the annealed wires, particularly those of medium and coarse grain size, there is a marked horizontal extending from about 100 to 900 deg. C., which is approximately the recrystallization temperature of molybdenum. This may be a manifestation of the blue heat phenomenon. Although tests were not made below the temperature of liquid air, the strength is represented as decreasing at lower temperatures. This fall in tensile strength might be expected to occur at some temperature slightly lower than —185 deg. C., since the tensile strength of tungsten falls between 25 deg. C. and —185 deg. C. Curves have already been given and discussed showing the effect of temperature on the elongation of molybdenum, in Fig. 2 of an article entitled "Effect of Temperature, Pressure and Structure on the Mechanical Properties of Metal" (*Chem. & Met. Eng.*, vol. 27, No. 15 (Oct. 11, 1922).

Fig. 7 shows the effect of temperature on the tensile strength of two kinds of tungsten wire, of which No. 1 has a structure composed of unstrained but slightly elongated grains. Wire No. 2 was produced by swaging and drawing from 0.165 to 0.025 in. at temperatures gradually falling from 1,300 to 1,000 deg C. The temperatures covered by these curves are entirely below

recrystallization. The tensile strength increases on falling temperature, but is lower at —185 deg. C. than at room temperature. Tungsten is the only metal in which this drop has been observed, but, as mentioned above, it probably occurs in most metals at some very low temperature. The actual hardness of the tungsten is probably greater in liquid air than at room temperature and the decrease in strength is probably due to brittleness.

Fig. 7 also shows the effect of temperature on the elongation of three kinds of tungsten wire as described in the figure. In all cases the the elongation increases on falling temperatures until the region of low-temperature brittleness is reached. These curves illustrate particularly well the law that the maximum elongation occurs at lower temperatures the greater the amount of cold-working, but that the actual elongation at this maximum decreases as the amount of working increases. Comparing the elongation and tensile strength curves, it will be noted that the development of brittleness is at first accompanied by a sharp rise in tensile strength. This appears to be a rule for all metals.

In both wires shown the reduction of area increases with rising temperature throughout the temperature range given. At all temperatures covered by these tests the reduction of area is greater in the cold-drawn wire than in the annealed wire.

Legal Notes

By Wellington Gustin

Notation in Receipt Regarding Disputed Shortage Not Sufficient Notice of Loss

An interesting point on shipping claims is had in an action by the Calumet & Hecla Mining Co. against the Delaware, Lackawanna & Western R.R. Co. and decided for the defendant by the Appellate Division of the New York Supreme Court. (190 N.Y.S., 410.)

The Calumet company claimed the right to recover from the railroad company the sum of $666.91, the value of 10 billets of copper, being a part of a shipment of 524 billets, shipped by it from its works at Lake Linden, Mich. The initial carrier was the Mineral Range R.R. Co. The freight was prepaid to New York City, consigned to plaintiff. The defendant, being the final and delivering carrier, duly gave notice of the arrival of the copper in New York. The plaintiff then directed the defendant to deliver the shipment, together with other copper, totaling 2,543 billets, to the steamship Orleans, of the Oriental Navigation Co., at the port of New York, for transportation to Bordeaux, France. Delivery was made 10 billets short.

Defendant gave to plaintiff the steamship receipts for the copper actually delivered, and received from the plaintiff in exchange therefor a receipt which plaintiff claimed constituted a notice of loss or damage which entitled plaintiff to recover. The receipt describes fully the copper actually delivered on board, and then contains the following statement respecting the 10 billets which had been lost:

"Ten (10) billets, mkd. C & H, more, in dispute. If on board to be delivered."

The sole question in the case to be determined was whether the above words contained in the receipt constitute a sufficient notice in writing within the meaning of the clause of the bill of lading following:

"Claims for loss, damage or delay must be made in writing to the carrier at the point of delivery, or at the point of origin, within 4 months after delivery of the property, or in case of failure to make delivery, then within 4 months after a reasonable time for delivery has elapsed. Unless claims are so made the carrier shall not be liable."

Claim Not Filed Within Specified Time

Within a few days of the receipt letters were written by both parties regarding the shortage, and 2 months thereafter the Calumet company was notified that the shipment checked 10 billets short on arrival at Bordeaux. Eleven months thereafter it filed its claim against defendant for the loss.

Notation Did Not Constitute Notice of Loss, Says the Court

The court says the receipt executed by plaintiff and the subsequent letters disclose that some dispute had arisen respecting the 10 billets of copper claimed to be missing from plaintiff's shipment. The defendant, evidently thinking there might have been a mistake in checking the copper, wished to take advantage of a rechecking when the ship reached Bordeaux. When the shipment was so rechecked at Bordeaux it became certain that the 10 billets of copper had not been found on board, and the plaintiff was so notified. However, it took no further step to notify the defendant until this belated notice of claim was filed, says the court. The receipt as mentioned above was not intended to operate as a notice under the bill of lading, the court said. The use of the words "in dispute" contained in the receipt, as above, showed clearly that neither of the parties regarded the notice as final, or that it had actually been determined that any loss or damage had been sustained. At most, it indicated only uncertainty as to whether the 10 billets of copper were included in the shipment. Such uncertainty was to be resolved when the goods came to be rechecked on arrival at Bordeaux.

The court says the defendant carrier had a right to expect further advices if, upon arrival there, it was found that the 10 billets were missing, and, if the plaintiff was to make claim for loss, that the defendant would receive timely written notice of such claim. Having failed to make such claim within 4 months after delivery of the property in question, reliance could not be had on the receipt, as it did not constitute even a substantial compliance with the requirements of the bill of lading.

Slide Rule for Furnace Calculations

A handy circular slide rule for calculating furnace additions has been designed by F. Wright and is being distributed by the Pittsburgh Electric Furnace Corporation. It contains six scales—viz., for the weight of the furnace charge, the points of alloy or carbon to be added, the percentage of that element in the ferro available, the per cent of absorption by the bath, the melting loss, and finally the pounds of ferro required. Normally the slide rule would be used to determine the pounds of addition required to bring the bath to a given analysis, although it may obviously serve to compute any unknown factor, given the other five.

Internal Mixers*

A Critical Study of the Limits of Application of the Internal Mixer to Rubber Compounding—The Chief Difficulties in Its Use Are Analyzed—Where Possible Corrections in Design Are Suggested and the Limits to Its Use Defined

By R. P. Dinsmore
Chief Compounder, Goodyear Tire & Rubber Co.

IT IS intended to discuss the action of internal mixers (chiefly in comparison with mill mixing) on the basis of practical production experience in connection with various types of rubber compounds, especially tire stocks. Although most of our work was done on one type of mixer, sufficient data were obtained from other types to make our conclusions more or less general. Under internal mixers we may class all those which utilize a closed chamber to hold the charge or batch and which for mixing depend upon the action of a mixing mechanism which works the material back and forth laterally, longitudinally or both.

The internal mixer naturally appeals to the practical rubber man who has been accustomed to working his rubber on a mill by means of his hands and a knife and to putting his compound onto the rolls with a shovel, during which process he must inhale considerable dust and fumes. The idea of eliminating much of this labor and greatly reducing cost and fumes is attractive. Probably the advent of carbon black into the field of rubber compounding has done more than any other one thing to popularize the idea of internal mixing. Certain factors combined to make it more practicable to use the early design of internal mixer for mechanical goods stocks—that is, molded goods other than tires—rather than for tire stocks. Later improved designs and, as previously stated, the dirt nuisance from carbon black caused tire men to investigate its possibilities more carefully.

Classification of Rubber Stocks

Before discussing the behavior of various types of stocks it may be well to make a general classification for reference purposes. The rubber manufacturer roughly classifies his stocks as high grade and low grade, not upon the basis of the degree of satisfaction with which they perform the required functions in the finished article, but chiefly according to rubber content. Under high-grade stocks, therefore, we may class most tire compound, balloon stocks, and a few mechanical goods and so-called master batches which are simply mixtures of individual compounding ingredients with rubber, designed to facilitate handling or increase the accuracy of weighing. Low-grade stocks include most mechanical goods compounds, a few tire stocks such as bead fillers and in this group we may also class accessories.

Low-Grade Stocks Can Be Handled in Internal Mixers

Early experience with internal mixers showed that most low-grade stocks could be mixed successfully and many of them more economically than on a rubber mill. The reasons are fairly obvious in that where there is a great deal of dry filler compared to the amount of rubber present, and especially where softeners are used in considerable quantities, it is easier to keep the fillers in contact with the rubber and effect a mixture when the entire mass is inclosed and subjected to a stirring action than when the compound must be shoveled onto the mixing rolls. It is a matter of long experience in the rubber industry that many batches of this type can be best mixed on a mill by the addition of a great deal of softener and the use of a scraper to take the rubber off the rolls. In internal mixing much the same thing is done in a more efficient manner. It is true that if batches were made too soft they sometimes stuck in an internal mixer and made it difficult to clean out, but in general it may be said that low-grade stocks mixed fairly well.

In the initial stages of internal mixer development work was also done with master batches, particularly those containing carbon black, but sufficient trouble was experienced to prevent the old type of mixer becoming a serious competitor of the mill for this purpose, and in the case of carbon black, the bearings were attacked due to inability to pack them tightly enough to keep the black out.

Before we leave the early history of this type of mixer it may be well to state that it was found essential to take the large chunks of rubber stock coming from the mixer and pass them through mill rolls in order to sheet them out in a form which would be convenient for handling and storage and which would admit of sufficiently rapid cooling to prevent injury to the compound. This condition has remained constant throughout all subsequent developments. It was found that even with this expedient high-grade stocks other than master batches were very tough when mixed in this way and had a strong tendency to start premature vulcanization, or as we express it, to "scorch."

Improved Design of Internal Mixers

In the last few years improved types of internal mixers have been put on the market with better mechanical design and better facilities for cooling. Bearings have been perfected, the machine in general strengthened, and the mixing mechanism as well as the chamber has been water-cooled and the method of emptying the mixer has been made much more simple and effective. It may be pointed out here that the internal mixer differs essentially from the mill in that much less batch surface, in proportion, is in contact with the cooling walls. This makes effective cooling difficult and hence cooling methods are highly important.

Experiments With High-Grade Stocks

In an endeavor to find out what this type of mixer could do, something over 1,000 experiments were made, chiefly on high-grade stocks which were grouped under two headings, one being master batches, which in no case contained sulphur; and the other group being tire stocks, which, of course, always contain sulphur and usually an organic accelerator.

In view of our past experience we expected our best results from high-grade stocks would be obtained in

*Revision of a paper presented at the Birmingham meeting of the American Chemical Society, April 5, 1922.

mixing carbon black into rubber, providing the bearings were properly designed. Work was therefore commenced on this basis.

For purposes of this study, a batch with the approximate composition of 35 volumes of carbon black and 100 of rubber was used. It was found impracticable to go to a higher concentration of black, and although lower concentrations were tried and equally good results obtained, no particular benefit was noticeable. Due to our experience in mill mixing, which showed that better results are obtained from mixing small-size batches, we began with a 60-kg. batch, which about half filled the mixer, and gave the rubber a separate mastication of from 2 to 5 minutes, adding the carbon black and mixing to a total time of from 8 to 20 minutes.

Initial temperatures averaged around 50 deg. C. and final temperatures about 95 deg. It was impossible to get a smooth mix, and the batch was dusty when dumped, showing an incomplete incorporation of the filler and the rubber. Batch weights were gradually increased to 75 and 100 kg. without any appreciable improvement. The temperature varied a great deal due to difficulty in regulating the water feed to the cooling chambers. This difficulty was finally overcome, but the tendency of the batch seemed to be to break up into lumps rather than to mix in a uniform mass. Longer working of the rubber before the black was added improved this condition to some extent; however, lumping continued to result, apparently from moisture taken from the rubber and condensed on the walls of the mixing chamber. It was finally found advisable to give the rubber a preliminary working or breaking down on the mill before putting it in the mixer. With this expedient better results were obtained, and after changing the batch weight we mixed as follows: Broken-down rubber was used and worked in the mixer for 5 minutes, then the compound was fed in very gradually until it was all assimilated, giving a total mixing time of 25 minutes. A 60-in. mill was required to batch off, the final temperature of the batch being 142 deg. C. This stock appeared to be uniformly mixed, no lumps were apparent, but it was noticeable that the glossy appearance characteristic of this batch when mixed on a mill was lacking.

Material mixed in this way gave a very satisfactory quality when tested in the various compounds employing

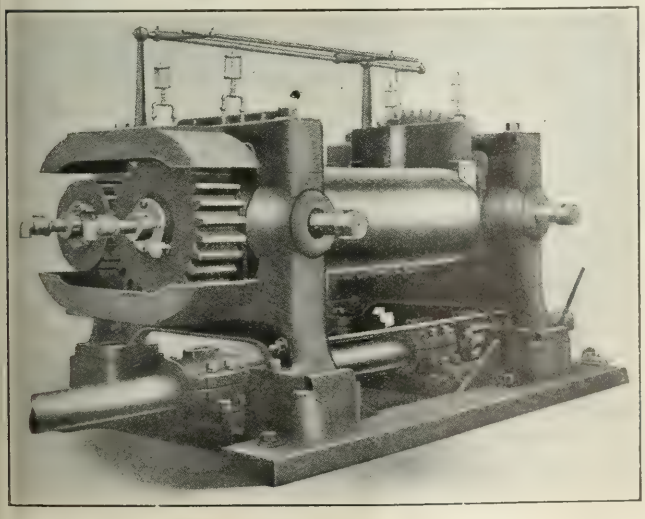

FIG. 1—STANDARD MIXING MILL

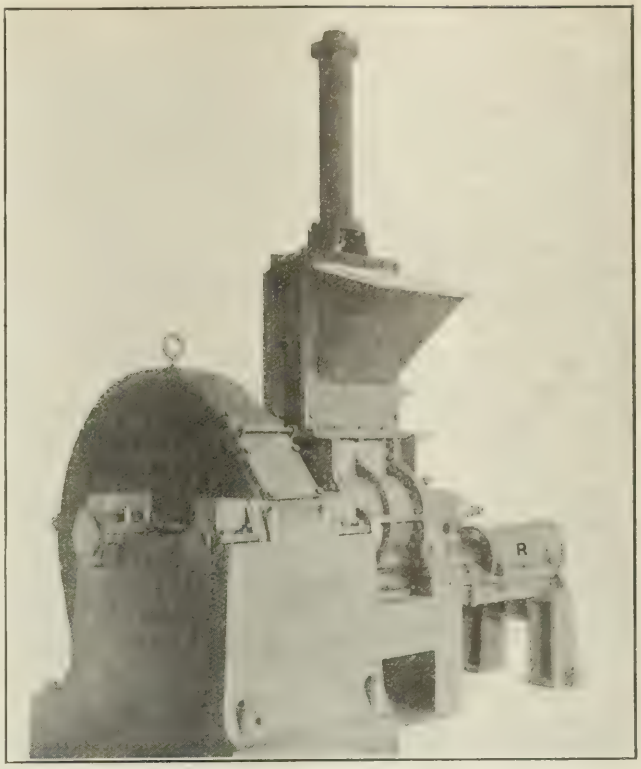

FIG. 2—BIRMINGHAM-BANBURY MIXER

carbon black, but continued production runs made with master batches processed in this manner established beyond question that these batches are tougher and do not work up as soft on a mill as the corresponding mill-mixed material.

Facts which were established by this series of experiments were that the chamber of the machine must be nearly full to mix properly, the rubber must be dry and in a fairly plastic state before the addition of compound, and the compound must be introduced slowly, at a fairly uniform rate, so that the mixing mass maintains its continuity and does not break up into lumps. The distribution of compound was evidently fairly uniform as shown by physical tests on vulcanized stock, but the mixed batch was tougher than corresponding mill-mixed material. I might add that the rotor speed was 23 r.p.m.

Tire Stocks Could Not Be Completely Compounded in Internal Mixer

Attention was now turned to work on tire stocks containing sulphur and accelerator. It was considered desirable to study the effect of variation in speed, and this was done between a range of 18 and 30 r.p.m. of the rotor. It was found that for high-grade stocks increase in speed is accompanied by increase in heat generated, power consumption and slipping between the rotor and the stock.

The range of 21 to 23 r.p.m. was fixed as the most satisfactory for these stocks. For lower-grade stocks where softeners are used and there is less rubber, the speed may be increased to give a shorter mixing time with a much lower proportional increase in heat and power consumption. It was found that for any batch weight or speed which was established it was impossible to mix accelerator and sulphur into the batch in the internal mixer. Most batches permitted the mixture of sulphur at the very end of the mix, although in some

it was found advisable to add only the accelerator. In any case either the sulphur or the accelerator had to be added to the batch on the batching-out mill. The temperature ranged from 90 to 120 deg. C. on the outcoming stock, the speed was held around 20 r.p.m., the average horsepower was about 130, but the maximum horsepower varied from 175 to 275. The time of mixing ranged from 18 to 30 minutes. This included stocks with gravities from 1.0 to 1.62. It is interesting to note that although all these batches could be mixed without scorching by the addition of accelerator or sulphur, after the batch came out of the mixer the resulting compound was found without exception to be tougher than that regularly mixed on mills. This toughness is not of the nature of set-cured stock, but stock in which the rubber has not been sufficiently broken down.

Several different types of mechanical goods stocks, ranging from a cheap bumper stock to a black heel, were tried out and good results were obtained, except that even in these stocks toughness was noticeable, which was not ordinarily found. The time of mixing was much less and the batch weight much greater as compared to tire compounds.

Summary

This study on internal mixers has brought to light three inherent defects:

1. The ratio of cooling surface to volume of stock being less than for a mill batch and the rate of working being greater, heat is generated sufficiently fast to increase the temperatures considerably above those which are ordinarily obtained in mill work. This renders it impossible to mix an entire batch in the mixer without scorching.

2. The resulting mix, although uniform, is tougher than that obtained from a mill. This apparently is due to the fact that the mechanical action is different from that obtained with mill rolls. We have suspected for some time that rubber which is made plastic by heat differs from rubber which is made plastic by mechanical action. It is true that the softening of rubber by mechanical action is always accompanied by a certain amount of heat. Nevertheless, with proper cooling, the effect of mechanical action may be made to predominate. We have observed that rubber softened by heat alone, provided the temperature is not excessive, although apparently much softer when hot, eventually reverts to more nearly its original state than rubber softened by working on the mill. This phenomenon agrees very closely with that observed in connection with the internal mixer. We have already observed that the temperatures obtained are much higher, and it therefore seems logical to assume that the softening action which renders the mixing of the rubber and compound possible in an internal mixer is chiefly due to the heat generated. This is probably chiefly a decrease in the viscosity of the rubber without any great amount of depolymerization and hence we get reversion or toughness after the batch has cooled off.

3. An internal mixer is not a complete unit, but requires the use of a mill to slab off the mixed stock. It is difficult to balance up batching-off mill capacity with mixer capacity, due to the fact that the volumes of different batches vary somewhat and the treatment on the batching-off mill varies depending on the sulphur or accelerator which must be added at that point. Also, it is necessary to batch out stock immediately after it

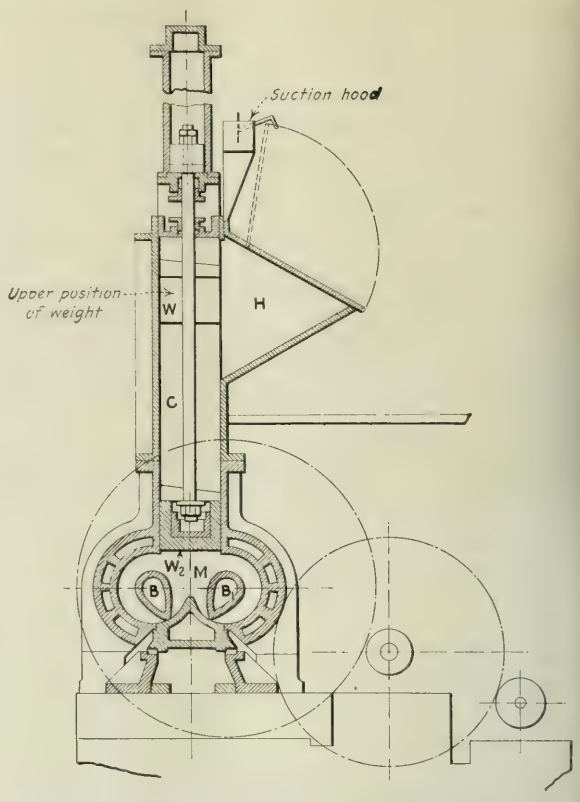

FIG. 3—DIAGRAMMATICAL CROSS-SECTION OF BIRMINGHAM-BANBURY MIXER

is taken from the mixer—particularly if the batch contains sulphur—because of the detrimental effect of the high temperature, which is maintained for a long period if the stock is left in large lumps. This means that the batch-out mills must be synchronized with the mixers. We have made a study of labor and power costs and believe it would be the most economical arrangement to erect a mixer on top of a suitable size mill with an integral drive. This arrangement would permit of dropping the charge directly into the mill rolls, would save trucking and insure rapid cooling of the charge after mixing.

In conclusion I will say that of the three defects mentioned, the first two appear to me to be inherent in the internal type of mixer, but of course the last can be readily remedied by design. I should like to point out that for certain type of stock, particularly mechanical goods, this type of mixer has great advantages over the regular mixing mill. Moreover, where a uniform plastic condition of a mixed stock is not highly essential or where fast curing organic accelerators are very little employed, it will undoubtedly be possible to handle high-grade stocks satisfactorily. In any event the reduction of the dust nuisance and the saving of labor will make it worth while for every manufacturer to study the mixer in connection with his own particular mixing problem.

Fig. 1 shows the standard mixing mill, which consists of two steel rolls driven in opposite directions in such a way as to draw the rubber between the rolls when inserted from above. The surface speeds of these rolls are slightly different, usually in a ratio of about 9 to 10. The rubber is sheeted around the slower roll and is cut back and forth with a knife until the right softness is attained. Then it is left running in such a way that a bank or roll of rubber is formed between the rolls, and fillers, sulphur, accelerators, etc., are added on top of

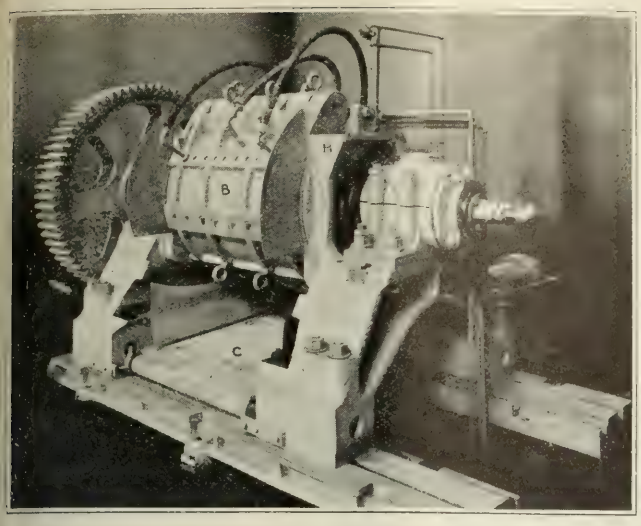

FIG. 4—FARREL MASTICATOR

the rubber, with a shovel. No cutting of the rubber is done during this stage of the mixing until all the filler is worked in.

Fig. 2 is a photograph of the Birmingham-Banbury mixer manufactured by the Birmingham Iron Foundry, Derby, Conn.

Fig. 3 shows a diagrammatical cross-section of the same machine. *H* is the hopper fitted with a cover and suction hood to take care of the dust. *W* is the weight which is raised by means of air piston to permit the introduction of the batch to be mixed through the hopper and cylinder *C* to the mixing chamber *M*. After the batch is introduced, the weight is lowered to the position W_2, thus forming an inclosed mixing box. The blades *B* revolve in such a way as to clean the walls of the chamber and work the batch back and forth. The blades and walls of the chamber are water-cooled. The batch is emptied by the operation of a hydraulic ram which displaces laterally the bottom plates of the mixing chamber, and permits the batch to fall down into a receptacle or onto a conveyor belt. The ram referred to is marked *R* in Fig. 2.

Fig. 4 is a masticator manufactured by the Farrel Foundry & Machine Co., Ansonia, Conn. The ingredients for the batch are introduced through the hopper *H*, which is duplicated by an exactly similar hopper at the other end of the machine. Material may thus be fed in from both ends. Inside the barrel of the machine *B* is a rotor, each half of which is in the form of a worm or screw. The direction of twist is such that the materials are forced toward the center from each end, causing a pile-up of material in the middle, which is relieved by the back-flow between the screw and the inside walls of of the chamber, thus giving an action which mixes and works the ingredients back and forth. The walls and screw of this machine are water-cooled. The batch is emptied by releasing a section of the mixing chamber, which permits the batch to fall on the conveyor belt *C*.

Aluminum Bronze for French Coins

Subsidiary coinage of aluminum bronze is to replace the paper notes now in circulation in France.[1] P. H. Gaston Durville, with M. Hanriot as chemist and principal assistant, have been working on the problem of new coinage alloys since 1909. They have succeeded in producing sound ingots of greenish-gold metal which conform to the several requirements of coinage metal: attractive; corrodes and tarnishes with difficulty and

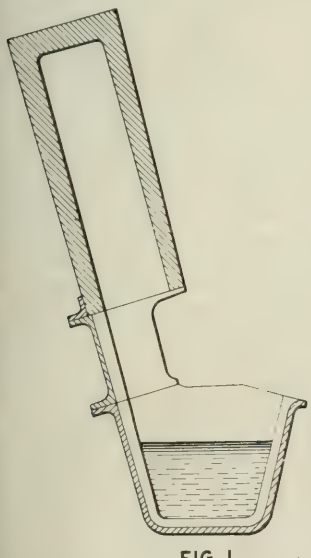

FIG. 1

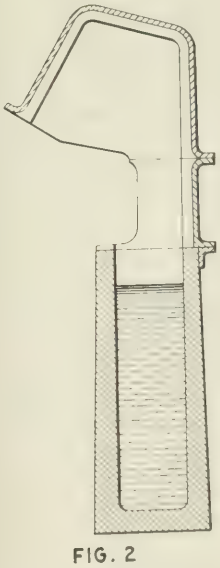

FIG. 2

especially retains its color in sea air; forgeable, yet with sufficient difficulty to discourage counterfeiters; fairly hard.

In manufacture, it was found very difficult to cast sound slabs, free of slag, gas bubbles or dirt. To overcome this, Durville has devised and patented a rotating, composite mold, diagrammed in Figs. 1 and 2. Crucible-melted alloy is skimmed and poured in the refractory-lined receiving basin as shown in Fig. 1. Immediately, and without the least jarring, the mold is rotated slowly into the position shown in Fig. 1. Four slabs, weighing 60 to 70 kg. each, are thus cast simultaneously; the pouring basin is removed and the slabs drawn as soon as they have solidified.

[1] *The Engineer*, July 21, 1922, p. 74.

Chilled-Iron Car Wheels

In view of the fact that the 5,000-lb. wheel loads of the freight car in use 50 years ago were carried on chilled-iron wheels weighing 525 lb., while today a similar wheel weighing 850 lb. is called upon to bear 25,000 lb., an investigation to determine the actual capacity of the wheel has been under way for several years, jointly under the auspices of the Association of Manufacturers of Chilled Car Wheels and the University of Illinois Engineering Experiment Station. Bulletin 129, by J. M. Snodgrass and F. H. Guldner, presents the first installment of their findings, on the strains in M.C.B. wheels due to pressing the wheel on the axle and due to static loads.

Tensile strength of specimens cut from wheel plates varied from 23,300 to 32,800 lb. per sq.in., and the modulus of elasticity from 14 to 28 million. These figures cannot be predicted by hardness tests.

Forcing the wheel on the axle stresses the wheel most highly in tension in a tangential direction at the bore. The outer face is stressed in compression in a radial direction. Brackets take no material load.

Static loads are transmitted from the hub to the rail mainly through the outer plate, and do not add greatly to the strains induced by mounting the wheel on the axle. It seems therefore that very great static loads may be safely carried by the present wheel.

Book Reviews

DICTIONNAIRE ANGLAIS-FRANÇAIS-ALLEMAND DE MOTS ET LOCUTIONS INTÉRESSANT LA PHYSIQUE ET LA CHIMIE. By *R. Cornubert*. xxxii + 297 pages. Paris: Dunod, Éditeur, 47, Quai des Grands-Augustins. Price, broché, 42 fr.; relié, 47 fr.

While a good technical dictionary is almost indispensable for any investigator who has to keep in touch with foreign literature, it is also true that the real usefulness of such a book is directly proportional to the ease with which it yields the desired information. Most three-language dictionaries are divided into three separate sections or even volumes, as English-French-German, French-German-English, German-English-French. By means of an ingenious arrangement, M. Cornubert has been able to combine these three into a single one with three parallel columns containing English, French and German words respectively. In each column the word whose translation is desired is set in black-face type while the equivalents appear on the same line in the other columns in ordinary type. With this procedure, a single alphabetical arrangement suffices for the three languages, as is evident from the following excerpt:

pilot burner	**veilleuse**	Sparflämmchen
vector	vecteur	**Vektor**
velocity	vitesse	Geschwindigkeit
loop	**ventre**	Bauch
to generalize	généraliser	**verallgemeinen**

An introductory section gives general data on German technical nomenclature, lists of English and German abbreviations and irregular verbs and of English units.

With its thorough treatment of technical terms in the fields of chemistry and physics and its rapid reference features, this dictionary should prove an invaluable aid to the busy technical man. ALAN G. WIKOFF.

ANALYSIS OF NON-FERROUS ALLOYS. By *Fred Ibbotson, D.Met., B.Sc., F.R.C., Sc.I., F.I.C.*, and *Leslie Aitchison, D.Met., B.Sc., A.I.C.* Second Edition. 246 pages. Longmans, Green and Co., London and New York, 1922. Price, $4 net.

As stated by the authors in preface to this second edition, they have added some new matter, consisting chiefly of methods for the analysis of light alloys of aluminum and of alloys of nickel. Otherwise the material presented has been reprinted without change from the first edition, issued in 1915. It includes chapters on apparatus for, and general description of, electrolytic analysis, on precipitation and comparative solubilities of the sulphides of the elements occurring in non-ferrous alloys and on methods of determination for these elements separately. The remaining chapters, occupying the smaller part of the volume, treat of methods specially applicable to commercial alloys. The general classes of non-ferrous alloys are covered by special methods for brass, bronze, phosphor tin, german silver, white metals, aluminum and nickel alloys and stellite. The added methods in this edition, besides those given for aluminum and nickel alloys, include methods for the separation of aluminum and zinc and for the determination of small amounts of elements which may be present in special brasses and bronzes. This new material comprises altogether about 22 pages.

The subject of analysis of non-ferrous alloys is probably covered more completely by this book, and by one other of American authorship, than by others published. However, in treating this subject it would be better if there could be given more detailed descriptions of methods of analysis for the various types of non-ferrous alloys and modifications required according to percentage composition. For instance, it would be well not only to give general methods for determination of white metal alloys but also to describe necessary details for applying the method to the separation and determination of tin in cable sheathing, where it is present to the extent of only 3 per cent, as well as in tin base-bearing metals, which may contain as much as 90 per cent and where it is necessary to separate tin from antimony and copper, as well as possibly from lead.

It should not be necessary to include in a treatise on this subject all of the important single methods of determination for each element, as this is the province of text-books on general quantitative analysis, but it would be desirable to include specific methods applicable to the separation and determination of elements present in particular alloys. The authors have described in the main part of the book most of the various methods for determination of separate elements, without in general stating which is preferable and without giving limits of accuracy. As an illustration of this, there is given under Antimony, as one of the gravimetric methods, a description of its determination as tetroxide, a method which is very seldom used. From the text one would not be able to learn where this method could be best applied or whether it might be more or less accurate than the other methods described. Under Volumetric Determination of Antimony four different methods are given without information as to probable accuracy or other means of judging which should be given preference. On the other hand, there is no mention made of certain methods which are very frequently used in analysis of alloys. For instance, under Lead, there is no description of its gravimetric determination as chromate, and under the analysis of White Metal Alloys no mention is made of a method which has been found generally useful and has been included in Standard Methods of the American Society for Testing Materials—namely, Thompson's method for alloys of lead, tin, antimony and copper, published in the *Journal* of the Society of Chemical Industry, 1896.

The style used by the authors in describing methods is a pleasing feature in that accurate descriptions of the operations to be followed are given without including explicit instructions as to capacity and shape of apparatus to be used, etc.—that is, directions are given so as to be perfectly intelligible to a chemist, without including detailed description of manipulation to be carried on by a laboratory assistant.

WILLIAM A. COWAN.

THE DETERMINATION OF SULPHUR IN IRON AND STEEL. By *H. B. Pulsifer*. Cloth, 9¼x6¼. 160 pages. The Chemical Publishing Co., Easton, Pa., 1922, Williams & Norgate, 14 Henrietta St., Covent Garden, W. C., London, England.

The author is to be congratulated upon his originality of publishing a book which covers but one element in iron and steel. He published his method for the determination of sulphur in iron and steel in the 1916 *Journal of Industrial and Engineering Chemistry*, vol. 8, p. 1115, in which a comprehensive list of the bibliography was published.

The present volume deals with the evolution method for determining sulphur in iron and steel, consisting essentially of using a strong solution of hydrochloric acid in a 500-c.c. flask containing a glass stopper which is water-cooled with a glass worm extending about one-third of the distance into the flask. The bibliography is very complete and covers references on the sulphur determination in iron and steel from 1797 to 1921. Illustrations are also given showing micrographs and sulphur prints of sulphide areas. The book is well written and contains descriptions of sulphur methods which have been published, including comparative results obtained by various methods.

The author recommends the use of hydrochloric acid, specific gravity 1.19, for determining sulphur by evolution, and on page 52 a table is given covering the use of six different sulphur methods and the results obtained on five different samples. The nitric acid method has a tendency to yield low results. This is also true of the dilute hydrochloric acid method. The least variation is shown in the concentrated hydrochloric acid evolution method. From the low results obtained when using dilute hydrochloric acid, it would appear that the use of concentrated hydrochloric acid is desirable. The importance of dispensing with rubber connections from which sulphur may be derived is dwelt upon. It is necessary to use a condenser when using concentrated hydrochloric acid, otherwise the acid will distill over and quickly neutralize the alkaline cadmium chloride solution.

On page 46 reference is made to the analytical results obtained with standard methods, and in each instance the

tudents found some sulphur in the ron. (An anomalous statement is nade that the results may be a 100 per ent too high or 100 per cent too low. As there can be no more than 100 per ent, it is difficult to see how the results ould be a 100 per cent too low, if the tudents obtained any sulphur whatever!)

Taken as a whole, the book is well dited, it covers the subject very fully nd is recommended to those interested n the various methods for determining ulphur in iron and steel.

J. A. Aupperle.

The Electrometallurgy of Steel. By *C. C. Gow*. 351 pages. New York: D. Van Nostrand Co. Price $7.50.

This recently published book gives he historical development of the electric furnace and considerable information on the electrical characteristics of he various types of furnace, a portion of the book being given up to highly heoretical electrical features of various furnaces. This possibly represents the author's chief interest. The matter relating to the metallurgical side of the problem is a summary of what has been covered in previous literature. The whole book presents no very striking advance in presenting known facts, but if one wishes an elementary survey of the general field it will be found in this volume, presented in very readable style.

Frank Hodson.

Synopsis of Recent Chemical & Metallurgical Literature

Lead Baths

In a paper read before the Detroit meeting of the American Society for Steel Treating, R. B. Schenck, of the Buick Motor Co., described an extensive use of lead baths for hardening and tempering axle shafts, transmission gears and other parts. It is a heating medium which is easy to control, heats the work uniformly, and without chemical action of any sort. Great uniformity of results is therefore easily possible.

Lead baths can be operated at any temperature from 650 to 1,700 deg. F. Lead will never stick to the work if the surface of the bath is kept free from a floating scum of oxide. This is best accomplished by maintaining a thin protective coating of granular carbon—some material like charcoal, having a low kindling temperature, is best. If annealing or tempering baths tend to leave an adherent metal film on the work, the articles may be plunged, immediately upon withdrawal, into molten caustic soda at a slightly lower temperature, and then into cold water. A molten salt cover works all right on lead for a few days, but thereafter the whole mass tends to get mushy.

Cast iron pots can be used for baths operating below 1,300 deg. F.; cast steel gives better results for hotter work. If direct flames are not permitted to strike the pot, it will last for months—the principal corrosion being at the surface of the melt. Rectangular pots, hung from a lip at the top, are very satisfactory, especially if heated from below by a single flame traveling from one end to the other and then deflected back again by proper baffle walls and partition. Deep round pots should be rested on a brick pier, and heated by tangential, swirling flames.

One hundred and thirty-five pounds of work can be heated to 1,500 deg. F. per gallon of oil burned, or if the waste gases be used for warming a preheating pot, the figure can be doubled. Double handling of the work may cost more, however, than the oil saved. If kept well covered, lead consumption should not run over ½ lb. per 100 lb. steel treated. About 1¼ lb. of charcoal cover is burned per sq.ft. of surface per hour.

Refractories for Zinc Smelting

Requirements for refractories used in the zinc industry are considered by G. C. Stone, of the New Jersey Zinc Co., in the September *Journal* of the American Ceramic Society, p. 597.

In roasting furnaces of the Hegeler type, which are most extensively used, refractory trouble is caused by the furnace design. These furnaces are very large, about 80 ft. long, 17 ft. wide and 30 ft. high. Everything is in two parallel sections. Starting from the bottom each section has regenerative chambers, and above, three gas chambers, seven roasting hearths and frequently special air passages. The arches are both set on the center wall. The life of the furnaces is long, as there is but little corrosion or wear and the temperatures are not excessive, but the load acting on the center wall, which is maintained at a relatively high temperature, causes it to settle badly. This settling is very serious, as it is not uncommon to find the inner side of the hearths 5 in. lower than the outer, which interferes materially with the operation of the furnace. It should be possible to burn brick so that even long-continued heating to a temperature of about 850 deg. C. and never exceeding 900 deg. C. would not cause a shrinkage of from 1 to 3 per cent.

In zinc oxide furnaces the temperature is only about 1,000 deg. C., but the sudden changes caused by air cooling, when the furnaces are cleaned out and charged every 6 or 8 hours, and the rather severe handling in breaking up and removing the charge often damage the brick. Dense hard-burned brick are best.

Spelter furnace linings have to stand a high temperature for long periods with a regular daily variation between 800 and 1,400 deg. C. Practically the whole lining is made of special shapes, which are often made by the smelters themselves.

Retorts are also made by the smelters as they are placed in the furnaces red hot from the kilns in which they are burned. They should be capable of standing a temperature of 1,600 deg. C. without deflecting materially when supported only at the ends, with a clear span of about 4 ft. They must be dense, so as to be impervious to gases and zinc vapor, which tends to form zinc spinel.

Condensers are not subjected to temperatures above 600 deg. C., but they get rather rough handling as they are taken down and scraped each morning. They are also always made by the smelters.

Brick are often blamed for defects when the short life is due to poor brick-laying. From observation the author concludes that less than 5 per cent of the brick used are laid in a manner calculated to give the best results and fully half are badly laid.

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Separating Gaseous Hydrocarbon Mixtures—The process is described with particular reference to the recovery of acetylene from mixtures with other hydrocarbons of relatively lesser solubility, but it is pointed out that other gases such as ethylene, propylene and the like can be similarly separated by a process of differential solubility. Practically complete separation is accomplished by solution at low temperature and high pressure with subsequent progressive increase in temperature and gradual elimination of the dissolved gases. By this means the gases first evolved from solution are returned to the solution chamber and the relatively soluble component which comes out of the solution last is separated from the balance almost pure.

Further development of this idea is presented in a second patent which discusses several variations of the basic idea. A still further development in a third patent relates more particularly to the separation of ethylene from mixtures with other hydrocarbons. (1,422,-182-183-184. George O. Curme, Jr., assignor to Union Carbide Co. July 11, 1922.)

Manufacture of Acetylene Products—The patent contemplates a process of producing products from acetylene by passing it, together with another reacting gas, over hydrated metal compound, oxide, bog-iron ore, or other iron compound with hydrated alumina or with an oxygen-yielding compound at temperatures ranging from 250 to 500 deg. C. The production of catalysts is also covered by the patent. These are the various oxides or hydrated metal compounds, either as first formed or in a partly reduced state, prepared by passing hydrogen or other moist reducing gas over the hydrated oxide at

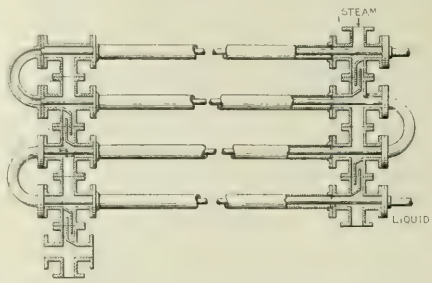
about 400 deg. C. The third group of claims covers the process for making compounds between acetylene and hydrogen sulphide by passing over appropriate catalysts at the temperatures named.

Five examples are given of typical applications of the patent. In the first, acetylene with four times its quantity of steam is passed over bog-iron ore at 400 to 420 deg. C., forming acetaldehyde as the chief product. It is claimed that 15 to 16 per cent of the acetylene is converted in a single pass. The second example relates to acetylene and a small amount of steam over partly reduced bog-iron ore for the production of the higher aldehydes, acetone, alcohol, acetic acid, furfurane derivatives, phenols, etc. The third example relates to acetylene and ammonia passed over bauxite at 350 to 380 deg. for production of nitriles and other nitrogen-containing bases to the extent of 50 per cent of the acetylene used. The fourth and fifth examples given relate to acetylene and hydrogen sulphide combinations used in contact with nickel hydroxide or bauxite for the production of thiophene, mercaptan, etc. (1,421,743. Bernhard Conrad Stuer and Walter Grob, assignors to the Chemical Foundation, Inc. July 4, 1922.)

Carbonaceous Product — This patent covers a product obtained by treating "rotted coal" with alkaline solution and the method of making the product. It is claimed that disintegrated coal treated with alkali produces a solution which would be useful as a fertilizer or as a raw material in the making of certain dyestuffs, etc. It is also suggested that a suspension of this rotted coal be used as a means for collection of ammonia from coal or coke-oven gas, the product being used as a fertilizer instead of ammonium sulphate. (1,420,754. Hugh Rodman, assignor to Rodman Chemical Co. June 27, 1922.)

Evaporator—This invention relates to evaporators; and it comprises an evaporator having tubular heating elements arranged in a vertical series with a substantially continuous evaporating tube passing through the several elements, the elements in each tier having a trapped liquid drain to the element below whereby to bypass condensed steam out of the path of heating vapors going through the series; and it more particularly comprises an evaporator of such a type wherein the trapped liquid drain is formed by co-operating and complementing unions, each said union having a flanged passage provided with a cuplike element having a portion extending beyond the flange plane and the elements being so shaped that on assemblage of two unions they together form a liquid-sealed trap.

In the well-known Kestner type of evaporator, evaporation is performed on what is termed a "climbing film"; liquid goes upward through a steam- or vapor-heated vertical tube, first as a sort of foam and finally as an annular ascending film with a central current of vapor traveling at a rather high velocity. For reasons of space it is sometimes desirable to use the same type of apparatus and operation in horizontal tubes rather than vertical; the evaporator tube being constituted of superimposed horizontal end-connected tube sections. In so doing, the surrounding heating element or jacket is likewise made as a series of superimposed sections connected together. In practice it is desirable that these jacket sections be rather narrow, giving a narrow annular pathway for the heating vapor or steam along the evaporator tube sections. The heating vapor flows through the system countercurrent to the liquid to be evaporated.



The difficulty with this construction is that condensed steam is apt to clog the long narrow pathway of the heating vapor at one point or another. Evaporators of this type have a high evaporative capacity with a concomitant absorption of heat, and the amount of condensate is considerable. It is necessary that the supply of steam or heating vapor be ample and that it flow through the heating elements with as little friction or interruption as may be from bodies of condensate. It is the object of the present invention to provide means whereby condensate in the heating elements may be bypassed downward from tier to tier out of the path of vapor in the narrow horizontal heating elements; the bypass connections being so arranged as to give a liquid seal to prevent flow of vapor. (1,424,254. Ralph Mellor, assignor to Kestner Evaporator Co., of Philadelphia, Pa. Aug. 1, 1922.)

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Titanium—Titanium dioxide is obtained from titaniferous bauxite by heating the finely powdered ore, preferably under a pressure of 3 to 4 atmospheres, with five parts of ammonium sulphate at a temperature of 350 to 400 deg. C. The iron and alumina present are converted into soluble double sulphates, with evolution of ammonia, the silica and titanium dioxide remaining unchanged. The product is treated with water, when the iron and aluminum salts pass into solution and the titanium dioxide forms a fine suspension. Silica and undecomposed ore are permitted to settle, and the suspension of titanium dioxide decanted off and filtered. Specification 15,590/06 is referred to. (Br. Pat. 181,775. E. E. Dutt and P. C. Dutt, London. Aug. 16, 1922.)

Artificial Filaments—A solution of starch or starchy matter in a large quantity of strong sulphuric acid and consisting of products intermediate between starch and glucose is used in the setting bath in the place of glucose in the manufacture of filaments, films, etc., from viscose as described in specification 21,405/07. Preferably, the moisture content of the starch, etc., is reduced to 5 per cent or less, and the dried starch is added rapidly and with continuous stirring to the acid which has been previously cooled to below 0 deg. C., for example to —5 deg. C.; after a homogeneous mixture has been obtained, the liquid is permitted to warm up spontaneously in order to complete the solution of the starch; before use, the mixture is diluted with water, and to the solution may be added sulphuric acid, sodium, ammonium or magnesium sulphate, or a zinc salt. (Br. Pat. 181,900. Courtaulds, Ltd., and M. T. Callimachi, London. Aug. 16, 1922.)

Phosphoric Esters—Mixed esters of phosphoric acid are prepared in known manner from parent materials which are either artificial mixtures of phenols containing at least 25 to 30 per cent of ortho- or meta-cresol, or the acid oils, either as a whole or single fractions therefrom, containing mixed monovalent phenols with at least 25 to 30 per cent of ortho- or meta-substituted homologs of phenol, which are produced in working up various tars, such as coke-oven tar or gas-works tar, low-temperature tar, mineral coal tar or brown coal generator tar. The method employed may be treatment with chlorine or oxygen compounds of phosphorus, such as phosphorus oxychloride or phosphoric anhydride; or the phosphoric di- and mono-chlorides from a single phenol or mixtures of phenols may first be prepared and then converted into the neutral esters. The products are slightly fluorescent viscous oils, useful as softening agents. (Br. Pat. 181,835. Chemische-Fabrik Griesheim-Elektron, Frankfurt-on-Main. Aug. 16, 1922.)

Phenol Condensation Products—The initial oily condensation product obtained by heating phenol with formaldehyde in the presence of sodium sulphite is mixed with a compound containing the CH_2OH or CH.OH group and the mixture heated; the liquid product obtained may be converted into a hard infusible product by heating without pressure, or may be mixed with mineral fillers (clay, talc, mica, etc.), molded and heated to give products suitable for electric insulation or building purposes, or the liquid product dissolved in an organic solvent may be used for coating or impregnating paper or paper board, which is then hot-pressed and heated. Suitable hydroxy compounds are oxy-fatty acids such as glycollic, lactic, malic, tartaric or citric acid; alcohols, such as glycerol, butyl, amyl, ceryl, cetyl or myricyl alcohol, or cholesterol, or glucose, levulose, mannose, maltose, mannite, cane sugar, etc. (Br. Pat. 182,886. S. Satow, Tokyo. Sept. 6, 1922.)

Chemical Foundation Files Formal Answer

Statement of William D. Guthrie, Counsel for the Chemical Foundation

THE CHEMICAL FOUNDATION has filed its answer to the suit of the government in Wilmington, Del. The answer is a comprehensive and emphatic denial of the government's charges. It denies that the Chemical Foundation participated in any conspiracy or monopoly or suppressed any information from the President or his representative, Assistant Secretary of State Frank L. Polk, or paid an inadequate consideration for the patents, or did any act in bad faith or unlawfully. The answer, on the contrary, points out that before any patents were sold to the Chemical Foundation every material fact bearing upon the creation of the Chemical Foundation, its objects, its work and its doings was discussed in the official report made to the President by A. Mitchell Palmer as Alien Property Custodian on Feb. 22, 1919, and transmitted by the President to Congress. An extract from this report is annexed to the answer as an exhibit. From this report it appears that the whole plan concerning the Chemical Foundation and its taking over of the German patents was disclosed in detail.

It is claimed in the answer, in addition, that not only were the President and Polk and Congress and the country generally advised of the plans which gave rise to the Chemical Foundation and the taking over by it of the German patents, but that Palmer as Alien Property Custodian also explained the situation personally to the President and to his representative, Frank L. Polk, and that after such report and such explanation, they made the orders authorizing and approving the sales which the present administration now challenges and seeks to nullify.

Seizure of Patents Defended

The answer points out that the taking over of the German patents was necessary to the proper prosecution of the war against Germany, for the common defense in case of renewal of hostilities or future war, and for the emancipation of the American chemical industry from German control and domination.

It narrates in detail how Germany had succeeded, by means of patents and otherwise, in obtaining complete control over the organic chemical industry of the United States. That meant that before the recent war Germany not only controlled the supply of dyes in the United States, but also that the materials out of which poison gas, high explosives and important medicines, like salvarsan, were entirely in the hands of the Germans. The answer insists that in such a situation the ability of the United States to manufacture high explosives and to defend itself according to the means and methods of modern warfare were at the mercy of Germany; that the ability of the United States to supply its citizens with important medicines was likewise at the mercy of Germany, and that many of its most important businesses were equally at the mercy of Germany. The report to the Alien Property Custodian, which was given to the President and which is annexed to the answer, shows how it was necessary to break this control of Germany over the chemical industry of the United States, if the United States was to have the power adequately to defend itself and protect its citizens.

Not a Private Venture

The President approved the policy of Americanizing the basic industries of the United States in order to overcome the German domination of those industries the answer points out. To that end the Chemical Foundation was formed, after conference with the President and his representative, Frank L. Polk, and with their approval, and after similar conference and approval, the patents in suit were transferred to the Chemical Foundation in order that it might hold and administer them in the interests of America and secure to the United States the permanent freedom of the organic chemical industry from German or other hostile foreign domination.

It further appears from the answer that on the President's return to this country, the orders made by Polk were brought to his attention and that the matter was again considered by him and that he thereupon made an order duly ratifying in all respects what had been done by Polk and the Alien Property Custodian.

The answer shows that the Chemical Foundation is not a private venture; that it has made and can make no profits for private persons; and that, on the contrary, it has expended thousands of dollars of its own capital to accomplish the public and patriotic purposes of President Wilson and its founders. Thus the Chemical Foundation is not like the ordinary owner of a patent, shutting out some persons from the use of it while giving others the right to use it as it sees fit. Under its charter and under its agreement with the Alien Property Custodian, the Chemical Foundation is required to and has and does license all American citizens who are qualified without discrimination and at equal rates and upon like terms.

The Chemical Foundation is also the means which was adopted to enable the United States to avoid having to pay heavy damages for patent infringements to Germans who had taken out patents of the United States, not in order to help American science and industry, but to throttle it. That was accomplished by having the patents sold to the Foundation and a release and license given by the Foundation to the government.

The answer concludes by praying that the complaint be dismissed.

Helium Production for Aircraft Will Soon Be Commercial

For the encouragement of the friends of lighter-than-air craft, Dr. R. B. Moore, chief chemist of the Bureau of Mines, who is in charge of the research work on helium being done jointly by the War and Navy Departments and the Bureau of Mines, declares the present situation is another instance in which it is darkest just before dawn. In Dr. Moore's opinion, the future of lighter-than-air craft never has been brighter. Experimentation in the cryogenic laboratory of the Bureau of Mines leads Dr. Moore to believe that within the next decade 99.9 per cent helium will be produced at a cost as low as $20 per 1,000 cu.ft.

Thanks to the perseverence and unselfishness of the Linde Co. and certain scientists, the problems of helium production have been solved. All that remains to be done is to reduce the costs of production. Since American ingenuity has solved a hundred more difficult problems, Dr. Moore has every reason to believe that the production cost of helium will be reduced rapidly.

Once helium can be produced at a moderate cost, Dr. Moore expects to see the lighter-than-air ship take its place as one of the permanent agents of transportation.

University of Buffalo Inaugurates Capen

Dedication of New Chemical Laboratory Precedes Installation—Smith and Slosson Speakers

Samuel P. Capen of Washington, a member of the Society for Promotion of Engineering Education, has resigned as director of the American Council on Education to become chancelor of the University of Buffalo. He was installed Saturday, Oct. 28. The day preceding the inaugural, Foster Hall, the new $1,000,000 chemical laboratory of the University of Buffalo, was dedicated, the speakers being Edgar F. Smith of Philadelphia, president of the American Chemical Society, and Edwin E. Slosson of Science Service, Washington.

Special interest attaches to Dr. Capen's new position from the technical standpoint, because he is going to Buffalo for the avowed purpose of trying to carry into effect a system of "job analysis" for the professions that may pave the way toward elimination of useless frills in technical and academic education. Dr. Capen has been active in the educational relations of the National Research Council and during the war served on committees that aided the War Department in organizing the higher institutions of the country to make the most effective contribution to the war enterprise.

Dr. Capen was invited to become a member of the Society for Promotion of Engineering Education because of the excellence of the work he did while with the federal Bureau of Education, in evolving the technique by which the vital facts relating to the policies, financial administration and educational effectiveness of the institution being surveyed could be ascertained.

The New Laboratory

The new University of Buffalo laboratory is specially designed to meet the peculiar needs of the steel, dye, electrochemical and hydro-electric industries on the Niagara frontier and in western New York, which more and more are relying upon the university-trained man for important technical and administrative positions. The laboratory is not the largest, but it is believed to be the equal if not superior to any in the world. Many of the ideas of Prof. L. M. Dennis of Cornell, who for years has been studying the question of proper chemical laboratory construction, are embodied in the building.

One large room is so constructed that walls may be added or be torn out, according to the requirements of special work under way. The building includes a metallurgical, industrial, inorganic, organic, analytical, advanced analytical, miscroscopy and research laboratories, with private laboratories on a smaller scale for the professors.

The chemical laboratory is the gift of O. E. Foster, a Buffalo philanthropist, and is the first unit of the Greater University of Buffalo to be erected on the newly acquired 150-acre campus at the north end of the city, where an unusual educational experiment is to be carried on. Indicative of the backing the university has from the citizens of Buffalo is the fact that 2 years ago in an endowment fund campaign they contributed $5,000,000 in large and small amounts.

DR. SAMUEL P. CAPEN

Quebracho Forests in Danger of Extinction

The danger of the extinction of the quebracho forests of Argentina and Paraguay is imminent, according to H. M. Hoar, of the Research Division of the Department of Commerce. The total available tonnage of quebracho standing in 1922 has been liberally estimated at 71,300,000 metric tons for Argentina and 3,500,000 metric tons for Paraguay.

A minimum estimate of the potential production of quebracho extract by the companies now operating in Argentina and Paraguay is about 240,000 metric tons per annum, and as one ton of quebracho extract represents about 4¾ tons of logs, it would require an annual felling of 1,400,000 metric tons of quebracho wood for tannin purposes alone in these two countries.

Add to this the annual cut for construction work, paving blocks, fuel, telegraph and telephone poles, for which quebracho wood is extensively used, also an estimated annual requirement of 3,600,000 railway sleepers, 1,600,000 fence posts and an annual exportation of quebracho logs, varying from 108,945 metric tons in 1917 to 56,582 in 1920, and the duration of the present stands of quebracho wood can be readily grasped, together with the necessity for forest protection and the restoration of denuded tracts.

Describes Methods of Organic Chemist

Prof. W. Lee Lewis, Retiring Chairman Addresses Chicago Section, A.C.S.

To the layman the ways of all chemists are mysterious, but the organic chemist is frequently little understood even by fellow scientists whose work is confined to other branches of the subject. A decided step toward better mutual understanding was made Friday evening, Oct. 20, when Prof. W. Lee Lewis addressed the Chicago section of the American Chemical Society on "The Organic Chemist at Work." Taking as a typical problem the action of acetylene on arsenic trichloride in the presence of aluminum chloride, Dr. Lewis outlined step by step the methods of attack leading to the accumulation of sufficient data to enable large-scale production of a compound which because of its peculiar physiological properties was in demand at the time for military purposes.

Preliminary work on the reaction mixture having shown that the product consisted of a number of related compounds, one of which was more desirable than the others, studies were next conducted to determine the conditions which would give the greatest yield of this compound.

Following the main address were the group meetings which have become such a successful and helpful feature. The formality which is more or less inherent in a large gathering is not found in the smaller groups and this, together with the opportunity for more lively discussion, is very effective in increasing acquaintanceship among the members.

Laboratory Cost Accounting

Before the group on inorganic laboratory methods, A. W. Landstrom outlined a simple method of cost finding for a commercial laboratory. It was originally developed in order to determine whether the charges made for analyses were fair to both the customer and the laboratory, but was found so useful generally that it is kept up regularly. Time reports are made out for each analysis and from these the cost is determined as follows: The product of the number of hours and the analyst's rate per hour gives the direct cost. Fixed charges or overhead, and cost of materials and equipment for a year are divided by the number of man-hours per year to give the indirect cost on a man-hour basis. This is simpler than trying to figure the cost of materials, etc., for each type of analysis. The indirect cost is then the time multiplied by the man-hour factor, and this plus the direct cost gives the total. This system requires very little time and so costs practically nothing.

Topics at the other group meetings were: "Research Problems of the Baking Chemist," C. B. Monson; "1:4 Addition," C. D. Lowry; The Wassermann Reaction With Syphilis and Its Interpretation," J. J. Moore.

Tariff Commission Reorganized to Conform With New Rules of Procedure

Provision for Rate Changes Places New Responsibilities on Commission Which Will Be Met by Modified Organization

THE RULES of procedure under which the United States Tariff Commission will apply its enlarged powers were made public Oct. 26. On the same date William S. Culbertson, vice-chairman of the commission, in the course of an address before the American Manufacturers' Export Association, revealed the details of the reorganization of the commission to meet its new requirements. In that connection he said:

"The law provides that all investigations under Section 315 are to be made by the United States Tariff Commission and that the President shall issue no proclamation changing rates or classification until after the Tariff Commission shall have investigated. The commission has, as a result of these new responsibilities, completely reshaped its organization. Under the commission there are now four broad divisions: (*a*) The office of the chief investigator, (*b*) the office of the chief economist, (*c*) the legal division, (*d*) the secretary.

Detail of Organization

"The secretary handles the routine business of the commission. To the legal division are referred questions of customs laws and procedure and any other legal question that may arise in the commission's work. General investigations which the commission may conduct under its general investigational powers will be supervised by the chief economist, and special investigations made necessary by the new powers vested in the President will be under the direction of the chief investigator.

"The commission's organization under the direction of the chief economist and the chief investigator consists of a series of divisions each with a chief and other experts. These divisions are: chemicals, pottery and glass, metals, wood and paper, sugar, agriculture, textiles, leather, sundries, preferential tariffs and commercial treaties, and accounting. In addition, the commission has provided for the establishment of a New York office.

"The work of the commission's staff is co-ordinated in an advisory board which reports only to the commission and is under its immediate direction. The chief investigator is chairman of this board. Its other members are the chief economist, a representative of the legal division and the chief of the division of the commission concerned in the subject matter under consideration.

New Rules of Procedure

With regard to the new rules of procedure Mr. Culbertson said: "The first step in defining the commission's procedure was the issue on Oct. 7 of an executive order by the President directing that all applications for investigation under the new provisions "be filed with or referred to the United States Tariff Commission for consideration and for such investigation as shall be in accordance with law and the public interest, under rules and regulations to be prescribed by such commission."

"Today the commission gives publicity to its rules of procedure. They set forth how applications for investigations shall be made and under what conditions and in what manner the commission will conduct formal investigations upon which the President may change the tariff law. Anyone can apply for an investigation. The application need not be in any special form, but it must be in writing and signed by or on behalf of the applicant. It must also recite the relief sought and the reasons therefor. Obviously, the mere filing of an application does not obligate us to proceed formally. We shall not order an investigation unless the application or a preliminary investigation discloses to our satisfaction that there are good and sufficient reasons for doing so under the law.

"We can order a formal investigation upon our own initiative as well as upon application and we are not confined to the issues presented in an application; we may broaden, narrow or modify the issues to be determined.

Plan for Hearings

"When we finally decide to proceed formally with an investigation, we shall issue and publish a notice of its nature and scope. Any person who then can show to our satisfaction an interest in the subject matter of the investigation may enter his appearance in person or by a representative. He will be notified of public hearings and afforded opportunity to offer such testimony as we may deem necessary for a full presentation of the facts. Our hearings will usually be open to the public. Evidence submitted will be subject to verification from the books and records of the parties in interest. In conjunction with hearings we shall conduct field investigations both in the United States and in foreign countries.

"In the case of formal investigations our procedure will be judicial in character. Our rules provide for the attendance and examination of witnesses, the production of documentary evidence, the issuance of subpœnas and the taking of depositions. The commissioner or investigator in charge of any investigation will summarize the hearings and the information obtained by field investigation and will prepare a report. Parties of record will be permitted, before they file their briefs, to examine this report, as well as the record, except such portions as relate to trade secrets and processes.

"Final hearings will, of course, be before the commission. Parties of record may file briefs and in some cases present oral arguments. Our findings will be in writing, and will be transmitted with the record to the President for his action."

Muscle Shoals Report to Be Given Publicity

Senate Committee on Agriculture to Circulate Majority Findings

The printed record of the Muscle Shoals hearing conducted by the Senate Committee on Agriculture and Forestry during the last session of Congress is to be widely distributed. It is pointed out that it is important that those who mold public opinion which controls legislative action should know the facts concerning matters of this character. Accompanying the record will be the following letter signed by George W. Norris, of Nebraska, the chairman of the committee:

> So much misinformation has been published and propaganda spread over the country by real estate boosters and others personally interested, that many good citizens, farmers, farmers' organizations and commercial and civic bodies have urged Congress to accept without qualification the offer of Henry Ford to take over for 100 years the war-built nitrate plants and appurtenances at Muscle Shoals, in Alabama, which cost $90,000,000, and the uncompleted water-power dam on the Tennessee River in which the government has invested $17,000,000, in all about $107,000,000.
>
> Contrary to a general idea, Mr. Ford does not agree to reduce the price of fertilizer one-half, one-third or even at all, although he stipulates he must have 8 per cent profit on the cost, whatever that may be; he does not agree to reimburse the government the additional $50,000,000 to $60,000,000 required to carry out his proposed contract, nor does he in fact agree to pay 4 per cent interest thereon for a lease for 100 years of the power dams and electrical equipment. For $5,000,000 he acquires public property worth many times that amount, and exclusive use and control for 100 years of immense water power developed at government expense for about 2¾ per cent annual interest on the cost thereof, free of regulation, restriction or control by any public authority. He is exempt from the terms and provisions of the national water-power law passed 2 years ago to protect and conserve the interest of the public in the water-power resources of the nation, without obligation that any portion will be used by municipalities or industries in the South, but admittedly for the sole use of Mr. Ford in his own plants and his successors. He does not pledge his personal fortune or estate to the faithful performance of any obligation assumed by the corporation he will organize. He does not agree to repay the government all future outlays for repairs and maintenance, and whatever alleged public benefit proposed is not in any sense commensurate with the special and unusual privileges sought for one individual or corporation.
>
> Whether the Muscle Shoals project is controlled or operated by the government or by private or quasi-private concerns, the public interest in a great navigable river and the water power that follows the improvement of navigation, as well as the products of plants constructed with public funds, should be conserved, used and distributed for the common welfare.

It is pointed out that the public should be informed of the facts in this matter, for its own protection, and should understand that the majority report was submitted after weeks of thorough investigation and taking of a mass of expert testimony.

Formula Is Devised for American Valuation

Customs Division Calculation Sounds Like Recipe for Home Brew

The customs division of the Treasury Department has devised and issued to collectors a formula for determining United States value as defined in the tariff act of 1922 and which is to be the basis of assessing duties on non-competitive coal-tar products in contra-distinction to American valuation which is to be applied to duties on competitive coal-tar products.

Subdivision D of Section 402 of the new tariff act reads: "The United States value of imported merchandise shall be the price at which such or similar imported merchandise is freely offered for sale, packed ready for delivery, in the principal market of the United States to all purchasers, at the time of exportation of the imported merchandise, in the usual wholesale quantities and in the ordinary course of trade, with allowance made for duty, cost of transportation and insurance, and other necessary expenses from the place of shipment to the place of delivery, a commission not exceeding 6 per cent, if any has been paid or contracted to be paid on goods secured otherwise than by purchase, or profits not to exceed 8 per cent and a reasonable allowance for general expense, not to exceed 8 per cent on purchased goods."

Valuation of Coal-Tar Products

In interpreting this, the customs division has instructed collectors to ascertain the dutiable value by taking the selling price in the United States, dividing by 108, subtracting the quotient from the selling price, then dividing this remainder by 108 in the case of purchased goods or by 106 in the case of goods where that commission has been charged, subtracting this second quotient and from this remainder subtracting the transportation and insurance charges and the specific duty. The final remainder, divided by 100 plus the ad valorem duty, which in the case of finished coal-tar products is 60 per cent, gives the dutiable value, according to this formula.

Some importers have insisted that the proper way would be to divide immediately by 116, rather than have two operations. This would lower the duty somewhat.

Feldspar Producers Recognize Need of Trade Association

Inability on the part of a considerable number of the feldspar producers and grinders to be present at a meeting held at the Bureau of Mines Oct. 25 made it impossible to carry through at that meeting the plan to organize a national association within the industry. It was felt by those present that the action should not be taken until the industry could be more generally represented.

Another effort to obtain the attendance of a representative number of those interested in the industry will be made at the coming meeting of the United States Potters' Association. At that meeting it is hoped to perfect plans for the organization.

The discussion among those who attended the meeting in Washington indicated a determination to have a national organization. It was pointed out that the feldspar industry is unique in that no other industry with as much capital invested is denying itself the benefits of the constructive functions which trade associations perform.

New Laboratory at Yale to Be Dedicated

Ceremony Will Be Feature of Spring A.C.S. Meeting at New Haven

The dedication of the new Sterling Chemical Laboratory of Yale University on April 4, 1923, will be a feature of the spring meeting of the American Chemical Society at New Haven. This arrangement has just been completed by national officers of the society and officials of the Yale Corporation. The dedication ceremony, with probably 1,500 or 2,000 members of the American Chemical Society in attendance, as well as the Yale faculty and student body, probably will be one of the most impressive affairs of its kind ever held.

The new building is one of the finest in the world and is built on an entirely new architectural principle. The main building is constructed on three sides of a square, three stories high and is in harmony with other buildings on the campus. In this building are class and lecture rooms, private laboratories and offices. Inclosed in the square is a one-story, saw-tooth roof type of factory building, with movable partitions. This structure can be changed to suit the various needs of the teaching staff. It is constructed to give the maximum of light and air and equipped so that it can be converted into several small workshops or one large shop, equal in size to a small commercial chemical plant.

Committee Chairmen

The following are chairman of the several committees for the meeting: Program, T. B. Johnson; finance, J. S. Gravely; dedication, John Johnston; registration, Blair Saxton; arrangement, A. J. Hill; hotels and transportation, Ralph Langley; smoker, P. T. Walden; reception and entertainment, C. H. Matthewson; publicity, W. T. Read; ladies' entertainment, Mrs. John Johnston.

The Chi chapter of Alpha Chi Sigma is to have charge of the information service of the meeting. Headquarters are Room 157 Sterling Chemical Laboratory, New Haven, Conn.

The scientific meeting will be under the auspices of the New Haven and Connecticut Valley sections of the society. Prof. Treat B. Johnson of Yale is chairman of the executive committee in charge, chosen from members of the two sections.

Seventy Million Yearly for Research

Chamber of Commerce Report Points Out Value and Place of Trade Associations

American industry is spending about $70,000,000 annually on scientific research, according to the Fabricated Production Department of the Chamber of Commerce of the United States. About one-half of this sum is spent by American manufacturers in the conduct of laboratory research, while the remainder is expended in experimental and development work in plants. As a result of scientific research work approximately one-half billion dollars is being saved annually by industry in this country.

"The value of scientific research, both from an economic and industrial standpoint," the department says, "has never been so fully appreciated as at the present time. The problems of the recent war forced science and its research activities to the front in all civilized countries. It is now realized by leading manufacturers that scientific investigation is a necessary adjunct to efficient co-operation. A utilization of the scientific knowledge now available and a sympathetic co-operation in the free interchange of such information will lead to the adoption of improved manufacturing processes and do much to obviate the danger of ignorant, destructive competition. The realization of this fact is shown by the 500 or more firms now maintaining laboratories for industrial research.

Trade Associations Correlate Work

"If there were no correlation of effort on research work, much duplication might result. The logical solution, therefore, is to have the trade association make this correlation. This enables a pooling of resources to maintain a central laboratory to render service to a larger group than is possible with only individual laboratories. Another and very important factor, especially valuable in strengthening trade associations, is that such centralized research work makes it possible for the small manufacturer, financially unable to support an individual laboratory, to profit from the investigations.

"It is not surprising, therefore, that a continually increasing number of trade associations are realizing the value of research as one of their most constructive activities. Of the sixty-five to seventy associations now engaged in this work to whom a recent inquiry was sent by the Fabricated Production Department, thirty-three gave specific replies, indicating that eight were conducting their research independently, and twenty-five were acting in co-operation with some other agency. The general leaning is toward the scientific aspect of research work. Nineteen trade associations are engaged exclusively in that class, three in the general problem class, while eleven give attention to both types of problems."

To Compile Import Statistics on Dyes

Government Will Keep Manufacturers Informed on Prices

So that domestic chemical manufacturers may be advised promptly as to the exact character of imports, the Chemical Commodity Division of the Department of Commerce will compile each month detailed information as to the imports of synthetic organic chemicals. The report will be mimeographed and a limited distribution of it made in that form.

Now that the selective embargo has been removed, manufacturers have indicated great interest in the prevailing current prices on important and typical products of foreign chemical industries. The Department of Commerce is arranging with its representatives in chemical centers for a cable service which will quote the actual prices at which these chemical products are being sold (not the prices at which they are offered). It is the intention to publish price information in mimeographed form for distribution to the trade.

The articles on which the prices are most desired are: Dyes—acid black, auramine, bismarck brown, direct black, fast light yellow, indanthrene blue, indanthrene violet, indigo, methyl violet, patent blue, rhodamine B conc., sulphur black, sulphur blue, wool green; intermediates — aniline oil, benzaldehyde, benzidine, betanaphthol, H acid, acetanilid, aspirin, choral hydrate, gallic acid, metol.

Personal

O. Otis Bowman, 2nd, has resigned his connection with the Trenton Fire Clay & Porcelain Co., with which he has been associated for a number of years, to devote his entire time to the Bowman Coal Co., Trenton, N. J., of which he is secretary and treasurer.

Dr. T. R. Duggan will be the guest of honor at a dinner to be held at the Chemists' Club, New York, Friday, Nov. 3. Dr. Duggan, a former trustee of the club and chairman of the house committee, leaves for England shortly.

Alfred D. Flinn has been elected director of the Engineering Foundation which is fostering organized industrial research on a nationwide scale. Mr. Flinn is the first incumbent of the new post, created by the Foundation's governing board, composed of the four founder societies of civil, mining, mechanical and electrical engineers, to meet the expanding activities of the Foundation. Mr. Flinn will retire as chairman of the Engineering Division of the National Research Council, a position which he has held since October, 1921, but will continue as secretary of the United Engineering Society in order that the Foundation may continue intimate relations with the founder societies. Mr. Flinn has been secretary of this society and the Foundation since January, 1918, and is widely known by engineers throughout the country.

Louis J. Gurevich, formerly with the Hydraulic Steel Co., Cleveland, Ohio, is now metallurgist for the Owens Bottle Co., Toledo, Ohio.

Dr. H. J. Hamburger, professor of physiology, University of Groningen, Holland, addressed the Washington Academy of Sciences, Biological Society of Washington and the Chemical Society of Washington (D. C.) on Oct. 19. His address was on "The Increasing Significance of Chemistry in Medical Thought and Practice."

F. E. Hamer, editor of *Chemical Age*, London, who came here as a representative of Benn Bros, Ltd., to the meetings of the Associated Business Papers, Inc., and the National Conference of Business Paper Editors, sailed for home on the Baltic, Oct. 28.

Dr. Ellwood Hendrick spoke at the opening meeting of the Baltimore Section of the American Chemical Society at the Engineers' Club, Friday, Oct. 27, on "The Vision of Science."

E. E. Hunt, of Springfield, Ohio, has been selected as the secretary of the President's Coal Commission. Mr. Hunt has been in charge of the study of intermittency in the coal industry, which the Department of Commerce has been pursuing since last March. For the purposes of that study a contribution was made from the Cabot fund. The study was an outcome of the unemployment conference, of which Mr. Hunt was secretary. Mr. Hunt had been associated with Mr. Hoover throughout the preparation of the report on waste in industry.

Dorsey A. Lyon, chief metallurgist of the Bureau of Mines, is at the Minneapolis experiment station supervising test runs on the new blast furnace.

Prof. Emmanuel de Margerie of the University of Strassburg, French exchange professor in applied science and engineering, has arrived in America to take up work at seven leading engineering schools. The lectures begin at Columbia University.

Dr. C. E. K. Mees, director of the research laboratory, Eastman Kodak Co., Rochester, will give an illustrated lecture entitled "Chemistry and the Motion Picture" before the Society of Engineers at Troy, N. Y., Nov. 14, the Detroit Section of the American Chemical Society on Nov. 15, the Purdue Section of the American Chemical Society at Lafayette, Ind., Nov. 16, and the Chicago Section of the American Chemical Society on Nov. 17.

Frederick Stugard, formerly chief chemist and superintendent of the Kosmos Portland Cement Co., of Louisville, Ky., has accepted a position with the National Cement Co. of Birmingham, Ala., as chief chemist at its plant at Ragland, Ala. He was connected with the Kosmos Portland Cement Co. from the day it started production in 1905, and served in various capacities as assistant chemist, chief chemist, assistant superintendent and superintendent during the course of his employment at the plant at Kosmosdale, Ky.

Obituary

Dr. Ralph R. Potter, chemist recently engaged in the research department of The Barrett Co., Edgewater, N. J., from which he resigned on account of ill health, was drowned in Lake Nashotah, near Oconomowoc, Wis., on Oct. 13. He was undergoing treatment at a local sanitarium, to recover from a complete physical breakdown.

Colonel Jared Rice Smith of Augusta, Ga., died on Oct. 10. Colonel Smith was born in Berryville, Clark County, Virginia, July 27, 1847. According to the *American Fertilizer*, at the age of 16 he joined the Confederate Army and served throughout the remainder of the war. At its conclusion he returned to Clark County, Virginia, and shortly after became clerk of court of Clark County, which office he held for a number of years. He was subsequently engaged in mining in Virginia; and later, while still a young man, became associated with the George W. Graflin Co., of Baltimore, in the fertilizer-manufacturing business. He went to Atlanta for it and in 1880 removed to Augusta to take charge of its Southern business, making his home in that city. He became president of the Georgia Chemical Works, which office he held up to the time of his death. A part of the intervening time he lived at Richmond, where he was general sales manager of the Virginia-Carolina Chemical Co. In 1913 he returned to Augusta, and had since resided there.

In 1903 Mr. Smith was married to Mrs. Anna Platt Heard, of Augusta, who survives him as well as one son, Charles L. Smith, of New Mexico, and two daughters by an earlier marriage, Mrs. Hamlin P. Briggs, of Raleigh, N. C., and Mrs. Edwin Calhoun, of Chester, S. C.

Mr. Smith was a great sufferer for the last 3 years of his life, having developed angina pectoris 3 years ago. At that time it appeared as though he could live only a short time, as his suffering was intense during the attacks. However, he was afforded a measure of relief by his physician, and a method of treatment was adopted which if instantly available could check the attacks. He made a magnificent fight for 3 years.

In the early hours of Oct. 10, Mr. Smith was seized with a sudden attack, and died in a few minutes. He was buried in Summerville cemetery, the Hill, Augusta, Ga., on the afternoon of Oct. 12. The civic bodies of Augusta, and the Rotary Club, of which he was a life member, attended the funeral in a body from the Church of the Good Shepherd, of which Mr. Smith was a member.

Mr. Smith was indeed the dean of the fertilizer industry, to which he had given practically his whole active life. He was an honorary member of the National Fertilizer Association.

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities
Prevailing Prices and Market Letters From Principal Industrial Centers

Economics—Is It a Basis for Sound Executive Action or Is It Bunk?

The Established Value of Economic Principles to Business Trends Brings Up the Question, Are They Useful to the Individual Business?

IT IS NOT inappropriate at this moment to consider the subject of economics and its relation to business. The report of the convention of the Society of Industrial Engineers which appears on another page of this issue summarizes the opinions of prominent men on this timely subject. But such conventions must and do speak generalities. What we are really interested in is the *argumentum ad hominem*. How does economics affect my business? True, the index number is going up, but my costs and selling prices are not affected. True, someone told me that Babson predicts better business for a while at least, but mine has not changed or is worse than in April. Is this economics stuff sound or is it bunk? How can it benefit me in my decisions?

A Characteristic Reaction Against Economics

Let us get down to a few brass tacks if possible and endeavor to locate the connection between the general and the particular. First let us look at Babson. I was talking to a textile manufacturer during the winter of 1920. He was wealthy and successful. He was not war wealthy, but wealthy because of 40 years of successful effort. "Economics is all right in its place," he remarked, "but you can't run a business from Babson's charts. The movements are too general to make specific application possible."

Just about that time Babson began to shout "Beware!" "Look out for the inevitable deflation period!" Executives with orders booked 6 months ahead for full capacity laughed, if they paused even long enough to do that. A few stopped and thought and then they stopped buying raw materials and cut down inventories. "Idiots!" exclaimed the rest of the world if they knew. And then—well, the story is history now. The deflation came with a dull thud and business failures reached unprecedented heights. Babson and those who studied economics were right. They expected and were prepared for deflation. Economics "worked" in business problems. All logic aside and all pet theories eliminated, America's most rigid test has been applied—the pragmatic test. Does it work? Is it successful? If it is, it's right. And economics has established beyond a doubt its utility in business, your business, my business, any business.

Babson's Use of Statistics and Their Economic Interpretation

To return to Babson for a minute and the so-called Babson chart. Those of you who subscribe to his service know what the chart is: It is a weighted index, a composite of twelve subjects. Each subject has intrinsic value as a sign of business health or the lack of it. At present these twelve subjects which are composited include check transactions, new building, failures, money rates (domestic and foreign), foreign trade, commodity prices, stock prices, railroad earnings, crops, Canadian conditions, immigration. Each of these is carefully weighted, seasonal variations are allowed for and a composite curve is constructed which might be called the curve of business value. This curve is studied in relation to another curve called the country's net gain or growth. During boom periods the business curve is above the net growth curve and during periods of depression it is below it. The area between the two curves during a boom period will equal the area below during the subsequent period of depression on the assumption that action and reaction will inevitably be equal. We are at present over half way through the reaction period which followed the war boom, with conditions on the mend.

Arbitrary and Therefore Unreliable, Howls the Critic

It will probably at once occur to many that the weighting on such a chart is of necessity arbitrary, that the curve representing the country's net growth is also arbitrary and that when you subtract one arbitrary unit from another the result can have but little significance. The answer to that is that it works. You can argue yourself blue in the face. You can invoke the old saying (and many do): There are lies, damn lies and statistics. You can say complacently that you'd rather have a man with business sense than all the economic statistics in the world (and many say that too). But you can't blast away the fact that this chart, with whatever empirical limitations there are, has been a reliable indicator of business health.

We are not trying to sell Babson. In fact we are not sure that we are not already liable to a copyright law-suit for the discussion so far. But the point that we wish to make is that economic statistics which are studied in the light of economic laws reveal business conditions accurately and no one can afford to neglect them.

The Individual Enterprise and Not Business in General

A Complementary Study by the Executive Necessary

Neither Babson nor anyone else would attempt or pretend to run a business solely on a basis of such a chart of general business conditions. Small variations which would break even large corporations must inevitably be lost in the vast composite sweeps of the curve. What you as the head of a business unit should do in addition is to construct and study such curves for your own business. Here, for example, is one set of curves which would be of inestimable value (and very few people construct such a set or any curves for that matter). The production curve and the sales and stock reserve curve on each commodity manufactured! Variations in the differences between these two curves could form a reliable basis for production.

An example will illustrate. A company was producing a commodity which had a distinctly seasonal demand. Each year a stock was built up to an arbitrary figure and the plant shut down. Each year inevitably the demand ran away with the stock and

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	157.71
Last week	156.10
November, 1921	146.82
November, 1920	240
April, 1918 (high)	286
April, 1921 (low)	140

Relatively little change in the weighted index over last week's figure. Three commodities dropped slightly, citric acid, nitric acid and linseed oil. The price of acetic acid advanced slightly but not sufficiently to counterbalance the drop of the three others. For practical purposes this change is negligible and taken in connection with information from the various correspondents the market may be considered steady and strong.

orders piled up in spite of night and day production. Each year the stock was increased and each year it was regularly wiped out. The stock became more and more valuable as its size was increased. Each year the argument was more and more heated: increase the plant capacity or the size of the stock before the plant is shut down. The executive was torn between desire to get all the business possible and the hesitancy to tie up capital either in plant or stock. A typical executive problem with nothing but empirical data and the much touted "business sense" to solve it with. The result, confusion!

It is the old story of the psychological dilemma: "I want to eat it, for it looks like a mushroom. But I am afraid to eat it, for it might be a toadstool." For heaven's sake, find out the difference between mushrooms and toadstools and stop worrying. That is just what a study of statistics in the light of economic laws will do to many executive problems. It will show them the difference between mushrooms and toadstools.

We can think of a dozen statistical charts which every business executive will ultimately be using just as assiduously and eagerly as he is using engineering skill now. Why not give the matter thought? If charts work for general business conditions, so they will for individual business conditions. And the man with only "business sense" will ultimately take a place analogous to that which the "practical" engineer holds now—valuable still for his hunches and ideas, but having to be carefully checked by scientific business methods and sound economics.

The Trend of the Chemical Market

The tariff bill went into effect before Oct. 1, but October prices showed the first effect of the new law. Materials which are imported but on which the protection is greater than previously tended to advance. Even some which lost protection showed some advance. Consumers have in general shown much more marked interest and so-called conservative buying methods have to a large extent disappeared. Pronounced optimism is fairly widespread and many large producers are sold up on important commodities.

Exports do not stir observers and dealers to much enthusiasm. Even caustic soda and soda ash buyers have not been inclined to purchase for foreign countries. A hope that this is a passing phase is expressed and activity in the Far East, coming as it does concurrently with Secretary Hoover's ruling, strengthens this hope.

Among the products which rose in price early in the month—all imported products—were barium chloride, barium carbonate, prussiate of soda and caustic potash.

The rise in the price of methanol was the most important single feature. From 72c. per gal. at the beginning to 92c. as the closing price for the month is rather spectacular. Naturally other wood products and derivatives showed a similar but not proportional rise. Formaldehyde went from 10½c. per lb. to 13½c., an exceptional gain, as the price has scarcely varied in the last 6 months. Acetone, all grades of acetic acid and ethyl acetate were affected by the same rise. A new schedule was also given out by manufacturers of lead acetate.

White Arsenic Still Going Up

Commercial white arsenic is still scarce. Opening at 8½c. per lb., it is now selling at 10½c. The demand has been persistent and it is likely to stay so, for although the season is over, producers will undoubtedly attempt to build up exceedingly large stocks during the winter in order to be ready to supply a demand which is likely to be unprecedented next year for the arsenic insecticides.

Phenol, with a rise from 21c. per lb. to 31c. per lb., has also demanded much attention. Spot material is scarce and the rather limited stocks in the hands of dealers are being held for the higher prices which appear inevitable. Producers are in general sold up for some time to come. It is believed that the advance in price is largely due to speculative interests.

Very few reductions were recorded. Oxalic acid and chlorate of soda were forced down to meet foreign competition. Toward the end of the month yellow prussiate of soda, sal ammoniac, barium chloride and permanganate of potash dropped. These declines were largely due to lack of interest and a desire on the part of some dealers to close out stocks.

The market is on the whole strong and large producers are well satisfied with the volume. The next month should show continued strength and volume.

Erratum

We believe that very few of our readers were misled by the obvious error on last week's market pages. In discussing the so-called invisible exchange from America to Europe an estimated value for 1921 of one and one-half million dollars was mentioned. This of course should have been one and one-half billion dollars. We tried to blame the composing room and the proofreader but they produced the manuscript in our own handwriting—it read "million."

Certainly one and one-half million dollars would not be much of a factor in allowing our trade balance to remain favorable and still permit the payment of interest and principal on foreign loans. We apologize and wish to call attention again to Secretary Hoover's ingenious analysis of the situation—an analysis which may have suffered in the eyes of some through our error.

September a Good Month

Steel and Coal Production Indicates Continued Business Activity

The Department of Commerce reports that business activity was maintained during September. Iron and steel production has recovered from its low point in August. Unfilled orders pile up and prices for both iron and steel have increased sharply.

Pig Iron and Steel

The September pig-iron production totaled 2,034,000 tons, or 218,000 tons more than in August, but still below the recent peak of 2,405,000 tons reached in July. Steel-ingot production, prorated to 100 per cent, rose from 2,532,000 tons in August to 2,714,000 tons in September, but is below the maximum reached in May of 3,099,000 tons. Ingot production, so far this year, is nearly 70 per cent ahead of the same months of 1921. Merchant pig-iron production increased in September, but shipments, unfilled orders and stocks all declined.

Unfilled orders of the U. S. Steel Corporation continued to increase in September, reaching a total of 6,692,000 tons, or 742,000 tons more than at the end of August. Structural steel sales declined slightly in September. The movement of iron ore through the Sault Ste. Marie canal showed a decline of nearly 2,300,000 tons, compared with August. The prices of all iron and steel products rose sharply during September.

The production of zinc showed a further increase in September, while stocks continued to decline. Stocks of tin also showed a marked decline, compared with August. The prices of zinc and lead rose during September while tin declined slightly and copper showed no significant change.

Coal Production High

The resumption of bituminous mining at the beginning of September caused the output for the month to rise to 40,964,000 tons, compared to 22,328,000 tons in August. The September production is the largest since October a year ago except for March, when stocks were being built up in anticipation of the strike. Bituminous production has been maintained at a steady level of just under 10,000,000 tons a week ever since the settlement of the strike. The present rate of production is limited only by the ability of the railroads to handle the product.

Anthracite production increased from 161,000 tons in August to 4,979,000 tons in September. Mining in the anthracite field was not resumed until the second week in September; consequently the output for the month is considerably below the 7 to 8 million tons normally produced. Recent reports show that anthracite production is now averaging about 2,000,000 tons per week.

Coke production, both beehive and by-product, increased in September. The price of coke declined somewhat. The same was true of the weighted mine average price of bituminous coal.

A Life-Preserver to Chinese-American Commerce

Secretary Hoover Issues Regulations for Carrying Out China Trade Act

It is safe to say that a large majority of Americans have been unacquainted with the handicap from which American traders in China have suffered. Great Britain, France and Japan long ago had freed corporations engaged in Chinese trade from the burden of their taxation, but American firms the stock of which was owned by Chinese or American residents of China were subject to American income tax regulation. Even some months ago, when a test case was put into the courts and a temporary injunction issued, little progress was made because firms hesitated to make themselves liable for accrued income taxes which might have been levied following an adverse court decision.

The China trade act became a law on Sept. 19 and it effectively removes the handicaps which have hitherto been felt. It provides that stock of corporations engaged in commerce in China, which is held by either Chinese or American residents of China, shall be exempt from federal income taxation. This will have the effect of attracting both Chinese and American capital into trade with America, which will be mutually advantageous.

Such trading is rather more difficult than ordinary exporting, for it means always a two-way trade. American goods can be distributed with a fair degree of ease, but the Chinese goods must be collected in small quantities over a wide area. Large production centers are a modern Occidental development.

A registration and a nominal fee of $100 are all that are required to incorporate a China trade company.

Such information as is necessary may be obtained from the Department of Commerce.

The act is looked on as a great step forward and it is distinctly to be hoped that some of the hundreds of companies which were forced out by the unfavorable conditions will be lured back into the work again.

The New York Market

NEW YORK, Oct. 30, 1922.

A few price changes were about the only features of the chemical market last week. New prices were announced on all grades of acetic acid on account of the upward revision on acetate of lime quotations. Heavy purchases of white arsenic have again caused dealers to advance prices. The prussiates tended to ease off during the past 2 weeks. Producers of chlorate of soda announced a reduction in selling prices. All barium products are being well sustained at recent quotations. Bichromate of soda is holding its firm tendency under a fair inquiry for moderate quantities. The domestic demand for caustic soda and soda ash continues exceedingly heavy and leading producers are quite satisfied with the volume of new business. The export inquiry was rather dormant during the interval. One of the strongest items on the list was phenol. Prices soared to 30c. per lb. early in the week for limited lots, with a very strong tendency toward much higher levels. Producers are sold ahead far into the future and there seems to be no relief for some time to come.

GENERAL AND SPECIAL CHEMICALS

Acetate of Soda—The spot market continues quite firm and sellers are offering limited lots at 8c. per lb. The scarcity of supplies is proving a sustaining feature to the market.

Acetic Acid—All producers announced a new advance on the various grades. Commercial, 28 per cent, packed in barrels, is quoted at $2.92½ per 100 lb. in carload lots. The 56 per cent is being held around $5.85 per 100 lb. in carload lots, and glacial 99 per cent at $11.16 per 100 pounds.

Arsenic Oxide—Spot quotations are slightly higher and it is doubtful if better than 10¾c. per lb. can be obtained. The range is from 10¾@11c. per lb. Recent heavy buying from the insecticides has reduced spot supplies.

Barium Carbonate—Imported material is offered on the basis of $75 per ton on spot. Several fair-sized sales were transacted at this level, with the range up to $80 per ton for smaller lots. Demand was moderate and in most cases for small quantities.

Bichromate of Soda—This market is in a firm position, with leading producers asking 7⅝@7¾c. per lb. Second hands report several sales at 7½@7⅝c. per lb. for spot goods.

Chlorate of Soda—Domestic producers have reduced selling prices to 6¼@6½c. per lb., f.o.b. works, for November shipment. Imported goods on spot is being held at 6¾c. per pound.

Fluoride of Soda—Sales of imported material are reported on the basis of 9¾c. per lb., with the market quite firm at this level. Recent buying has greatly reduced spot supplies.

Nitrite of Soda—Several lots of imported goods were offered at 9c. per lb. on spot and at 8¾c. to arrive. Domestic factors are unchanged in their views at 10c. per lb., f.o.b. works.

Sulphide of Soda—Domestic producers are quoting the market for 60-62 per cent fused at 4¾@5c. per lb. The broken variety is held at 5@5½c. per lb. Importers are offering fused material at 4c. per lb., carload lot basis on spot. Demand is only routine.

Zinc Chloride — Domestic factors quote the fused at 7c. per lb. in quantity lots. Ground material is quoted at 8c. per lb. Importers are offering goods at greatly reduced figures.

Phenol—This item was undoubtedly the strongest commodity on the list. Spot goods was extremely scarce and leading factors reported a well sold up condition. Several odd lots changed hands during the interval at prices ranging from 28c. per lb. early in the week to 31c. per lb. during the latter part. The general tone is quite firm.

VEGETABLE OILS

Linseed Oil—The spot and nearby shipment market is not very active, but futures were in fair demand during the interval. Spot oil held around 88@89c. per gal. in carload lots, with November shipments quoted at 86c.

Castor Oil—Although dealers in this product reported a very firm tone, producers announced a reduction of ½c. per lb. on all grades. The decline was primarily due to keen competition. The No. 3 grade was quoted at 12c. per lb., with the AA at 12½c. per lb. in barrels.

Olive Oil—There has been a pronounced scarcity in prime foots oil and prices on spot are up to 9¾c. per lb. Nearby shipments are being quoted at 9½c. per lb. Denatured oil closed unchanged at $1.15@$1.20 per gal. Edible oil was available at $1.70@$2.30 per gallon.

Peanut Oil—Prices for this material are merely nominal, due to the lateness of the new crop. Prices range from 8¾@9¼c. per lb., tank cars, f.o.b. mills. Refined oil on spot was in limited supply, with quotations heard around 12½@13c. per pound.

The Iron and Steel Market

PITTSBURGH, Oct. 27, 1922.

Steel ingot production is at 36,000,000 or 37,000,000 tons a year, or say 70 per cent of capacity. There has been no important change in the rate since the middle of September, merely a slight further increase after the sharp recovery from the August decrease. All present prospects are that the next change in the rate of production will be a decrease, through some mills not having sufficient orders to maintain their present production rate.

Shipping conditions have improved somewhat. All the current output of steel is being shipped, together with a little of the steel that accumulated recently on account of car shortages. Some embargoes remain, but on the whole there is not much inconvenience in this respect.

The current turnover in the finished steel markets is the lightest for any time this year. The market has been quiet for several weeks and may now be described as stagnant in the majority of lines.

BETTER DELIVERIES OF STEEL

There is no plain evidence that the rate of steel consumption, on the whole, has decreased. There is an easier situation because mills are making better deliveries. Many buyers are still seeking heavier deliveries. They now act upon this desire by urging mills to make heavier deliveries on old contracts, taken at prices below those now ruling, whereas a few weeks ago many buyers were going into the open market and making fresh purchases for early deliveries, paying the delivery premiums then ruling.

There were delivery premiums on bars, shapes, plates and sheets. These premiums have been decreasing for several weeks and they are now relatively unimportant, usually applying only on small lots or on extremely early shipment. In sheets there is the remarkable report that some independent mills are willing to sell, on attractive business, at the Steel Corporation prices, based on 3.55c. for common black, and this is not due to competition by the corporation, since the corporation has been sold out for more than a month, having no further offerings to make until it opens order books for the first quarter of the new year.

Basis Prices Unchanged

Basis prices for steel products, prices that do not contain a delivery premium, are unchanged. In all the products the latest change was an advance, but the only recent advance was that of Oct. 19, in pipe. Bars, shapes and plates are 2c., nails $2.70, tin plate $4.75 and merchant steel pipe 66 per cent basing discount.

The condition in the steel market is a familiar one, new buying having practically ceased, except in cases of new wants arising, in construction jobs, freight cars, etc., while the mills are engaged in filling old orders, taken at various prices during the rise. With the sales policy followed by all the large mills before the war order books would now be of about the same size throughout the industry, relative to capacity. Before the war mills normally sold at the same prices and there was never much difference between prices of the Steel Corporation and the independents. All the authorities in the trade would then have agreed that much difference was obviously impossible. Since the armistice, prices, as between the Steel Corporation and the independents, have been different more often than not. In the past 7 months, since the market passed its low point, there have been various prices, the result being that order books now are of various sizes. The trade, therefore, will not run for as long a time in a quiet period with prices unchanged. Some producers will be disposed to seek additional business by cutting prices while other producers are still well supplied with orders. The price cutting may not lower the general market level or force the mills provided with large order books to modify contract prices at once.

Large consumers of steel are exhibiting a desire to know what steel is going to cost them for 1923 delivery, but are indisposed to attempt to ascertain by starting negotiations. As mills have business on books to protect, they would not name as low prices now as they might be glad to quote a few months hence.

Coke and Pig Iron

Connellsville coke, which had a sharp slump from $12 to $8, as noted in last week's report, has since then merely become a trifle easier. Small lots pressing on the market go at $7.50, while fair-sized lots, for delivery over a week or two, are likely to command $8 and contracts to the end of the year would not be taken at less than $8.50 or $9. Operators are suggesting, as to contract prices, that December is likely to bring fresh car shortages and higher spot prices, whereby contract prices should be higher than the present spot market, to strike the average. It is not shown, however, that the spot market will not decline much more in the next few weeks.

Pig iron continues stagnant, there being scarcely any inquiry. While it is well recognized that the trend in prices is downward and that the market will scarcely halt until it finds a level much below the present, the absence of important inquiry prevents there being much pressure on prices. Bessemer has continued to sell in odd lots at $33 valley. A fair tonnage of basic has sold at last week's quotation of $30 valley. Transactions in small lots of foundry have developed a price of $30 valley, $2 below the quotation of a week ago.

Nickel salt, single	lb.	..... –	.12 – .12½
Phogene (see carbonyl chloride)		..... –	..... – .....
Phosphorus, red	lb.	..... –	.40 – .45
Phosphorus, yellow	lb.	..... –	.30 – .35½
Potassium bichromate	lb.	.10 – .10½	.10½ – .11
Potassium bromide, granular	lb.	..... –	.17 – .23
Potassium carbonate, U. S. P.	lb.	.12 – .12½	.13 – .16
Potassium carbonate, 80-85%	lb.	.06 – .06½	.06½ – .06¾
Potassium chlorate, powdered and crystals	lb.	.07¼ – .08	.08½ – .09
Potassium cyanide	lb	..... –	.55 – .57
Potassium hydroxide (caustic potash)	100 lb.	6.25 – 6.50	6.60 – 7.00
Potassium iodide	lb.	..... –	3.45 – 3.55
Potassium nitrate	lb.	.06½ – .06¾	.07 – .08
Potassium permanganate	lb.	.16 – .16½	.16¾ – .17
Potassium prussiate, red	lb.	..... –	.95 – 1.00
Potassium prussiate, yellow	lb.	.37¼ – .38	.38¼ – .38½
Rochelle salts (see sodium potas. tartrate)		..... –	..... – .....
Salammoniac, white, granular	lb.	.06½ – .06¾	.07 – .07¼
Salammoniac, gray, granular	lb.	.08¼ – .08½	.08¾ – .09
Salsoda	100 lb.	1.20 – 1.40	1.45 – 1.60
Salt cake (bulk)	ton	25.00 –27.00	..... – .....
Soda ash, light, 58 per cent flat, bags, contract	100 lb.	1.60 – 1.67	2.00 – 2.25
Soda ash, light, 58 per cent flat, bags, resale	100 lb.	1.75 – 1.80	1.85 – 2.35
Soda ash, dense, in bags, resale	100 lb.	1.85 – 1.90	1.95 – 2.40
Sodium acetate	lb.	.08 – .08¼	.08½ – .09
Sodium bicarbonate	100 lb.	1.75 – 1.85	1.90 – 2.30
Sodium bichromate	lb.	.07½ – .07¾	.08 – .08½
Sodium bisulphate (nitre cake)	ton	4.50 – 4.60	4.65 – 5.50
Sodium bisulphite powdered, U.S.P.	lb.	.04¼ – .04½	.04¾ – .05½
Sodium chlorate	lb.	.06½ – .06¾	.07 – .07½
Sodium chloride	long ton	12 00 –13 00	..... – .....
Sodium cyanide	lb.	.19½ – .21	.21½ – .25
Sodium fluoride	lb.	.09¾ – .10	.10¼ – .10½
Sodium hydroxide (caustic soda) solid, 76 per cent flat, drums, contract	100 lb.	3.35 – 3.40	3.75 – 4.00
Sodium hydroxide (caustic soda) solid, 76% flat, drums, resale	100 lb.	3.45 – 3.50	3.55 – 4.00
Sodium hydroxide (caustic soda), ground and flake, contracts	100 lb.	3.80 – 3.90	4.25 – 4.40
Sodium hydroxide (caustic soda) ground and flake, resale	100 lb.	4.00 – 4.15	4.40 – 4.60
Sodium hyposulphite	lb.	.02½ – .02¾	.03 – .03½
Sodium nitrite	lb.	.09 – .09¼	.09½ – .10
Sodium peroxide, powdered	lb.	.28 – .30	.31 – .35
Sodium phosphate, dibasic	lb.	.03½ – .04	.04¼ – .04½
Sodium potassium tartrate (Rochelle salts)	lb.	..... –	.18 – .21
Sodium prussiate, yellow	lb.	.22¾ – .23	.23½ – .23½
Sodium silicate, (40 deg. in drums)	100 lb.	.80 – 1.00	1.05 – 1.25
Sodium silicate, (60 deg. in drums)	100 lb.	2.25 – 2.40	2.45 – 2.75
Sodium sulphate, crystals (glaubers salt)	100 lbs.	.85 – .95	1.00 – 1.40
Sodium sulphide, fused, 60-62 per cent (conc.)	lb.	.04 – .04½	.04½ – .05
Sodium sulphite, crystals	lb.	.03½ – .03⅝	.03¾ – .04¼
Strontium nitrate, powdered	lb.	.09½ – .10	.10¼ – .12
Sulphur chloride, yellow	lb.	.04½ – .05	.05¼ – .06
Sulphur, crude	ton	18.00 –20.00	..... – .....
Sulphur dioxide, liquid, cylinders extra	lb.	.08 – .08½	.09 – .10
Sulphur (sublimed), flour	100 lb.	..... –	2.25 – 3.10
Sulphur, roll (brimstone)	100 lb.	2.00 – 2.15	2.20 – 2.70
Talc—imported	ton	30 00 –40 00	..... – .....
Talc—domestic powdered	ton	18 00 –25 00	..... – .....
Tin bichloride	lb.	.10 – .10½	.10½ – .10¾
Tin oxide	lb.	..... –	.39 – .40
Zinc carbonate	lb.	.14 – .14½	.14¾ – .15½
Zinc chloride, gran.	lb.	.07 – .07½	.07¾ – .08
Zinc cyanide	lb.	.42 – .44	.45 – .47
Zinc oxide, XX	lb.	.07½ – .08	.08¼ – .08½
Zinc sulphate	100 lb.	2.75 – 3.00	3.05 – 3.30

Coal-Tar Products

NOTE—These prices are for original packages in large quantities f.o.b. N.Y.:

Alpha-naphthol, crude	lb.	$0.95 — $1.00
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.29 — .31
Aniline oil, drums extra	lb.	.16 — .17
Aniline salts	lb.	.22 — .24
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U. S. P.	lb.	1.25 — 1.35
Benzene, pure, water-white, in drums (100 gal.)	gal.	.30 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.28 — .32
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.80 — .85
Benzoic acid, U.S.P.	lb.	.72 — .75
Benzoate of soda, U.S.P.	lb.	.57 — .65
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.53 — .55
Beta-naphthol, tech	lb.	.23 — .25
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Carbazol	lb.	.75 — .90
Cresol, U. S. P., in drums (100 lb.)	lb.	.14 — .20
Ortho-cresol, in drums (100 lb.)	lb.	.18 — .22
Cresylic acid, 97–99%, straw color, in drums	gal.	.60 — .65
Cresylic acid, 95-97%, dark, in drums	gal.	.55 — .58
Diethylbenzene	lb.	.06 — .09
Diethylaniline	lb.	.50 — .60
Dimethylaniline	lb.	.32 — .34
Dinitrobenzene	lb.	.20 — .22
Dinitrochlorbenzene	lb.	.21 — .22
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.32 — .34
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.85 — .90
Diphenylamine	lb.	.54 — .56
H-acid	lb.	.72 — .75
Meta-phenylenediamine	lb.	.90 — 1.00
Monochlorbenzene	lb.	.08 — .10
Monoethylaniline	lb.	.95 — 1.10
Naphthalene crushed, in bbls.	lb.	.06 — .06½
Naphthalene, flake	lb.	.06½ — .07
Naphthalene, balls	lb.	.07½ — .08
Naphthionate of soda	lb	.58 — .65
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb	10 — .12
Nitronaphthalene	lb.	.30 — .35
Nitro-toluene	lb.	$0.15 — $0.10
N-W acid	lb.	1.20 — 1.30
Ortho-amidophenol	lb.	2.10 — 2.15
Ortho-dichlor-benzene	lb.	.17 — .20
Ortho-nitro-phenol	lb.	.80 — .85
Ortho-nitro-toluene	lb.	.12 — .15
Ortho-toluidine	lb.	.12 — .14
Para-amidophenol, base	lb.	1.20 — 1.25
Para-amidophenol, HCl	lb.	1.25 — 1.30
Para-dichlorbenzene	lb.	.17 — .20
Paranitroaniline	lb.	.72 — .80
Para-nitrotoluene	lb.	.55 — .65
Para-phenylenediamine	lb.	1.55 — 1.60
Para-toluidine	lb.	.85 — .90
Phthalic anhydride	lb.	.35 — .38
Phenol, U. S. P., drums	lb.	.30 — .32
Pyridine	gal.	1.60 — 1.75
Resorcinol, technical	lb.	1.50 — 1.55
Resorcinol, pure	lb.	2.00 — 2.10
R-salt	lb.	.55 — .60
Salicylic acid, tech., in bbls.	lb.	.29 — .30
Salicylic acid, U. S. P.	lb.	.32 — .34
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.27 — .32
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.12 — .14
Sulphanilic acid, crude	lb.	.24 — .26
Tolidine	lb.	1.20 — 1.30
Toluidine, mixed	lb.	.30 — .35
Toluene, in tank cars	gal.	.25 — .28
Toluene, in drums	gal.	.30 — .35
Xylidines, drums, 100 gal.	lb.	.40 — .45
Xylene, pure, in drums	gal.	.40 — .45
Xylene, pure, in tank cars	gal.	.45 — .....
Xylene, commercial, in drums, 100 gal.	gal.	.33 — .35
Xylene, commercial, in tank cars	gal.	.30 — .....

Waxes

Prices based on original packages in large quantities f.o.b. N.Y.

Bayberry Wax	lb.	$0.19½ —	$0.20
Beeswax, refined, dark	lb.	.30 —	.32
Beeswax, refined, light	lb.	.34 —	.35
Beeswax, pure white	lb.	.36 —	.40
Candellila, wax	lb.	.34 —	.36
Carnauba, No. 1	lb.	.40 —	.42
Carnauba No. 2, North Country	lb.	.25 —	.26½
Carnauba, No. 3, North Country	lb.	.19 —	.19½
Japan	lb.	.15 —	.15
Montan, crude	lb.	.03¾ —	.04¼
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.04 —	.04½
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.02½ —	.02¾
Paraffine waxes, refined, 118-120 m.p.	lb.	.03¼ —	.03½
Paraffine waxes, refined, 125 m.p.	lb.	.03¼ —	.03¼
Paraffine waxes, refined, 128-130 m.p.	lb.	.04 —	.04½
Paraffine waxes, refined, 133-135 m.p.	lb.	.04½ —	.04½
Paraffine waxes, refined, 135-137 m.p.	lb.	.05 —	.05½
Stearic acid, single pressed	lb.	.09 —	.09½
Stearic acid, double pressed	lb.	.09½ —	.09¾
Stearic acid, triple pressed	lb.	.10½ —	.10

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl	280 lb.	$7.00 —	.....
Rosin E-I	280 lb.	7.05 —	.....
Rosin K-N	280 lb.	7.10 —	$7.15
Rosin W. G.-W. W	280 lb.	7.75 —	8.25
Wood rosin, bbl	280 lb.	6.25 —	.....
Spirits of turpentine	gal.	1.65 —	1.70
Wood turpentine, steam dist	gal.	1.35 —	.....
Wood turpentine, dest. dist	gal.	1.25 —	.....
Pine tar pitch, bbl	200 lb.	..... —	6.00
Tar, kiln burned, bbl. (500 lb.)	bbl.	..... —	12.50
Retort tar, bbl	500 lb.	..... —	11.00
Rosin oil, first run	gal.	.38 —	.....
Rosin oil, second run	gal.	.41 —	.....
Rosin oil, third run	gal.	.48 —	.....
Pine oil, steam dist., sp.gr., 0.930-0.940	gal.		.90
Pine oil, pure, dest. dist	gal.		.85
Pine tar oil, ref., sp.gr. 1.025-1.035	gal.		.46
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla	gal.		.35
Pine tar oil, double ref., sp.gr. 0.965-0.990	gal.		.75
Pine tar, ref., thin, sp.gr., 1.080-1.960	gal.		.25
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990	gal.		.25
Pinewood creosote, ref	gal.		.52

Fertilizers

Ammonium sulphate, f.a.s., N. Y., double bags	100 lb.	3.65 —	3.75
Blood, dried, f.o.b., N. Y	unit	4.60 —	.....
Bone, 3 and 50, ground, raw	ton	42.00 —	44.00
Fish scrap, dom., dried, f.o.b. works	unit	3.10 —	3.20
Nitrate of soda	100 lb.	2.35 —	2.45
Tankage, high grade, f.o.b. Chicago	unit	4.50 —	4.60
Phosphate rock, f.o.b. mines, Florida pebble, 68-72%	ton	3.50 —	4.00
Tennessee, 78-80%	ton	7.00 —	8.00
Potassium muriate, 80%	ton	33.00 —	34.00
Potassium sulphate	unit	1.00 —	.....

Crude Rubber

Para—Upriver fine	lb.	$0.24 —	.24½
Upriver course	lb.	.18½ —	.18½
Upriver caucho ball	lb.	.18 —	.18½
Plantation—First latex crepe	lb.	22½ —	.22
Ribbed smoked sheets	lb.	22½ —	.22
Brown crepe, thin, clean	lb.	.20 —	.20
Amber crepe No. 1	lb.	.20 —	.20

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls	lb.	$0.12 —	$0.12½
Castor oil, AA, in bbls	lb.	.12½ —	.13
China wood oil, in bbls	lb.	.12¾ —	.12⅞
Cocoanut oil, Ceylon grade, in bbls	lb.	.08¼ —	.08½
Cocoanut oil, Cochin grade, in bbls	lb.	.08¼ —	.09
Corn oil, crude, in bbls	lb.	.08¼ —	.09
Cottonseed oil, crude (f. o. b. mill)	lb.	.07½ —	
Cottonseed oil, summer yellow	lb.	.10¾ —	.10¾
Cottonseed oil, winter yellow	lb.	.11½ —	.11¼
Linseed oil, raw, car lots (domestic)	gal.	.90 —	.91
Linseed oil, raw, tank cars (domestic)	gal.	.87 —	.88
Linseed oil, boiled, in 5-bbl lots (domestic)	gal.	.92 —	.94
Olive oil, denatured	gal.	1.15 —	1.17
Palm, Lagos	lb.	.07 —	.07¼
Palm, Niger	lb.	.06½ —	.06¾
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.08¾ —	.09
Peanut oil, refined, in bbls	lb.	.12½ —	.13
Rapeseed oil, refined in bbls	gal.	.77 —	.78
Rapeseed oil, blown, in bbls	gal.	.85 —	.86
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.11½ —	....
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.08¾ —	.09

FISH

Light pressed menhaden	gal.	$0.51 —	....
White bleached menhaden	gal.	.54 —	.55
Blown menhaden	gal.	.61 —	....
Whale Oil, No. 1. crude, tanks, coast	gal.	.45 —	.48

Miscellaneous Materials

Asbestos, crude No. 1, f.o.b., Quebec, Canada	short ton	$600.00	$800.00
Asbestos, shingle stock, f.o.b., Quebec, Canada	short ton	65.00 —	80.00
Asbestos, cement stock, f.o.b., Quebec, Canada	short ton	15.00 —	17.00
Barytes, ground, white, f.o.b. mills	net ton	17.00 —	23.00
Barytes, ground, off color f.o.b. mills	net ton	13.00 —	21.00
Barytes, floated, f.o.b. St. Louis	net ton	23.00 —	24.00
Barytes, crude f.o.b. mines	net ton	8.00 —	9.00
Casein	lb.	.10½ —	.13
China clay (kaolin) crude, f.o.b. mines, Georgia	net ton	6.00 —	8.00
China clay (kaolin) washed, f.o.b. Georgia	net ton	8.00 —	9.00
China clay (kaolin) powdered, f.o.b. Georgia	net ton	12.00 —	20.00
China clay (kaolin) crude f.o.b. Virginia points	net ton	8.00 —	12.00
China clay (kaoli n)ground, f.o.b. Virginia points	net ton	13.00 —	20.00
China clay (kaolin), imported, lump	net ton	16.00 —	20.00
China clay (kaolin), imported, powdered	net ton	30.00 —	35.00
Feldspar, No. 1 pottery grade	long ton	7.00 —	7.50
Feldspar, No. 2 pottery grade	long ton	5.75 —	5.90
Feldspar, No. 1 soap grade	long ton	7.00 —	7.50
Feldspar, No. 1 Canadian, for mill	long ton	21.00 —	22.00
Graphite, Ceylon lump, first quality, f.o.b. N. Y.	lb.	.05 —	.05½
Graphite, Ceylon chip	lb.	.04 —	.04½
Graphite, high grade amorphous crude	ton	35.00 —	50.00
Kieselguhr, f.o.b. mines, Cal	per ton	40.00 —	....
Kieselguhr, f.o.b. N. Y	per ton	50.00 —	55.00
Magnesite, crude, f.o.b. California mines	per ton	12.00 —	15.00
Pumice stone, imported	lb.	.03 —	.05½
Pumice stone, domestic, lump	lb.	.05 —	.05
Pumice stone, domestic, ground	lb.	.06 —	.07
Shellac, orange fine	lb.	.66 —	.68
Shellac, orange superfine	lb.	.68 —	.70
Shellac, A. C. garnet	lb.	.70 —	.72
Shellac, T. N.	lb.	.65 —	.66
Silica, glass sand, f.o.b. Indiana	per ton	1.50 —	2.50
Silica, sand blast material, f.o.b. Indiana	per ton	2.50 —	5.00
Silica, amorphous, 250 mesh, f.o.b. Illinois	per ton	16.00 —	16.00
Silica, building sand, f.o.b. Pa	per ton	2.00 —	2.75
Soapstone	ton	12.00 —	15.00
Talc, 200 mesh, f.o.b. Vermont	ton	7.00 —	12.00
Talc, 200 mesh, f.o.b. Georgia	ton	7.50 —	12.00
Talc, 200 mesh, f.o.b. Los Angeles	ton	15.00 —	17.00

Refractories

Bauxite brick, 56% Al_2O_3, f.o.b. Pittsburgh	per 1,000	$130.00
Chrome brick, f.o.b. Eastern shipping points	net ton	50
Chrome cement, 40-50% Cr_2O_3	net ton	23–27
Chrome cement, 40-45% Cr_2O_3, sacks, in car lots, f.o.b. Eastern shipping points	net ton	23.00
Fireclay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works	1,000	35–40
Fireclay brick, 2nd quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works	1,000	26–28
Magnesite brick, 9-in. straight (f.o b. works)	net ton	60
Magnesite brick, 9-in. arches, wedges and keys	net ton	70
Magnesite brick, soaps and splits	net ton	90
Silica brick, 9-in. sizes, f.o.b. Chicago district	1,000	48–50
Silica brick, 9-in. sizes, f.o.b. Birmingham district	1,000	50–53
Silica brick, 9-in. sizes, f.o.b. Mt. Union, Pa	1,000	45–47
Silicon carbide refractory brick, 9-in.	1,000	1100.00

Ferro-Alloys

Ferrotitanium, 15-18%, f.o.b. Niagara Falls, N. Y	net ton	$200.00 —	$225.00
Ferrochromium, per lb. of Cr contained, 6-8% carbon, carlots	lb.	.10 —	10½
Ferrochromium, per lb. of Cr contained, 4-6% carbon, carlots	lb.	.10½ —	.11
Ferromanganese, 78-82% Mn, Atlantic seaboard	gross ton	67.50 —	69.00
Spiegeleisen, 19-21% Mn	gross ton	37.00 —	38.00
Ferromolybdenum, 50-60% Mo, per lb. of Mo	lb.	2.00 —	2.25
Ferrosilicon, 10-15%	gross ton	38.00 —	40.00
Ferrosilicon, 50%	gross ton	63.00 —	65.00
Ferrosilicon 75%	gross ton	115.00 —	120.00
Ferrotungsten, 70-80%, per lb. of contained W	lb.	.75 —	.80
Ferro-uranium, 35-50% of U, per lb. of U content	lb.	6.00 —	....
Ferrovanadium, 30-40% per lb. of contained V.	lb.	3.50 —	4.00

Ores and Semi-finished Products

All f.o.b. New York Unless Otherwise Stated

Bauxite, domestic, crushed and dried, f.o.b. shipping points	net ton	$6.00 —	$9.00
Chrome ore, Calif. concentrates, 50% min. Cr_2O_3	ton	22.00 —	23.00
Chrome ore, 50% Cr_2O_3, f.o.b. Atlantic seaboard	ton	19.00 —	20.00
Coke, foundry, f.o.b. ovens	net ton	10.50 —	11.00
Coke, furnace, f.o.b. ovens	net ton	8.00 —	8.50
Fluorspar, gravel, f.o.b. mines, New Mexico	net ton	15.00 —	....
Fluorspar, standard, domestic washed gravel Kentucky and Illinois mines	net ton	17.50 —	19.00
Ilmenite, 52% TiO_2, per lb. ore	lb.	.01½ —	.01½
Manganese ore, 50% Mn, c.i.f. Atlantic seaport	unit	.45 —	
Manganese ore, chemical (MnO_2)	net ton	70.00 —	75.00
Molybdenite, 85% MoS_2, per lb. of MoS_2, N. Y.	lb.	.80 —	.85
Monazite, per unit of ThO_2, c.i.f., Atlantic seaport	unit	27.00 —	....
Pyrites, Spanish, fines, c.i.f., Atlantic seaport	unit	.10½ —	.11
Pyrites, Spanish, furnace size, c.i.f. Atlantic seaport	unit	.12 —	.13½
Pyrites, domestic, fines, f.o.b. mines, Ga	unit	Nominal	
Rutile, 95% TiO_2 per lb. ore	lb.	.12 —	....
Tungsten, scheelite, 60% WO_3 and over, per unit of WO_3 (nominal)	unit	8.00 —	8.25

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

MONTGOMERY — The Woco Pep Co., recently organized with H. H. Gardner, Montgomery, as president, has plans under way for the construction of an oil storage and distributing plant on local site, with initial capacity of about 65,000 gal.

MOBILE—The Mobile Paint Mfg. Co. is planning for extensions in its plant for considerable increase in capacity. Additional machinery will be installed. W. A. Benson is president.

DECATUR—The Alabama Water Co., Albany, Ala., is planning for the installation of a new filtration plant at Decatur.

California

LOS ANGELES—The Pan-American Petroleum & Transport Co., 120 Broadway, New York, with branch at Los Angeles, has tentative plans under consideration for the construction of a new oil-refining plant at Los Angeles Harbor. Application has been made to the Harbor Commission for permission. The company is affiliated with the Mexican Petroleum Co.

LOS ANGELES—Fire, Oct. 9, destroyed a portion of the oil refinery of the Richfield Oil Co., Santa Fe and 24th Aves., including distributing plant, with loss estimated at about $250,000, including buildings and equipment. It is planned to rebuild.

LOS ANGELES—The Atlas Brass Foundry Co. has awarded a contract to V. P. Gilbert, 413 Citizens National Bank Bldg., for the erection of a new 1-story foundry, 36x73 ft., at 1901-3 Santa Fe Ave.

OAKLAND—The West End Chemical Co., producer of borax products, has work under way on extensions to its refining plant at Chauncey, N. Y. Construction of new refineries has also been commenced at Chicago, Ill., and Monongahela, Pa. F. M. (Borax) Smith, San Francisco, heads the organization.

LOS ANGELES — The Ventura Associated Oil Co. has preliminary plans in progress for the construction of a new storage and distributing plant at Los Angeles Harbor.

Florida

TAMPA—The Tampa Gas Co. is planning for extensions and improvements in its artificial gas plant, to include the installation of additional equipment. Roscoe Nettles is general manager.

PALATKA—R. W. Lyle, Palatka, has plans under way for the establishment of a brick-manufacturing plant on local site. The initial equipment will give employment to about 80 men.

BRADENTOWN—The Texas Oil Co. has plans in progress for the construction of a new oil storage and distributing plant on local site. A pumping plant will be installed.

Illinois

CHICAGO—Thayer & Co., manufacturers of soap products, have leased the 3-story building at Armitage and Mango Aves., comprising about 30,000 sq.ft. of floor space, for a new plant. Immediate possession will be taken.

ROCKFORD—The Rockford Malleable Iron Works, Inc., has construction under way on a 1-story plant addition, 90x120 ft., on People's Ave., fronting on the Chicago, Burlington & Quincy Railroad, to be equipped for annealing work. It will cost about $45,000. George C. Forbes is secretary and treasurer.

Indiana

VINCENNES — The Blackford Window Glass Co., recently reorganized with a capital of $1,000,000, has plans in progress for the erection of a new local plant for plate glass production. A tract of 6 acres of land has been secured as a site. The works will include a specialty division for the grinding, polishing and beveling of the output, as well as a clay plant for raw material service. Frank Bastin is president, and Ira D. Schaffer, treasurer.

LAFAYETTE—Fire, Oct. 14, destroyed the oil-distributing and storage plant of the National Refining Co., with loss estimated at about $100,000. It is planned to rebuild. Headquarters of the company are at 1404 East 9th St., Cleveland, Ohio.

Kansas

COFFEYVILLE—The Sinclair Consolidated Oil Co., 45 Nassau St., is making a number of changes and improvements at its local oil refinery, heretofore devoted largely to lubricating oil production, and plans to have the plant complete and in full operation by the close of the year. It will have a capacity of about 5,000 bbl. per day. The company is increasing production at its Kansas City refining plant, which has been handling about 5,000 bbl. daily, and a variety of refined oils are being produced. It is reported that the company is planning for the construction of a second unit at its refinery at Houston, Tex.

Louisiana

HOUMA — The Southern Synthetic Co., recently organized, has plans in progress for the erection of a new local plant for the manuafcture of synthetic marble from oyster and sea shells. It is estimated to cost in excess of $45,000. Robert J. Younger and R. E. Griffing, Jr., head the company.

LAFAYETTE—The Lafayette Sugar Refining Co., New Orleans, is reported to be planning for the rebuilding of its refining plant at Lafayette, partly destroyed by fire, Oct. 12, with loss estimated at about $275,000, including machinery.

SHREVEPORT—The Caddo Cotton Oil Co. has tentative plans under consideration for the rebuilding of its local mill, destroyed by fire, Oct. 11, with loss approximately $100,000, including machinery.

NEW ORLEANS—Fire, Oct. 10, destroyed a portion of the plant of the Atlantic Paint Co., Perdido St., with loss estimated at close to $35,000, including equipment.

Maryland

BALTIMORE—The Baltimore Steel Co., Eastern Ave. and Eden St., will soon commence the erection of two 1-story plant additions, estimated to cost close to $45,000. Other buildings are planned to cost approximately $50,000. Gilbert A. Wehr is president.

BALTIMORE—The Federal Yeast Corp., Colgate Station, recently organized, has acquired the local property of the Colgate Products Co., located on Colgate Creek, for a consideration said to be $182,000. It will be used as a new plant for the manufacture of yeast products. The company is headed by Francis W. Little and Sidney A. Goodman.

BALTIMORE—Loyola College, 700 North Calvert St., has commenced foundations for a new chemistry and biology building at the institution, to be 2-story and estimated to cost close to $200,000, including equipment. Otto G. Simonson, Casualty Bldg., is architect.

Michigan

RIVER ROUGE—The Detroit Sand Lime Brick Co., 1008 Vinton Bldg., Detroit, will soon commence the erection of its proposed new plant, on site acquired a number of months ago, estimated to cost close to $100,000, including equipment.

Missouri

KANSAS CITY—The Great Eastern Mills Co., 440 7th Ave., Pittsburgh, Pa., has leased a local building at 1222 West 9th St. for the establishment of a new branch mill for the manufacture of sugar. Machinery will be installed at once.

CARROLLTON—The Sinclair Consolidated Oil Co. is planning for improvements in its local plant. New power equipment and other machinery will be installed.

JOPLIN—The Osborn Paper Co. is planning for the erection of a new 2-story building, to cost about $37,000. Plans will be drawn at an early date.

Mississippi

MOSS POINT—The Southern Paper Co. has plans in progress for extensions in its plant, to include a new paper and pulp mill, to increase the output to about 100 tons a day. A new power house will be built. E. H. Mayo is general manager.

Montana

NEIHART—The new local concentrating mill of the American Zinc & Lead Co., for which a building contract recently was awarded, will have an initial capacity of about 450 tons daily. It will handle silver, lead and copper from the company's properties in the Silver Dike district in this section. The company is making extensions in its zinc oxide operations, and plans for enlargements in its plant devoted to this production at Hillsboro, to provide a total furnace output from all plants of close to 20,000 tons of lead-free material per annum.

New Jersey

CAMDEN—Fire, Oct. 20, destroyed a portion of the plant of J. Eavenson & Son, Penn St. and the Delaware River, manufacturers of soap products, with loss estimated at close to $375,000, including machinery. It is planned to rebuild in the near future.

LAMBERTVILLE—The Jeperson Newsprint Co., South Union St., is reported to be considering plans for the rebuilding of its local mill, devoted to the manufacture of newsprint papers, partly destroyed by fire, Oct. 20, with loss estimated at close to $300,000. The mill was formerly the property of the Perservance Paper Co., and secured by the Jeperson company several months ago. It has only lately been established and operated. Henry Weeks is general manager.

LAMBERTVILLE—The Lambertville Rubber Co. is perfecting plans for plant expansion to increase the present capacity. Additions will be made in the working force..

SALEM—The Salem Glass Works, Inc., is planning for the immediate rebuilding of the portion of its plant destroyed by fire, Oct. 17. Temporary structures will be erected pending the construction of permanent buildings. The company specializes in the production of glass bottles and jars.

New York

LONG ISLAND CITY—The Liberty Paint Co., 39 10th St., has awarded a general contract to the Commonwealth Engineering Co., 103 Park Ave., New York, for the erection of a 2-story plant, 100x100 ft., on Vernon Ave., near 10th St., estimated to cost about $50,000.

JAMAICA—The Bliss Waterproof Concrete Block Co., 34 Union Hall St., has plans in progress for the erection of a new 1-story plant, 100x200 ft., at Foley and Carroll Sts., estimated to cost approximately $50,000. H. T. Jeffrey, Jr., 308 Fulton St., Jamaica, is architect.

BUFFALO—The Iroquois Natural Gas Co., Iroquois Bldg., has plans nearing completion for the construction of a new 1-story regulator building at 338 Bailey Ave., with installation to include regulators, valves, piping, etc.

BROOKLYN—The Industrial Alcohol Mfg. Co., 90 Wall St., New York, has awarded a general contract to the William Kennedy Construction Co., 215 Montague St., Brooklyn for the erection of a new 2-story plant, 50x92 ft., at 9th and Henry Sts. Work will be placed under way at once.

Pennsylvania

CHESTER—The Stauffer Chemical Co., 624 California St., San Francisco, Calif., has acquired a local tract of land, about 10 acres, heretofore held by the Dantziger Paraffin Co. of America, as a site for an Eastern branch plant. Plans will be prepared at an early date for the initial plant unit, comprising a number of buildings, estimated to cost in excess of $100,000.

LANCASTER—The Burnham Boiler Works, Inc., Ave. A, Irvington-on-Hudson, N. Y., will commence the immediate erection of a new 1-story foundry on the Dillville Rd., to be used in connection with its proposed plant here. The entire works will cost close to $200,000, with equipment. Frank D. Chase, Inc., 645 North Michigan Ave., Chicago, Ill., is engineer.

BLOOMSBURG—Fire, Oct. 13, destroyed the local plant of the Bloomsburg Paper Co., with loss estimated close to $75,000. It is expected to rebuild.

ORVISTON—The Central Refractory Co., Newark, O., has acquired the local plant and property of the Center Brick & Clay Co., with firebrick works at Snow Shoe, near Orviston, and large fireclay deposits in Clinton County. The new owner will continue operations, and purposes making a number of extensions and improvements.

JACOBS CREEK—The S. A. Drug & Chemical Co. is taking bids on a general contract for the construction of a new plant on local site, to cost about $150,000, including machinery. Peter Rosello, 406 Congress Bldg., Detroit, Mich., is the architect. S. J. Ferguson is in charge of company operations.

HUNTINGDON—A portion of the foundry at the plant of the Extension Radiator Works was destroyed by fire, Oct. 18, with loss estimated at about $25,000. The company is operated by the Pierce, Butler & Pierce Mfg. Corp., Syracuse, N. Y.

Tennessee

CHATTANOOGA—The Southern Sheet Steel Co., recently organized with a capital of $1,100,000, has tentative plans under way for the erection of a new plant on local site, consisting of three 60-ton open-hearth furnaces, sheet mill and other buildings, estimated to cost in excess of $400,000, including equipment. W. M. Blecker is president, and W. J. Lynch, vice-president and general manager.

CHATTANOOGA—The Rabe Pipe & Foundry Co., North St. Elmo, Chattanooga, has plans under way for the erection of a new 1-story foundry, 100x150 ft., to be equipped for the most part for the manufacture of iron castings. R. R. Rabe is president and general manager.

Texas

HOUSTON—Walter D. Rogers, 708 Clark St., is organizing a company to establish and operate a local plant for the manufacture of seamless rubber products and other rubber goods. A list of equipment to be installed will be arranged at an early date to include ovens, dipping and forming, machinery, drying equipment, etc.

GORMAN—The Eastland County Gasoline Co., recently organized with a capital of $105,000, has plans in progress for the erection of a 3-unit refining plant, with initial capacity of about 5,000 gal. per day, estimated to cost approximately $80,000. The installation will comprise compressors, high and low pressure pumping machinery, tills, etc. J. T. Purdy heads the company.

OILTON—The Magnolia Petroleum Co., Houston, has plans in progress for the construction of a new storage and distributing plant on local site, estimated to cost in excess of $250,000, The plant will handle the output from the company's property in the Webb-Zapata oilfields.

ROBSTOWN—W. C. Craig, Brownsville, Tex., is organizing a company to construct and operate a local plant for the manufacture of brick, tile and other burned clay products. A site has been selected and work will be placed under way at an early date

Virginia

ROANOKE—J. W. Simpkins, Roanoke, has acquired mica properties in Patrick County totaling about 70 acres. Plans are being formulated for the organization of a company to develop the lands, and establish and operate a complete mill for pulverizing and other service for commercial production.

RICHMOND—The Fiber Board Container Co., manufacturer of fiber products, is planning for the rebuilding of the portion of its plant recently destroyed by fire with loss estimated at close to $100,000, including machinery.

Capital Increases, etc.

THE PENNSYLVANIA INDEPENDENT OIL CO., Allentown, Pa., has filed notice of increase in capital from $200,000 to $1,000,000.

THE SOUTHERN CLAY MFG. CO., Chattanooga, Tenn., has filed notice of increase in capital from $300,000 to $1,000,000, for proposed expansion.

THE INDEPENDENT PAPER MILLS, INC., 68 5th St., Brooklyn, N. Y., has filed notice of increase in capital from $100,000 to 200,000.

THE SINCLAIR CONSOLIDATED OIL CORP., 45 Nassau St., New York, N. Y., has arranged for a preferred stock issue of $45,000,000, a portion of the proceeds to be used for improvements and expansion.

THE EBSARY GYPSUM CO., 140 West 42nd St., New York, N. Y., has been increased in capitalization from $40,000 to $80,000, for proposed expansion.

THE BRADSTREET & BRADEN CO. OF DELAWARE, Oklahoma City, Okla., manufacturer of oil products, has filed notice of increase in capital from $65,000 to $100,000.

THE CONSOLIDATED COPPER MINES CO., 120 Broadway, New York, N. Y., has been reorganized, with plant and properties turned over to a new corporation to be known as the Consolidated Copper Mines Corp. William W. Mein is president, and Howard D. Smith, vice-president.

THE INTERCONTINENTAL RUBBER CO., George H. Carnahan, 120 Broadway, New York, N. Y., president, recently reorganized, is arranging for an issue of $2,903,000 in notes, of which $290,300 will be used for expansion and additional working capital.

THE MAMMOTH OIL CO., New York, affiliated with the Sinclair Consolidated Oil Corp., 45 Nassau St., has arranged for a stock issue in excess of $10,000,000, a portion of the proceeds to be used for the development and equipment of oil properties in the Teapot Dome district, Wyo.

New Companies

PETERS & RUSSELL, INC., Boston, Mass., has been incorporated with a capital of $50,000, to manufacture abrasive materials, grinding wheels, etc. Paul S. Peters is president, and Frank H. Russell, 75 Park St., West Roxbury, Mass., treasurer.

THE FINISHING SPECIALTIES & SERVICE CO., 4054 Greenview Ave., Chicago, Ill., has been incorporated with a capital of $25,000, and 250 shares of stock, no par value, to manufacture enamels, varnishes, etc. J. I. and Fred W. McClement, and Philip W. Carston are the incorporators.

THE ROSEBRAND CO., Atlantic City, N. J., care of Joseph B. Perskie, 513 Guarantee Trust Bldg., Atlantic City, representative, has been incorporated with a capital of $125,000, to manufacture chemicals and chemical byproducts. The incorporators are E. and Harold A. Brand, and Louis Rosenthal.

THE JOHN BRUNO CO., New York, N. Y., care of J. A. O'Brien, 1402 Broadway, representative, has been incorporated with a capital of $20,000, to manufacture polishing oils and kindred products. The incorporators are J. B. H. Guest, and H. Markowitz.

E. M. AND F. WALDO, INC., 904-7 Maryland Trust Bldg., Baltimore, Md., has been incorporated with a capital of $500,000, to manufacture chemicals, paints, pigments and affiliated specialties. The incorporators are Edward M. and Frank Waldo.

THE LAVEX CHEMICAL CO., Kansas City, Mo., has been incorporated with a capital of $50,000, to manufacture chemicals and chemical byproducts. The incorporators are Reynold and O. E. Barnum and W. R. Smith, all of Kansas City.

THE NATIONAL MOTOR CASTINGS CO., South Haven, Mich., has been incorporated with a capital of $250,000, to manufacture iron, steel and other metal castings. The incorporators are F. H. Gallagher, G. H. Wisting and R. B. Campbell, all of South Haven.

THE AIRTITE PAINT CORP., New York, N. Y., care of Avery & Whiting, 5 Nassau St., representatives, has been incorporated with a capital of $10,000, to manufacture paints, varnishes, etc. The incorporators are J. E. Whiting, E. B. Bender and G. O. Castell.

THE REX CHEMICAL CO., Houston, Tex., has been incorporated with a capital of $8,000, to manufacture chemicals and chemical byproducts. The incorporators are W. D. Plunkett, L. J. Jones and W. H. Schopmeyer, all of Houston.

THE EASTERN CHEMICAL CO., 75 Elmdale Ave., Providence, R. I., has filed notice of organization to manufacture chemical products. The company is headed by A. J. Kechigian.

THE H. H. ALLYN RUBBER CORP., Philadelphia, Pa., care of the Corporation Guarantee & Trust Co., Land Title Bldg., Philadelphia, representative, has been incorporated under Delaware laws, with a capital of $100,000, to manufacture rubber products, automobile tires, etc.

THE PEERLESS PRODUCTS CO., First St., Mt. Washington, Baltimore, Md., has been incorporated with a capital of $100,000, to manufacture varnishes, paints, and kindred products. The incorporators are Charles J. Harris, Floyd T. Macgill and Norman R. Eckard.

THE ACKERMITE CO. OF AMERICA, 130 North Wells St., Chicago, Ill., has been incorporated with a capital of 30 shares of stock, no par value, to manufacture chemicals, special metals, etc. The incorporators are Randolph Thornton, H Baar and Walter H. Eckert.

THE HARLEM CHEMICAL CORP., care of the Corporation Registry Co., 900 Market St., Wilmington, Del., has been incorporated under Delaware laws, with capital of $500,000, to manufacture chemicals and chemical byproducts.

THE BRASS FOUNDRY CORP., New York, N. Y., care of William Karlin, 132 Nassau St., has been incorporated with a capital of $15,000, to manufacture brass, bronze and other metal castings. The incorporators are L. Stein, J. Schlachter and J. Safer.

THE VALERICINE CHEMICAL CO., Boston, Mass., has filed notice of organization to manufacture chemical specialties. The company is headed by Fred Merrill Drake, 117 Arlington St., Hyde Park, Boston.

THE CHEMICAL PRODUCTS CO., East Chicago, Ind., has been incorporated with a capital of $5,000, to manufacture chemicals and chemical byproducts. The corporators are Marris M., David and S. V. Milgram, all of East Chicago.

THE GRANT PAINT PIGMENT CO., Bensonville, Ill., has been incorporated with a capital of $50,000, to manufacture paint pigments, coloring products, etc. The incorporators are Max Grant and Frank S. Robins. The company representative is Bucklan & Scheuneman, Conway Bldg., Chicago, Ill.

THE BUCKEYE OIL & GREASE CO., Canton, O., has been incorporated with a capital of $25,000, to manufacture oils, greases and kindred products. The incorporators are Elbert J. Smith and David D. Herr.

THE ESSEX TILE CRAFT, INC., Newark, N. J., has been incorporated with a capital of $50,000, to manufacture ceramic tile and kindred products. The incorporators are Leo E. Goddu, L. and William G. Anderson, 241 Summer Ave. The last noted represents the company.

THE NEW ERA CHEMICAL MFG. CO., 416 Belvedere Ave., Baltimore, Md., has been incorporated with a capital of $100,000, to manufacture chemicals, alkalis, etc. The incorporators are R. E. Lee Young, Richard E. Preece and William M. Travers.

THE FEDERAL ALLOY STEEL CORP., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated with a capital of $12,000,000, to manufacture steel and steel alloy products.

THE INTERNATIONAL PAINT CORP., 1214 Walnut Ave., East St. Louis, Ill., has been incorporated with a capital of $50,000, to manufacture paints, linseed oil, white lead and kindred products. The incorporators are H. F. Dreimeyer, C. Pope and C. E. Altrogge.

F. W. WEBER & CO., INC., Keyport, N. J., has been incorporated with a capital of $50,000, to manufacture chemical products. The incorporators are Caspar O. Manx and F. W. Weber, Keyport. The last noted represents the company.

THE O. K. MFG. CO., Philadelphia, Pa., care of A. A. Watson, Dover, Del., representative, has been incorporated under Delaware laws, with a capital of $100,000, to manufacture cement products. The incorporators are H. P. Street, Haverford, Pa.; H. L. Maris, Penfield, Pa.; and J. C. Harrelson, Philadelphia.

THE MERION MAGNESIA CO., Phoenixville, Pa., has been incorporated with a capital of $5,000, to manufacture magnesia products. The incorporators are James Goodall, Samuel Carpenter and Clayton Ullman, 1027 West Bridge St., Phoenixville. The last noted is treasurer and represents the company.

THE PRIMROSE REFINING CO., Wichita Falls, Tex., has been incorporated with a capital of $100,000, to manufacture refined oil products. The incorporators are H. J. Stief and S. J. Brin, both of Wichita Falls.

THE ALLEGHENY CHEMICAL MFG. CO., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., has been incorporated under Delaware laws with capital of $100,000, to manufacture chemicals and chemical byproducts, waterproofing materials, etc.

THE KRASCO MFG. CO., 451 East Ohio St., Chicago, Ill., has been incorporated with a capital of 1,000 shares of stock, no par value, to manufacture metals and metal alloys. The incorporators are Eric L. Anderson, Paul N. Dale and Frank J. Dowd.

THE CORKSTONE PRODUCTS CORP., 121-23 North Collington Ave., Baltimore, Md., has been incorporated with a capital of $25,000, to manufacture oxide-chloride cement products, composition specialties, etc. The incorporators are Leon H. Grossman, I. Weinberg and Solomon C. Berenholtz.

GEORGE A. MOLLESON & CO., INC., New York, N. Y., care of C. H. Molleson, 165

Broadway, representative, has been incorporated with a capital of $50,000, to manufacture oils, greases, etc. The incorporators are G. A. and S. H. Molleson, and W. A. Bunta.

THE SNOWDRIFT SOAP CO., care of the Colonial Charter Co., Ford Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws with a capital of $250,000, to manufacture soaps, washing powders, etc.

THE INTERNATIONAL OIL CO., Lombard and 9th Sts., Baltimore, Md., has been incorporated with a capital of $100,000, to manufacture and deal in oil products. The incorporators are Morris Zemil and Louis Wolach.

Industrial Developments

GLASS—The Dunkirk Window Glass Co., Dunkirk, South Charleston, W. Va., has resumed operations at its plant after a shut-down of close to 4 months. About 200 men will be employed for the present, with early increase in working force in the future. The company is said to have orders on hand for at least 4 months continuous production.

Machine-operated window glass plants in Pennsylvania, West Virginia, Indiana and other parts of the coutnry are now running on a full 25-hour day basis giving employment to normal working forces. It is said that the demand insures production on this schedule for a number of months to come.

The United States Sheet & Window Glass Co., Shreveport, La., has placed its local plant in operation. It has recently been completed at a cost of about $1,000,000, and has provisions for a full working force of about 500 men. It is expected to advance production to this point at an early date.

LEATHER — The Griess-Pfleger Tanning Co., Natick, Mass., has advanced operations to a full production basis at its local plant.

The Ohio Leather Co., Girard, O., is running at full capacity at its local calfskin tannery, with employment of regular working force.

The Continental Leather Co., Bridesburg, Pa., has production under way on close to capacity basis at its local tannery, and carload shipments are now leading the plant.

The Lorraine Tanning Co., Peabody, Mass., formerly known as the Webber-Laemmle Tanning Co., is operating at close to normal at its tannery.

RUBBER—The Perfection Tire & Rubber Co., Fort Madison, Ia., is running on a basis of 1,200 tires a day, and will maintain this schedule for an indefinite period.

The Firestone Tire & Rubber Co., Akron, O., is planning to place its new rim plant in operation at an early date. The factory is now nearing completion and will have a rated capacity of 20,000 passenger car tire rims and 4,000 solid truck tire rims per day, said to be the largest plant of its kind in the world. A large working force will be employed.

The Seiberling Rubber Co., New Castle, Pa., is maintaining capacity production at its local plant, with full operating schedule also prevailing at its Ohio mills. Business is said to be averaging $500,000 per month.

The Kelly-Springfield Tire Co. is holding to capacity output at its Akron, O., plant, with production at the Cumberland, Md., mill at a point as high as labor supply will permit. There is said to be a scarcity of men in this section, necessitating the use of ordinary labor and giving a course of training. Current production at the plants is at a basis of 6,000 tire casings per day, with a relatively large output of tubes and solid tires.

IRON AND STEEL—The National Enameling & Stamping Co. has advanced production to close to normal at its steel sheet mills at Granite City, Ill., after a partial shut-down through the summer and early fall; 14 mills have recently been placed in service.

The Phoenix Iron Co., Phoenixille, Pa., has 5 furnaces in operation for the first time in the past 4 years. Production has been increased in the different operating departments and orders on hand insure continuance on the present basis for some time to come. The company has advanced the wages of laborers at the plant 40 cents a day, making a rate of $3.15 a day; skilled operatives have also received an increase.

The Jones & Laughlin Steel Co., Pittsburgh, Pa., has blown in the last of its Aliquippa group of blast furnaces at Woodlawn, Pa., making 11 out of 12 stacks in active operation. The last furnace, one of the Eliza group, is expected to go into blast at an early date giving 100 per cent operation for the first time in a number of months.

The Sloss-Sheffield Steel & Iron Co. has repairs under way at one of its blast furnaces at North Birmingham, Ala., requiring from 2 to 3 weeks. Shortly thereafter the unit will be blown in.

The Alan Wood Iron & Steel Co., Philadelphia, Pa., is planning to blow in its No. 3 blast furnace about the middle of November.

Steel mills at Gary, Ill., are now running on the basis of about 80 per cent of capacity, and are held at this point through labor shortage. It is said that the plants would employ at least 2,000 additional men if they were available. With the continued labor scarcity, it is said that another increase in wages likely will be made in the near future to hold present employees.

The Whitaker-Glessner Co. is running under heavy output at its hot mills at the Wheeling and Beech Bottom, W. Va., and Martins Ferry, O., plants. The wages of employees have recently been advanced 10 per cent.

The Falcon Steel Co., Niles, O., is said to be planning for the early resumption of operations at four of its sheet mills, recently closed down on account of car shortage.

METALS—The Eagle-Picher Lead Co., has advanced operations to a full capacity basis at its Henryetta, Okla., smelting plant, with day and night shifts. Five roasters and 6 blocks are in service.

The Success Mining Co., Wallace, Idaho, is advancing production at its local concentrating mill, and it is expected to give employment to 3 operating shifts at an early date. Production is devoted to lead and zinc, with small silver showings.

The Butte & Superior Co., Butte, Mont., is increasing production at its properties and is now shipping on a basis of 8,000,000 lbs. of concentrates a month to the zinc electrolytic plant of the Anaconda Copper Mining Co., at Great Falls, Mont.

The National Cast Iron Pipe Co., Birmingham, Ala., is arranging to increase operations about 50 per cent at its plant, including the installation of considerable special equipment.

The Bunker Hill & Sullivan Mining Co., Kellogg, Idaho, has blown in the second furnace at its local smelting plant, and plans to operate on the present basis for an indefinite period.

MISCELLANEOUS—The Hudsondale Ochre Works, Hudsondale, Pa., is planning for the early resumption of operations at its local plant, following a suspension caused by car shortage.

The Dill & Collins Co., Philadelphia, Pa., manufacturer of paper, is running on a 24-hour day working schedule at its local mills. It is planned to continue on this basis for an indefinite period.

The Sapulpa Refining Co., Sapulpa, Okla., is operating its local oil refinery on a basis of 5,000 bbl. per day. The plant has a rated output of 7,000 bbl., and it is planned to advance production in the near future.

The Diamond State Fiber Co., Bridgeport, Pa., is maintaining operations on a full-capacity schedule at its local plant, with employment of regular working force. An increase has recently been made in the wages of skilled operatives and laborers, ranging from 2 to 5 cents per hour.

New Publications

NEW U. S. GEOLOGICAL SURVEY PUBLICATIONS: Mineral Resources of the United States in 1921 (preliminary summary), introduction by G. F. Loughlin and statistics assembled by Martha B. Clark, published Sept. 14, 1922; I: 7, Manganese and Manganiferous Ores in 1921, by H. A. C. Jenison (Mineral Resources of the U. S., 1921, Part I), published July 8, 1922; I: 8, Lead and Zinc Pigments and Salts in 1921, by C. E. Siebenthal and A. Stoll (Mineral Resources of the United States, 1921, Part I), published July 10, 1922; I: 9, Bauxite and Aluminum in 1921, by James M. Hill (Mineral Resources of the United States, 1921, Part I), published Aug. 1, 1922; II: 7, Salt in 1921, by G. F. Loughlin and A. T. Coons (Mineral Resources of the U. S., 1921, Part II), published June 29, 1922; II: 8, Strontium in 1921, by George W. Stose (Mineral Resources of the U. S., 1921, Part II), published July 5, 1922; II: 9, Carbon Black Produced From Natural Gas in 1921, by E. G. Sievers (Mineral Resources of the U. S., 1921, Part II), published July 5, 1922; II: 10, Fluorspar and Cryolite in 1921, by Hubert W. Davis (Mineral Resources of the United States, 1921, Part II), published July 6, 1922; II: 11, Potash in 1921, by M. R. Nourse (Mineral Resources of the U. S., 1921, Part II published July 10, 1922; II: 12, Phosphate Rock in 1921, by K. W. Cottrell (Mineral Resources of the U. S., 1921, Part II published July 11, 1922; II: 12, Asphalt and Related Bitumens in 1921, by K. W. Cottrell (Mineral Resources of the U. S., 1921, Part II), published July 26, 1922; II: 14, Mica in 1921, by B. H. Stoddard (Mineral Resources of the U. S., 1921, Part II), published Aug. 3, 1922; II: 15, Magnesite in 1915, by Charles G. Yale (Mineral Resources of the U. S., 1921, Part II published Aug. 5, 1922; II: 16, Gypsum in 1921, by K. W. Cottrell (Mineral Resources of the U. S., 1921, Part II), published Aug. 4, 1922; II: 17, Talc and Soapstone in 1921, by Edward Sampson (Mineral Resources of the U. S., 1921, Part II), published Aug. 4, 1922; II: 18, Clay in 1921 by Jefferson Middleton (Mineral Resources of the U. S., 1921, Part II), published Sept. 20, 1922; II: 19, Feldspar in 1921, by Frank J. Katz (Mineral Resources of the U. S., 1921, Part II) published Aug. 31, 1922; II: 22, Asbestos in 1921, by Edward Sampson (Mineral Resources of the U. S., 1921, Part II) published Sept. 19, 1922; II: 32, Asbestos in 1921, by Edward Sampson (Mineral Resources of the U. S., 1920, Part II), published July 7, 1922; II: 33, Clay-Working Industries, Clay and Silica Brick in 1919 and 1920, by Jefferson Middleton (Mineral Resources of the U. S., 1920, Part II) published Aug. 14, 1922.

Organic chemists will find of interest and value the recent publication of the National Research Council, entitled "Organo Magnesium Compounds in Synthetic Chemistry," "A Bibliography of the Grignard Reaction 1900 to 1921," by Clarence J. West and Henry Gilman. In addition to a comprehensive compilation of 1,485 separate references and an equally comprehensive index by compounds the bulletin contains a very interesting descriptive chapter of the Grignard reaction. Subheads in this chapter include a historical statement, the preparation of the Grignard reagent, its constitution and its reactions, and finally its use in the preparation of hydrocarbons, alcohols, ethers, aldehydes, ketones, acids, esters, nitriles and certain inorganic compounds. This bulletin is published as Reprint and Circular Series No. 24 and sells for $1.50.

Coming Meetings and Events

AMERICAN CHEMICAL SOCIETY will hold its spring meeting April 3 to 7, 1923, at New Haven, Conn.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its winter meeting at Richmond, Va., Dec. 7 to 9.

INTERNATIONAL CHAMBER OF COMMERCE will hold its second general meeting in Rome, Italy, March 19-26, 1923.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club 52 East 41st St., New York City Nov. 10—American Chemical Society (in charge), Society of Chemical Industry, American Electrochemical Society, Société de Chimie Industrielle, joint meeting. Nov. 17—American Electrochemical Society, regular meeting. Dec. 1—Society of Chemical Industry, regular meeting. Dec. 8—American Chemical Society, regular meeting. Jan. 5—American Chemical Society, regular meeting. Jan 12—Society of Chemical Industry, Perkin Medal. Feb. 9—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle. American Chemical Society, joint meeting March 9—American Chemical Society, Nichols Medal. March 23—Society of Chemical Industry, regular meeting. April 20—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting. May 4—American Chemical Society, regular meeting. May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting, May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.

erman Wages and Export Policy Retard Business Recovery

AT THE OPENING of the forty-fourth general meeting of the Society for the Protection of the Inters of the German Chemical Industry (Verein zur ahrung der Interessen der Chemischen Industrie eutschlands) in Leipzig last September, Dr. C. DUISRG, chairman, gave an address on the economic status f the German chemical industry in 1921-1922. Dr. UISBERG is the head of the famous Farbenfabriken rm. Fried. Bayer at Leverkusen and of the powerful erman chemical trust, Interessen Gemeinschaft. He , in fact, the active as well as the nominal leader of e German chemical industry. He is not a mere gurehead of the ex-Wilhelm II or Stinnes type, and ence his utterances not only carry much weight in ermany but must not be overlooked outside of that untry.

In his address Dr. DUISBERG spoke solely from the erman viewpoint and presented statements that can nly deepen the ill-feeling of the German intellectuals ward their former enemies. At the same time he did ot even remotely touch on matters that we know they ught to know. Thus he blamed the French for the resent German coal situation, when a mere analysis of fficial German figures made public April 1, 1922, will how that there is no foundation for this attitude. [is figures on comparative export values of German roducts in gold marks and paper marks are quite devoid f any units of weight or measurement that would give hem genuine value, especially when we know that erman export selling prices for the period he mentions ere only a fraction of the intrinsic value of the exported roducts. His wailing about the plight of German scienists, students and workmen presents the true situation, ust as true as the absence of German research, which e also bemoans.

But he does not mention the fact that all of these egrettable conditions are the inevitable result of the xploiting policy of industrials like himself, who pay heir workmen abnormally low wages and dump the roducts of their work at prices far below their inrinsic value.

The remedies he suggests, in addition to the everxed idea of the abrogation of the treaty of Versailles, re more work, more export and less import. But these re mere words, because no one knows better than e that this has been Germany's policy ever since the rmistice. What good can be accomplished by such a olicy as long as labor is remunerated with only a raction of its due reward and export prices are far elow the intrinsic value of the products?

It is high time for German industrials of the Duiserg type to inaugurate a policy that will prove to be genuine remedy—namely, the payment of wages ompatible with the honest due of the workmen and the ale of their products at prices commensurate with their intrinsic value. It is idle merely to repeat over and over again the present plight of the Germans. They must go to the root of the trouble and eradicate the cause which, besides sapping the vitality of the masses by undernourishment and mental discontent, is gradually bringing the country to the brink of irremediable weakness.

Honest work and honest competition should be the slogan of the German industrials, and it is incumbent upon men like Dr. DUISBERG to lead in this direction.

It may be set down as fundamental in the restoration of normal industrial conditions in Germany that the German workman must be honestly paid for his work.

Strikes and the Public's Rights

IT IS specious reasoning that couples "the right to strike," as a general principle, with "human liberty" and the impropriety of "compelling any man to work against his will." The right to strike, as supported either by law, by ethics or by the public conscience, is merely the right of collective bargaining, granted for the purpose of placing employees on equal terms with employers. Human liberty requires that the employee be at no disadvantage.

But when a strike is directed against the general public, or when the general public is seriously affected by it, an entirely different case is presented. The difference is illustrated by the recognized illegality of the secondary boycott. That illegality rests upon the fact that the secondary boycott seeks to get a third party to enter a dispute between the two original parties.

That strikes, as we have been having them lately, work an injury to the general public is already well recognized. Remedy is another matter, for means must be developed. Even if a suitable remedy were fully and clearly formulated, however, there would still have to be a much stronger public sentiment than now exists in order to make it effective. The inherent difficulty is that majorities feel that their interests will naturally be taken care of, while minorities realize that they must organize and fight. The general public does not realize how much it has lost by the recent coal strike. It comforts itself in paying present coal prices by reflecting that they might be higher still, largely overlooking the fact that the price for bituminous is about double that ruling before the strike. It looks as if the United Mine Workers had obtained a large advance in wages, when what really happened was that the operators lost in their effort to reduce wages.

The public can formulate a doctrine that it will protect workmen to the extent of seeing that they are placed upon equal bargaining terms with their employers. But it will certainly deny that they have a right to be stronger than their employers, just as it has refused to support a system that would make the em-

ployers stronger than their employees. At the same time it must insist that the parties do not get into a dispute that will be inimical to the general welfare. This is no unreasonable bill of rights for the public to adopt. What is needed is a crystallization of sentiment and a recognition of the fact that the majority needs to be organized and articulate.

Enlightened Conduct Of Corporations

WE HAVE lately observed a great combination of manufacturers of chemicals, the principal figure in which is said to have felt that the separate concerns did not avail themselves of all the profits which the market afforded. But we are reminded that the U. S. Steel Corporation saved itself from the charge of monopoly by this very apparent fault. In an article on "The Revival of Mergers," by J. BARTON NEALY in *The World's Work* for October, he says of the Steel Corporation: "In times of prosperity it sold at a uniformly low price, satisfied with a fair return, while its competitors charged all the traffic would bear. In times of depression it became one of the country's most stabilizing influences, spending millions in expansion to maintain employment, extending millions in credit, both here and abroad, thereby retaining its foreign and domestic trade, and last, but not least, loaned millions in the open market to those less fortunate." Under less enlightened administration of the corporation there would have been far greater dividends, but the company would have been disbanded.

Let us cite another example of what our old friends Uncle Dan'l Dollardoodle and Mr. Quickturn Capital would probably call the silly foolishness of the Standard Oil Co. We quote from a letter of the late Lord NORTHCLIFFE to the late WALTER H. PAGE. The letter was dated Manchester-by-the-Sea, Mass., Aug. 13, 1917:

> In great privacy let me tell you of an enormous responsibility that was placed on my shoulders one midnight, in the form of a desperate cable from A. J. B. (Mr. BALFOUR) as to the immediate putting of our fleet out of action owing to an apparently suddenly discovered great shortage of oil. I had been here only a few days, but long enough to know that such fuel was already scarce here. I knew that such a cable, if disclosed, could cause such a jump in the oil market as had never been known. I was up bright and early, I can assure you. A little cautious pussyfooting as to the oil fuel situation brought no comfort—great demand, small supply—nothing doing. I read and re-read that telegram, and finally called up the Standard Oil head man. We met, and I gave him the cable to read, despite its "*Most Urgent Most Secret*" inscription. He read it slowly twice, gave it back to me, saying, "If it can be done, it will be done." I said nothing whatever about price. Those people started right in there, and oil is pouring across the Atlantic with giant strides and at a lower price than we have averaged over here. They could have squeezed millions out of our trouble, if they had chosen. When I thanked them they merely remarked, "It's our war as well as yours."

These are obligations that the purely commercial mind cannot see. Such acts cost money and "waste" dividends. And yet the old captains of industry who direct the affairs of these corporations have learned from experience that a corporation is a thing with obligations and duties that cannot be found in any book of rules that may be compended. It is difficult for the speculator to learn this, and indeed some manufacturers never learn it. The bigger a corporation is the harder it is to practice it, and yet that very human quality is necessary to long-abiding and eventual success. Failure to attain it may encourage quick profits, but it also instigates slow death.

Cementing Anglo-American Friendship and Unity

FRESH impetus was given last month to the cau of Anglo-American friendship and unity by tl visit to the United States of a group of editors ar publishers of English business and technical paper They came as delegates to the annual meetings of th Associated Business Papers, Inc., and the Nation Conference of Business Paper Editors. In additio to participating in the sessions of these two organiz tions and exchanging views on publishing and editori problems, they subsequently visited appropriate indu trial centers and gathered impressions of business an economic conditions in this country. In the short tim at their disposal they doubtless saw so much and i such rapid succession that their impressions resemble nothing so much as the striking but fleeting pattern of a kaleidoscope. But out of it all there crystallize certain general views in the minds of our visitors tha must inevitably make for a better understanding i England of some American problems and conditions.

Prominent among the British visitors was F. H HAMER, editor of *The Chemical Age*, London, who, w are happy to say, was a most creditable representativ of British chemical industry as well as its technica press. In the Chemists' Club, where he resided durin his stay, he proved himself a delightful companion, an on several occasions demonstrated his capacity as forceful and well-informed speaker.

The note of Anglo-American friendship that h sounded in his speech at the banquet of the Associate Business Papers and which was reflected also in mes sages that he brought from Lord RIDDLE, Earl BALFOUR Lord ROBERT CECIL, Viscount BURNHAM, Sir ERNES BENN, Sir WILLIAM BERRY and C. P. SCOTT, editor o the Manchester *Guardian*, gave additional evidence o the spirit of harmony prevailing among the leaders o thought in the two nations. Mr. HAMER'S own impres sions of the United States, penned briefly before h sailed and published elsewhere in this issue, will b read with no little gratification by chemists on both sides of the Atlantic.

Proposing a Chemical Exposition Course of Study

AMONG the recognized purposes of the Chemical Ex position as it has been conducted for the past 8 years, is that of educating not only the public to a appreciation of the value of chemistry in our nationa life but also students of chemical engineering and indus trial chemistry who are still in their undergraduat years. No doubt both these classes have been benefited in large measure as a result of the efforts that have been made in their behalf, but it begins to look a though a great opportunity for service has been over looked in connection with the student group.

The particular attention of teachers of industria chemistry and chemical engineering is directed to a communication in this issue from Prof. W. T. READ, o the Sheffield Scientific School of Yale University, i which he outlines a plan followed with undergraduat students of chemistry for the past 3 years. He has made use of the Chemical Exposition as a vast labora tory for instruction in chemical equipment and funda mental processes. The success of his work has been s striking that the annual visit to the exposition has be come a requirement in Sheffield courses in industria chemistry and chemical engineering.

But this is not enough. As Professor READ point

ct, the plan is capable of extension by simply multiplying the number of institutions participating. If this ere accomplished, however, it would be necessary to ganize the work thoroughly so that there would be duplication of work and no conflict of groups of udents going unsystematically about the exposition. e think we can see in Professor READ'S suggestion the ssibility of organizing a one week's course at the position for students from nearby colleges and univerties. Arrangements could be made with specialists for tures on fundamental processes, and such lectures uld be supplemented by explanation at the booths of pical apparatus on exhibition. Professors in charge the different groups of students could hold their own tures and quiz sections and use their own devices r making the most out of the week's study.

The exposition management has here an exceptional portunity to render service of immeasurable value. e suggest that an impartial committee be appointed draft a tentative schedule of lectures and systematic spection of exhibits, and submit the plan to professors colleges within a radius of a few hundred miles of ew York, soliciting their co-operation. With this as a ucleus it will be possible to evolve an excellent course; nd if a high standard is maintained in the selection of cturers and if the attending professors make the most the exhibits, we think that the annual "Chemical xposition Course" will become a popular requirement universities that are close enough to New York to ail themselves of it.

hat Is Steel?

THAT question ought to be easy to answer. We have a very large and very authoritative dictionary and e shall go to it. It says:

> Steel. A variety of iron intermediate between cast iron and wrought iron, very tough and, when tempered, hard and elastic.

Evidently, to understand this, we shall also have to ok up two more definitions.

> Cast Iron. The direct product of the blast furnace or of the cupola, fusible and brittle. It can be tempered, but not welded or forged.
>
> Wrought iron. The purest form of iron commonly known in the arts, containing only about half of one per cent of carbon. It is tough, malleable and ductile.

It's pretty difficult to strike a position "intermediate" tween these two definitions, except for carbon content, nce the terms used to describe the properties are lative. As a matter of fact, cast iron usually contains to 4 per cent of carbon, steel anywhere from 0.1 1.4 per cent, and wrought iron is quite low in carbon .05 per cent, rarely going higher than 0.25).

But how about the ordinary physical properties? rom a recent textbook on strength of materials we nd the following data:

	Gray Cast Iron	0.4 Steel (Hot-Rolled)	Wrought Iron
nsile strength	26,000	85,000	50,000
eduction in area....	Very low	43	30
rinell hardness	150	165	85

Evidently this particular steel is not intermediate in rength, ductility or hardness; it is intermediate only its chemical composition. The dictionary definition scarcely satisfactory.

Now turn to the steel makers, who certainly ought to e able to recognize their product. Dr. JOHN A. ATHEWS recently commented on the fact that steel has ten been defined as the product of certain commercial anufacturing processes. But that leads to an argument every time a new process is discovered—can its products be called steel truthfully? Since his corporation makes steel by various methods, he should be free of prejudice toward a definition by method, and he says: "Steel of commerce is that form of iron which has been produced by melting to yield a finished product which is malleable." That is, malleability must be possessed by a metal before it can be called steel.

This definition (and that which may be discovered hidden among seven pages of qualifications in Dr. HENRY M. HOWE'S last book) includes the open-hearth product which contains not more than 0.01 per cent carbon. It takes little account of ancient usage, deep rooted in metallurgical lingo, that steel is a kind of iron *which will harden*, and as far as modern research has enabled us to understand the true mechanism of hardening by heat-treatment, it is necessary that the iron be alloyed with at least a little carbon before it will harden upon quenching. It seems illogical to call the purest iron of commerce—an iron much purer than wrought iron—a steel simply because it was tapped molten from a furnace. As it comes spouting into the ladle, a casual observer could not tell it from a carbon steel, but in the ingot and forever after it can easily be distinguished.

Is it not time to permit our definitions to be illuminated by the great light of metallography? Why not recognize that steel is an alloy of iron and iron carbide? Ah, yes, you will object, but where is the dividing line; if the stuff contains 0.01 carbon is it iron or is it steel? Or is the boundary 0.025 per cent?

As a matter of fact, it is not necessary to split hairs so fine as that. In commercially pure iron all impurities total 0.05 per cent or less. On the other hand, dead soft rivet steel from the converter contains a lot of gas and a total of 0.10 per cent or more impurities found by analysis; but to bring this metal to workable form carbon must be increased to 0.08 per cent and other elements (mostly deoxidizers) to a total of 0.35 per cent or more. In other words, the purest, softest steel of commerce contains nine times as much impurity as commercially pure iron. A man with a microscope need never confuse wrought iron with either.

Steel is a malleable alloy of ferrite and cementite. The definition includes all varieties from low to highest carbons, and differentiates them neatly from cast irons and pig irons—gray cast iron contains graphite and is not malleable; while white cast iron may contain iron carbide and be free of graphite, it is not malleable; and lastly annealed cast irons may be malleable, but they contain most of the carbon as graphite. Of course steels may easily lose their malleability by quenching; on the other hand, they are malleable when cast or can be remade malleable by the proper heat-treatment. By heat-treatment the iron carbide may also be suppressed, almost seem to be destroyed, yet it may again be regenerated and always returns as cementite and not as graphite. In alloy steels the ferrite is not pure iron, but often contains most of the added element in solid solution; the cementite may also be a complex carbide —in some cases there may be more than one carbide distinguishable under the microscope. Yet the most complex alloy steel is essentially of ferrite and cementite. Nor is there any doubt that austenitic steels (such as high-manganese steels) would break up into these constituents under a correct conjunction of temperature, pressure and time.

Many adjectives may qualify the word, noting its principal impurity or alloy, its method of manufacture, its heat-treatment, its use or its maker, but essentially, "Steel is a malleable alloy of iron and iron carbide."

Readers' Views and Comments

Students at the Chemical Exposition

To the Editor of Chemical & Metallurgical Engineering

SIR:—For a number of years the Sheffield Scientific School of Yale University has given a special summer course to all engineering students. The civil engineers go to a camp, while the mechanical, electrical and metallurgical engineers visit power plants, foundries and machine shops. When the course in industrial and engineering chemistry was established at Yale, in 1919, it was arranged that students in this course should also take summer work along with other engineering groups. It was first proposed that part of their time be devoted to visiting chemical plants. This portion of the work was assigned to me. Noting that the week in which I was to have charge of this group of men coincided with the time of the Sixth National Exposition of Chemical Industries in September, 1920, I made the request that I be permitted to take my class to New York to attend the exposition, supplementing, if necessary, with plant trips in the limits of Greater New York. Prof. T. B. Johnson, director of the Sheffield Chemical Laboratory, agreed heartily with this suggestion, but felt that the exposition would be sufficient in itself. Experience has shown this to be entirely true.

After two days in New Haven given to lecture and sketching periods, the class of 1922 in industrial and engineering chemistry was brought to the exposition for three days' work, followed by a final examination. Our experience was so pleasant and so satisfactory that this visit has been made a permanency. I have recently concluded the third of these courses, devoted mainly to chemical apparatus of manufacturing size. More than sixty men have taken this course in three years. In the past two years the students have spend the entire week in New York, lectures being given in the morning and the afternoons being devoted to visits to the various booths and study of the apparatus and machinery there shown. We have been treated with the utmost consideration and courtesy both by the management and the exhibitors. In my opinion and in the opinion of the entire faculty of the department of chemistry of Yale, this plan has been an unqualified and complete success. Not only do our students gain a conception of the construction and operation of chemical apparatus but they are infinitely more benefited by the revelation of the vast scope and power of the chemical industry and by the inspiration and vision which could not possibly be gained any other way.

The wish has been expressed that other universities might take advantage of this opportunity to send their classes to the exposition as a part of the required work in chemical engineering, and the suggestion has been made that experts in each line could be induced to talk to the collected groups of students. I wish to indorse this plan and express the hope that it may be realized. I am sure that all this could be arranged. Headquarters could be established in a booth devoted to visiting university and college students. Catalogs and trade literature could be filed under proper classifications: photographs and drawings could be mounted for easy accessibility; and the various exhibits could be cross-indexed in such a way that students could find mos easily all the things they needed to see. If there wer groups of different advancement, proper divisions coul be made, so that students seeing heavy apparatus fo the first time could be taught separately from thos already familiar with the basic principles of such ap paratus, leaving them opportunity to study details improvements and new developments.

A wise choice of experts, whose principal object woul be instruction rather than sales talk, would give thes college students a corps of teachers, authorities i their special subjects, that could not be equaled. In stead of our small group from Yale and men fron Columbia and other New York institutions who nov come independently, there is no reason why hundred of students from all over the United States could not b drawn to the most instructive week of training eve given to college men.

Speaking for myself and for Yale, I am only too gla to pledge our time and efforts to such a movement.

Personally and in behalf of my students and of Yal University, I desire to express thanks and appreciatio for the uniform kindness and courtesy we met on ever hand, and most of all for the splendid opportunity t see and appreciate the chemical industry of the Unite States.

W. T. READ.

New Haven, Conn.

Black Fractures in Carbon Tool Steels

To the Editor of Chemical & Metallurgical Engineering

SIR:—In your journal for Aug. 9, 1922 (vol. 27, p 265) Arthur W. F. Green has directed the attention o readers to an interesting phenomenon regarding black fractures sometimes observable in carbon tool steels.

The present writer considers that black fracture owe their origin to the segregation of the impurities i the ingot. According to the theory of graphitization advanced by Dr. T. Murakami and myself, graphitiza tion is not caused by the direct decomposition o cementite into ferrite and graphite, but is due to a catalytic action of carbon monoxide or dioxide.

In steel ingots, segregation is always formed in por tions somewhat inside the surface, but not in thei central portion, where the cooling is uniform. In square ingots, the segregation is found in the transverse sec tion as a square zone parallel to the sectional form, it corners being rounded. During the forging of th ingot into a circular rod or a billet, the segregated por tion may preserve its original form. By a prolonge heating, the graphitization takes place by the catalyti action of carbon monoxide or dioxide in portions where such gases are concentrated to a considerable extent the oxides which are favorable for graphitization[1] ar also found in these portions. Hence the graphitizatio begins in the segregated portion and gradually extend outward and inward, thus increasing graphitized area If the above view be correct, black fractures can b avoided, if the segregation be absent or very slight

[1] *Science Reports*, vol. 10 (1921), p. 273.

That black areas have never been noted except in steel after it had been annealed shows that the graphitization took place during the prolonged annealing; the spheroidization of cementite has no direct connection with the graphitization, indicating only that the heating interval was sufficiently long. Even in black areas, some cementite still remains undecomposed; this cementite, as well as some of the decomposed graphite, especially fine graphite particles, dissolves at the A_1 point in ferrite. Hence it is easily understood that thermal curves for black portions show no abnormality, and that the black portion can equally well be hardened by quenching. The fact that annealing of the quenched specimen (which was originally black) at a temperature a little below its critical point for 2 hours restores its original black fracture indicates that the cause of the graphitization—that is, the segregation—does not disappear by quenching. This is as would be expected.

The above explanations are given by way of examples, but other facts as enumerated by Mr. Green are satisfactorily explained by the above view.

Sendai, Japan. KOTARO HONDA.

A British Editor's Impressions of the United States

By FREDERICK E. HAMER
Editor, *Chemical Age*, London

MY FRIEND the editor of *Chemical & Metallurgical Engineering* has asked me to set down some impressions of American industrial conditions gained during a stay of 4 weeks in the United States as a delegate from the Weekly Newspaper Proprietors Association of London to the Associated Business Papers, Inc., of America. It is inevitable that one's observations should be more or less superficial in such circumstances; at the same time, on the principle that the spectator sometimes sees most of the game, they may be worth recording.

Unity of Types and Similarity of Problems

My chief and most lasting impression is one of the essential unity between the British and American types of character and of the similarity between the industrial and economic conditions and problems in both countries. An Englishman visiting the other European countries—Germany, Italy, Switzerland, France or Belgium—invariably feels, however friendly the people may be, that he is in a foreign land. Here it is entirely different. Though this is my first visit to America, I at once sank into American conditions as into a comfortable armchair, and after a little over 3 weeks I feel as much at home in New York as I do in London. The language no doubt largely explains it; that in itself is a great and vital bond. But the likeness extends to our sympathies, our moral outlook and our general point of view. It is a great comfort to feel that the foundation principles of the founders of the American republic are still the basis of national thought and policy, and while that remains I feel that America cannot go far wrong. The future of the world rests with the English-speaking race, and if America beats England in its efforts for the welfare and progress of mankind we shall applaud and never envy your success.

Economically, both countries seem to be running on almost parallel lines. Taking the chemical industry as an example, the armistice was followed by an unprecedented boom, during which money was made with astonishing facility. One result was to bring into the chemical industry large numbers of people who knew nothing about chemicals. They bought up chemicals as they bought up anything that came along because the scarcity was such that the speculator could sell anything he possessed at almost any price he cared to ask. That unhealthy condition disorganized trade, produced a false sense of prosperity and encouraged wild speculation. This stage ended with dramatic suddenness. In a moment trade came to a stop; the speculator was left with heavy stocks on hand, and the genuine trader found that instead of being able to sell anything he could sell nothing. The "slump" lasted about 18 months. It was the most severe in the history of British chemical industry. The large firms had to hold expensive organizations together. Many of them lost heavily, and I know of several instances where people had to sell their war bonds to pay income and other taxes. Now, fortunately, the depression has passed the lowest point, and a steady revival is in progress. That, in brief, is the history of chemical industry in England since the close of the war, and I gather that it is very much the history of it in America. Let us hope that for both there is a long period of prosperity ahead which will compensate for the losses and anxieties of the past.

Similarity of Conditions Is General

But the similarity between English and American conditions appears to be general. The finest address I have heard in America was one by Mr. Barnes, the president of the United States Chamber of Commerce, reviewing generally the present condition of American industry. Passage after passage might have been taken bodily out of that address and if put into the mouth of our Chancellor of the Exchequer or President of the Board of Trade they would have described exactly the condition of things in England. The primary need of settling down to work as the only real remedy, the damage caused to industry by strikes and the continual fear of strikes, the unwillingness of employers to embark on new enterprises until conditions have become reasonably stable, the irritation caused by meddlesome government restrictions, and the demand of the trader for freedom to get on with his business—these were the things that Mr. Barnes emphasized, and they are exactly the things which British economists and business men like my chief, Sir Ernest Benn, have been continually emphasizing at home.

Incidentally I have been impressed with the thoughtful and rseponsible tone of the American public men I have met. If one judged of America solely from the jumpy headlines splashed all over the pages of the daily press, one might assume the American to be a particularly blatant and noisy person, having, like the seed which fell by the wayside, no depth of earth. The truth is the very opposite. Most of the speeches I have heard have been distinguished by moral earnestness and sincerity, by great analytical and penetrative thought, by a desire to go quietly to the root of the matter, and by a sense of exactitude in the use of words excelling even our own standards.

Important Role of the Technical Press

This brings me to the question of the business and technical press of America. I came over to America as a delegate from the trade and technical press of London to the business press of America. I brought with me messages of greeting from a number of distinguished

journalists and public men, and nothing was more significant than their unanimity in emphasizing the important part the business press of both countries must play in getting national business once more on to sound lines. Politics here seems to be even more of a game than with us. It is a game of personalities and parties, and the daily press is largely a reflection of these conditions. The result is that business is often the sport of politics, and economic problems are handled not on sound economic principles, but with a view to catching the popular vote. There is a growing feeling with us that the genuine commercial community does not bring its proper weight to bear on national policy, and if it is to do so it must be largely through the medium of the commercial and technical press. The great journals, for example, of the McGraw-Hill Co. understand the conditions of the various industries they serve in a way the daily journal cannot pretend to do. They can ascertain and explain the bearing of legislative changes, like the substitution of a tariff for the dye embargo, with direct authority derived from first-hand acquaintance with industrial conditions. They are in a position to serve industry in a twofold sense—first, by acting as the spokesmen of commercial interests, and second, by informing legislators and public officials on questions about which they must otherwise remain ill-instructed. The commercial and technical press of America is a magnificent instrument for the service of American industry. It has already attained an influence and reputation extremely creditable to itself, and I am impressed by the extent to which it is used, both technically and commercially, by the great industries it serves. It has, however, not reached the limits yet. My impression is that it has a still larger mission, not only in educating the industries themselves and spurring them on to the very best commercial and technological methods but equally in educating the government in relation to industry and seeing that public legislation and regulations are based on a sound knowledge of industrial conditions.

Finds Americans Interested in British Affairs

One word more. It is pleasant to find how keen over here is the interest in British politics and trade. That does not support the theory that America has no interest in Europe. On the contrary, everywhere I go the inquiry has been, What is the future of Lloyd George? What is the present position of English political parties? What are England's economic and industrial problems and how is she going to face them? In spite of themselves Americans are interested in England and in Europe. Morally they cannot afford to live to themselves, even if that were commercially possible. America, as a land built on the principles of liberty and equal justice for all, has a moral duty to civilization which it cannot ignore without damage to its own moral fiber. I have formed the impression that the real wealth of America lies, not in its gold, but in its deep human sentiment and in its sense of the moral side of life. It is in these fundamentals that the essential unity of the English-speaking peoples come out. We in England speak but little perhaps of Anglo-American unity because with us it is so natural and inevitable that it does not need to be put into words. But it is good sometimes to give expression to what is in the hearts of both peoples, and I believe that the interchange of visits and ideas is equally good for both nations, and is good for the whole world. I shall carry back with me lasting memories of American hospitality and kindness, and the impression that, underneath our external divergences, there is a unity of mind and soul that must never be severed.

Chloride Volatilization

Notices of work done by the Bureau of Mines on chloridizing volatilization of complex ores have appeared from time to time in these columns. The process consists, in general, of calcining a mixture of ore and calcium chloride in a rotary kiln, whereupon metallic chlorides fume away, being recovered by a Cottrell treater. Values are then extracted from the fume (with recovery of the chlorine) by a simple melting with a limestone flux.

For several years the chemistry of the process has been under investigation at the Berkeley station. The vapor pressure of lead chloride and of silver chloride has been measured. In connection with the formation of silver chloride vapors in the furnace atmosphere it was necessary to study the hydrolytic dissociation of silver chloride and the necessary concentration of hydrochloric acid and chlorine to prevent this dissociation. Similar work is contemplated for the chlorides of zinc and copper as well as for sodium chloride. With a knowledge of the vapor pressures of the various chlorides it will be possible to gain an idea of the ease of formation of such chlorides in a furnace, and a study of the hydrolysis of these chlorides will give data as to the necessary furnace atmosphere in order to chloridize compounds of the metals involved.

During the original investigations at Salt Lake City, an excessive loss of copper and chlorine was noted when smelting the recovered fume, especially from copper ores. Experiments are now under way at the Seattle station of the Bureau of Mines, looking toward the design and construction of an electrical furnace for this duty, expecting it will not cause the losses which occur in fuel-fired furnaces. Experiments have also shown that the latter will not fume excessively if operated at less than 1,150 deg. C. and the fume introduced below the slag line.

Many valuable data on the commercial aspects of the process have been collected by observation of the operation of a volatilization plant at the Yellow Pine Mining Co.'s property, at Goodsprings, Nev. Some experiments were carried on at a plant in Harbor City, Calif., and a high-grade zinc oxide was manufactured direct from zinc carbonate ores. The volatilization tests on ores carrying less than one-half of 1 per cent lead gave complete volatilization of the lead. The results of the tests indicate that volatilization would free the zinc ores of sufficient lead content to make a commercial zinc oxide usable for all purposes other than for making automobile tires. (Zinc oxide for making automobile tires must contain less than one-half of 1 per cent lead.) The experiments proved satisfactory, a company is now being organized to construct a larger and more up-to-date plant to commercialize the process.

A great many experiments have been conducted on different low-grade and complete ores from Utah and other states. Practically complete extractions of lead and copper have been obtained, and the extraction of silver has been from 50 to 90 per cent. Most of the experiments were confined to complex and carbonate ores. It has been found that copper ore carrying its principal value in the form of chrysocolla is very difficult to volatilize.

European Conditions as I Saw Them*

Industrial Status of Belgium and Extent to Which She Is Suffering From German Competition—Comparative Transportation and Food Costs in Belgium and Germany Show the Abnormality of Conditions in Germany—Belgian Market for American Products

By J. S. Negru

IN RELATING impressions gathered through a series of interviews with industrial leaders, economists, labor leaders and the common people, it is not to be expected that one shall speak as authoritatively as if in possession of written proof of his statements. This is particularly true when, as is frequently the case, the opinions of those interviewed are diametrically opposed to one another. Similarly, visits to plants when limited to a few hours per plant seldom furnish material on which to base unquestionable statements. Such visits usually develop into mere sightseeing tours that may be interesting to those who have never seen similar plants before, but which, as a rule, become boresome to engineers familiar with more modern installations.

Factors Considered Before Reaching Conclusions

During my trip through Belgium I tried to follow a course with respect to interviews and plant visits that would give me a happy medium of results. Thus in my interviews I gave due consideration to everyone's point of view and opinion, but seasoned it later with my own personal deductions. When visiting Belgian plants I kept in mind the very important fact that, whereas in America labor-saving devices are a *sine qua non*, similar plants in Belgium would not be so equipped, due largely to labor conditions. In America, for example, there is a larger floating untrained class of workmen, whereas in Belgium it is possible to employ steadily a group of men with long years of training in their particular lines of work. Another factor considered in reaching my conclusions was that mass production is not yet, and never may be, as pre-eminent in Belgian industry as it is in American industry.

Status of Belgium Before and Shortly After the War

With these considerations in mind, the reader will get a clearer idea of the impressions I carried away after my trip through Belgium. This is a country with a population of nearly 8,000,000, on an area of about 11,800 square miles. The principal and practically the only valuable natural resources are a very industrious population and coal that can be mined only at the rate of 22,000,000 tons per year. From this it will be clear that the country has always had to depend on export business for its daily existence, and apparently always must so depend.

When the war came on and Belgium was invaded, the coal-mining industry alone was continued under pre-war conditions. All of the other industries suffered in a greater or less degree due to the lack of raw material and a lack of facilities for export. Another factor that seriously affected the Belgian industries was the policy of the invading army of forcibly employing a number of Belgians in war work for the enemy. When peace came, Belgian machinery of production was partly destroyed and the remainder badly disorganized. The people were still in a kind of stupor after a bad dream of over 4 years' duration. The immediate result was a transitory stagnation due to the difficulty of arriving at some practical readjustment. Then began the struggle accompanying the ever-increasing cost of needed raw materials, rapidly increasing wages, reduced hours of work, and particularly a very depressing and discouraging slowness in the resumption of their export business when confronted with German competition.

Present Status of Belgium

No doubt it would have been possible for me to collect such statistics as were available, and write with the documents at hand regarding production, imports, exports, wages, index numbers and the like. What I tried to get instead was the views of employers and employees, and some typical examples of the difficulties under which Belgian industry in general was laboring. By so doing I was in a position to draw conclusions as to the causes leading to the then existing situation in Belgium.

With few exceptions Belgian plants are working with machinery similar to that of pre-war times, but the status of employees has undergone quite radical changes. I learned from Mr. B., a Belgian labor leader, that the stand taken by him and his followers is something like this: "During 1920 and part of 1921 the employers grew fat; now it is the employees' turn." This summarizes clearly, I think, the existing friction between employers and employees.

The relatively high wages, averaging, say, $2, as compared with 60 cents in Germany[1], and a stringent application of the 8-hour law have made the fight for the resumption of exports almost an impossible task. The principal exceptions are for those commodities which it was a physical impossibility for Germany to supply due to the fact that she was crowded with previous orders.[2]

Extent to Which Belgium Is Suffering From German Competition

The great extent to which Belgium is suffering from German competition is well illustrated by the following incident. When I was in Aachen, Rhineland, a few miles from the Belgian boundary, early in April, I witnessed the very striking sight of hundreds of Belgian men and women carrying heavy baskets and bundles of newly bought cheap German products, which, I learned, they would sell the same evening to merchants in Belgium. In this manner a thriving business is carried on every day on a small scale with made-in-Germany pipes, cigarette holders, knives, watches, jewelry, pocketbooks,

*This is the third of a series of articles by Mr. Negru on this subject. The first appeared in the Oct. 18 issue, the second in the Oct. 25 issue.

[1] When comparing money values I will use the average exchange prevailing at the time. In round figures $1 equals 12 Belgian francs, equal to 300 German marks.

[2] In confirmation of these observations made during the latter part of March, I may cite the following paragraph from the *Bergwerk Zeitung* of Essen published in the New York *Times* for Sept. 10, 1922: "It is characteristic of the situation that a large concern was not in a position to deliver in time to the factory the sheet iron required for the manufacture of trams for its own mines, although these trams were urgently required. The requirements of the mines for trams has greatly increased. The factories in question are fully occupied until February."

stationery and the like, all being commodities that require large amounts of hand labor. Belgian customs men were very lenient with this class of "importers." Similar traffic on a trainload scale is the rule.

Discrepancy Between Buying and Selling Prices

In order to give an idea of the great discrepancy between the buying and selling prices of commodities thus imported into Belgium, I will cite a few examples from my personal experience. A pipe bought in Germany for 40 marks sold in Belgium for 8 francs, respectively about 13 and 70 cents; a cigarette holder of material looking like Bakelite which sold in Brussels at 1.75 francs could be bought for 8.50 marks at the Tietz department stores in Berlin, respectively about 15 and 2.8 cents; an umbrella bought in Aachen for 380 marks was for sale in Belgium at 40 francs, respectively about $1.30 and $3.30; a pocketbook which in a Berlin store cost 125 marks was for sale at the Brussels Grand Bazaar for 22 francs, respectively 40 cents and $1.85. These comparisons could be continued indefinitely for practically all of the supplies constituting the great bulk of wares sold in the Belgian bazaars and department stores.

With machinery and apparatus it is quite the same. Both Mr. P. and Mr. S., contracting engineers, answered my question as to where they obtained their electrical and other supplies with the very suggestive, "En Bochie" (in Germany).

Is it then to be wondered at that Belgian domestic industry suffers so very severely from German competition?

Neither the German workingman nor the German manufacturer profits from this superdumping policy. On the other hand, a few middlemen and merchants are rapidly growing rich at the expense of German labor to the detriment of the Belgian workingman and merchant.

The extent to which Belgium relies on German-made goods is well illustrated by a short news item published in *La Gazette* of Brussels, April 14, 1922. It has its amusing side, but it is very suggestive of the practical difficulties confronting Belgium in the recovery of her industrial life. I give a translation:

> Last Sunday a flag was presented at Mons to the Amicale des Sous-Officiers Anciens Combattants [Society of Veteran Non-Commissioned Officers]. On the occasion of this patriotic demonstration illustrated postal cards were sold for the benefit of the war invalids.
>
> We have on hand one of these postal cards. It represents the Arcade of the Cinquantenaire.[3] Under the French text one can read: "Brussel, Die Arkade des 50 jährigen Jubiläums."
>
> On the address side there is a brief description of the arcade, but in German only.
>
> Germans furnishing illustrated postal cards for Belgian patriotic demonstrations! You recognize them there.

Comparative Transportation Costs in Belgium and Germany

The cost of railroad and street car transportation in Belgium deserves attention in comparison with similar costs in Germany.

The shortage of coal is far more acute in Germany than it ever was in Belgium, yet the cost of transportation by railroad and street car is, respectively, about one-fifth and one-third what it is in Belgium. Thus the fares from Hamburg to Cologne and from Cologr to Brussels for similar comforts were, respectivel $2.60 and $5.30, although the distance as the cro flies between each two points is about as 2 is to 1. Th uniform street car fare in Germany was 3 marks, sa 1 cent, while in Brussels the fare varies with the di tance, the minimum in the so-called second-class con partments being 0.25 franc, or over 2 cents.

Is this not a clear indication of the reason for suc great deficits in the operation of German transport tion systems, even when taking into consideration th very low average wages of German employees, about 5 cents per day as compared to about $1.70 in Belgium

Comparative Food Costs in Belgium and Germany

In like manner it might be interesting to give a insight into the difference in the cost of food in th two countries.

It would be confusing to take restaurant prices, a they vary with the class of restaurant. I will consider therefore, the prices in the dining cars of railroads o the respective countries, as these are officially fixed fo table d'hôte meals. The cost is about two and a hal times higher in Belgium, although the German meal i perhaps the more generous of the two. As to the cos of food in homes, I learned from conversations wit ordinary citizens of the laboring class that it is abou four times higher in Belgium than in Germany.

From my own experience I know that in pre-wa times the average living costs in Germany and Belgiur were in proportion of 1 mark (25 cents) to 1 fran (20 cents). The present conditions become more strik ing when it is realized that Germany must import eve more now than before the war.

Does it not follow logically from these figures that th cheap living for Germans in Germany on their minimum for-existence wages is utterly abnormal, especially whe we consider that the intrinsic value of German product is now even somewhat higher than it was befor the war?

Research in Germany

To some it may seem beside the mark that I shoul dwell on these matters when I might have been lookin for information regarding research and technical proc esses in Germany, but in my judgment these facts an figures show that people living under such condition have little, if any, opportunity for scientific researc and for changes that are not absolutely necessary.

I can assure my readers that research and experi ments on how to make ends meet with the presen wages are conspicuously and steadily carried out b the wives of scientists in these countries.

Fallacy of Statistics on American Imports From Belgium

During a conversation with Louis Strauss, repre sentative in the Belgian Chamber of Deputies, Alder man and for many years in charge of the harbor o Antwerp, I brought up the subject of Belgian export to America. I explained that our Monthly Summar of Foreign Commerce of the United States gave, unde the heading "Imports from Belgium," figures whic appeared to be quite important, whereas it was m impression from what I had seen and learned that the represented business far beyond what Belgium reall was doing. Mr. Strauss then explained to me that th figures given in these reports represents merely th

[3] The arch in Brussels commemorating the fiftieth anniversary of the independence of Belgium.

products reaching America via Antwerp without due consideration of their original source, and that the greater part of the products classified as Belgian is in reality foreign. Most of them come from Germany and are merely shipped through Belgium. This fact has to be kept in mind when studying such figures.

Policy of Selling Below Cost

When I was in Düsseldorf I learned from Mr. H. some facts that gave me the impression that certain Belgian metallurgical plants are selling for export at prices below cost. When I was again in Belgium a few days later I succeeded in getting some very reliable data that fully corroborated my first impressions.

It will suffice to mention the case of the Providence Company of Charleroi, which underbid the Germans for 5,000 tons of rails for Bulgaria. The bid was 368.5 francs per ton c.i.f. Bourgas, Bulgaria, which represents 314 francs per ton at the plant. At the same time the quoted price in Belgium was between 400 and 425 francs per ton. The explanation given to me was that the Belgian metallurgical industry was forced into this emergency policy in order to avoid shutting down the plants.

In order to learn how the Belgian metallurgical workers looked upon this policy of selling below cost, I interviewed Mr. Baeck, general secretary of the Syndicate of the Belgian Metallurgical Workers. From my conversation I gathered the impression that the workmen give practically no thought to the economic conditions that force their employers to adopt a policy of selling below cost. He summarized the situation by saying briefly, "Ca, c'est leur affaire" (it's their business).

I left Belgium under the impression that industry there is recuperating quite rapidly. This is due not so much to the recent reduction in wages, which are now about $1.70 per day of 8 hours, but to the inability of the Germans to continue much longer their abnormally low cost of production and their superdumping selling price. These conditions make Belgian products accessible in foreign markets and will tend to stimulate local industry. Fortunately, the Belgian experience of selling for export at prices below cost was short lived.

Belgian Market for American Products

Practically all those with whom I spoke regarding opportunities in Belgium for the sale of American products stated that there is a big field for American labor-saving machinery and apparatus and other products, but that present prices are beyond their reach.

With reference to the cost of American products in Belgium, I had a few experiences that led me to the conclusion that one reason why American products are beyond the reach of the average Belgian is plain profiteering by Belgian merchants. As an illustration I may cite the case of a well-known pencil which sells in America for $1 but which was selling in Brussels and other Belgian cities at a fixed price of 25 francs, then about $2.15. From a conversation with Mr. N. of the Musée Commercial in Brussels I learned that the tariff cannot be held responsible for this discrepancy in prices, nor can the cost of transportation be held to blame. In the store where I bought one of these pencils it was explained to me that the price was fixed in the American office, but that does not seem well founded.

I am under the impression that Belgian representatives of American firms are charging for American-made goods as much as the traffic will stand. This may appeal to some as good business, but in reality it keeps the market opportunities within very narrow limits and creates the wrong impression that good American products cannot be had at reasonable prices even in a country with depreciated money such as Belgium.

This and other similar incidents were the subject of an interview with the European representative of a large American electrical manufacturing company, from whom I learned that many American firms are quite satisfied to be represented in Europe solely by natives, and give very little thought to the need of exercising some kind of supervision over the policies adopted by these representatives.

There is a great market in Belgium for American products, especially now when they seem to appreciate the advantages of American industrial equipment. Other favorable conditions already mentioned are the slow but sure elimination of abnormal competition from Germany and the gradual recuperation of domestic industry.

A plan that I think might appeal to American manufacturers is to sell modern industrial equipment to Belgium on a basis that will permit payment to be made from increased production efficiency. I know that such a plan would appeal very favorably to the Belgian industrials, who are already beginning to feel the need of modernizing their plants.

Other articles on this subject by Mr. Negru will be published in subsequent issues.

Candelilla Wax in Mexico

Since the close of the world war production of candelilla wax has shown little life, says a report from Consul F. R. Robinson, at Saltillo, Coahuila. Recently reports have been current of a revival of interest in this line, and it is understood that European interests have gone so far as to make inquiries with the object of contracting for the local output. In former years practically the entire output went to Germany, and Europe has continued to be the best market for this commodity. In 1917 a considerable amount was shipped to the United States, and was found to be very satisfactory. The cost of the local product has advanced about 25 per cent over pre-war prices, labor and other incidental costs having increased.

From 2 to 5 years, dependent upon the amount of rainfall, is required for the production of the candelilla weed, from which the wax is obtained. Primitive methods are still employed in Mexico, the present yield of wax being only about 2 per cent of the weed employed, but it is expected that improved methods will soon be perfected whereby 3 per cent of pure wax together with about 2 per cent of valuable resins will be obtained.

Limestone Quarry Studies

The United States Bureau of Mines has recently undertaken a study of limestone quarrying for lime manufacture, in connection with which a series of short papers on various phases of the industry will be issued. The purpose of these reports is to discuss conditions, methods and equipment, in order to permit higher efficiency and safety in the operation of the quarries. The first of these papers, Serial 2401, "Stripping Problems in Limestone Quarries of the Shenandoah Valley," by Oliver Bowles, is now available and may be obtained from the Bureau of Mines, Washington, D. C.

Atlantic City Meeting of the American Gas Association

Record Attendance and Exceptional Exhibit Combined With Numerous Papers and Committee Reports Make an Exceptional Convention—Papers on Carbonization, Coke Production and Cooling and Condensing of Gas of Greatest Engineering Interest

EDITORIAL STAFF REPORT

ANY convention which has 2,500 members and guests registered cannot help being enthusiastic. And when this large attendance is supplemented by a well-planned exhibit of wide interest to the industry and a fine program of technical papers and committee reports, there is no excuse for any one failing to have a profitable time. It is safe to assume, therefore, that with all these advantages the American Gas Association meeting at Atlantic City, Oct. 23 to 27, establishes a record for the industry.

OFFICERS AND MEETING FOR 1923

For the coming year the work of the association will be guided by the newly elected president, R. B. Brown, general manager of the Milwaukee Gas Light Co., and J. B. Klumpp, of the U. G. I. Co., Philadelphia, the newly elected vice-president. H. N. Brundage, of New York City, was re-elected treasurer, the only other elective office filled by action at this session.

For the 1923 meeting the committee reported in favor of Chicago, if adequate facilities can be arranged, or, failing that, for Atlantic City as an alternate place. There is considerable sentiment in favor of another meeting at this latter city, for the Steel Pier affords to the industry excellent facilities for exhibit of all types of manufacturing and gas-burning equipment that are of interest, as well as adequate space for convention meetings. The 1923 meeting will probably be held early in October, as there is strong sentiment, as indicated by the committee report, in favor of slightly earlier time of meeting than this year.

The Technical Section of the association for the coming year will be under the chairmanship of F. C. Weber, of the Henry L. Doherty Co., and the vice-chairmanship of H. C. Wehnert, of St. Louis. It is in this branch of the association that practically all the engineering and chemical work is done.

EXHIBIT FEATURES

The active interest of all branches of the industry was greatly stimulated by the splendid exhibit of gas-making, gas-distribution and gas-utilization equipment. Evidence of engineering in gas utilization was clearly shown; and the gas appliance men are evidently coming to appreciate that they must give as much attention to appliance appearance and to refinement of detail as has been characteristic of electric appliances in the past.

It is notable that at least three types of automatic control equipment for water-gas operation were on display. Several types of coke ovens were also exhibited by models in a most effective way. Other plant equipment was also shown by several dozen exhibitors.

Gas-metering devices of new types were especially conspicuous. The automatic continuous recording calorimeter of the Cutler-Hammer Co. was shown as a companion instrument to the well-known Thomas meter for measuring gas volumes. These two were accompanied by a third "B.t.u. meter" which was an indicating and continuous recording device for showing the total B.t.u. in the gas. This device is really an indicating, recording watt-hour meter producing a record of the product of B.t.u. per foot (normally measured by a continuous recording voltmeter), and the cubic feet per hour (ordinarily shown by an ammeter).

Another meter that aroused much interest among the engineers present was of the positive displacement type using the same general form of construction as the Root-type exhauster. This device, made with frictionless bearings and somewhat greater precision in other respects than the usual exhauster, was exhibited by the Connersville Blower Co. The meter on exhibit, though taking only a few square feet of floor space, was capable of handling 60,000 cu.ft. of gas per hour. As set up there it was operated by the breeze from a small desk fan directed against the inlet of the meter, showing that with 0.1 in. of water pressure the meter could be started and operated without difficulty. At maximum capacity only 0.5 in. of water pressure is required as a differential between the inlet and outlet. This device is suggested not only for station metering but also for use on industrial consumers' premises. It promises on further development to be of considerable interest in many other industries, for a meter of this simple type would probably lend itself very well to many chemical engineering problems where the metering of gas flow is one of considerable difficulty.

PRESIDENT'S AND TREASURER'S REPORTS

D. D. Barnum, of Boston, the retiring president, emphasized in his address the magnitude of the technical problems of the industry, but pointed out that these increased problems really represented increased opportunity for the industry. Adequate supply of raw material, a decreased unit charge for gas-making investment and low cost generation of the gas were problems of special importance emphasized in this address. The commercial necessity of handling much larger volumes of gas in order to meet heating loads and give good service were also stressed, as well as the usual problems of the relationship between management and employee and between the company and the public.

The report of the treasurer was received with great enthusiasm, for it showed the finances of the association to be in splendid shape and outlined extensive operations in the past and the coming year which are covered by a budget of approximately $250,000 per year. The assets of the association in securities, cash on hand and other property now exceed $100,000.

GAS DISTRIBUTION PROBLEMS

A further presentation of the "Doherty Ideal Distribution System" was made by R. G. Griswold, of the H. L. Doherty Co. He discussed in this paper the basic

principles which underlie selection of piping systems for gas distribution involving the minimum investment and the minimum annual total cost per unit of conductivity furnished. The scheme of judging proper distribution pipe size by the minimum cost per unit of conductivity per year was emphasized. Henry L. Doherty personally contributed a written discussion to this report, bringing out further the ideas upon which this system was originally based when proposed and tried out on a small scale in a number of cities some years ago. The principles discussed would be equally applicable to selection of pipe-line sizes for any other types of gas and hence they afford rather wider interest than is customary for papers dealing with city gas distribution.

Standard Pipe and Meter Sizes

Standard specifications for cast-iron pipe and specials were adopted in revised form by this convention. Full engineering details regarding these pipe sizes are given in the printed committee report already available.

The meter committee of the association took a definite stand in favor of changing meter size nomenclature. Under the new scheme proposed the case and pipe-connection sizes would be indicated by the first part of a meter size number and would correspond to the meter numbering now in vogue under the system of designation by "lights." The committee, however, proposes to add the rating in cubic feet of gas passed per hour through the meter with a standard loss in pressure between inlet and outlet. This rating would form the second part of the meter size number. Thus a meter designated as "30-600" would be one having case and pipe connections the same as an old style 30-light meter and a gas capacity of 600 cu.ft. per hour with a loss of one-half each water pressure between inlet and outlet.

Deposits in Gas Pipes and Meters

A committee on deposits in gas pipes and meters under the chairmanship of R. L. Brown, of the Bureau of Mines, reported on research done in the laboratory of the chairman of the committee. The investigation thus far shows that a number of the organic compounds such as styrene and indene, which polymerize and oxidize readily, are probably the usual gum-forming constituents of the gas. The cause of the very great increase in trouble due to gum in meters and pipes was suggested by the tentative conclusions announced. The high oxygen content in manufactured gas today, particularly carbureted water gas, is believed to be a prime factor in gum formation. The presence of excessive condensable vapor in the gas, of course, would be serious and the high rate of oil input practiced today in many water-gas plants probably gives rise to incomplete cracking of the oil and consequent production of gum-forming bodies. The committee recommends as practical preventives for the trouble (1) reducing the oxygen content of the gas to a minimum, (2) as complete condensation of gum-forming constituents in plant and holder as possible, and (3) so far as practicable prevention of the formation of these gum-making constituents by more efficient oil cracking in the carburetor of the water-gas set. The most feasible method of getting this better oil cracking is to reduce the rate of oil input into the carburetor.

Condensing and Scrubbing of Gas

Two very important articles on cooling (or "condensing," as the gas man calls it) and scrubbing of gas were presented. In an article on "The Use of the Doherty Washer-Cooler as a Water-Gas Condenser," by F. W. Steere, of Detroit, gave a very excellent report on the principles underlying washer-cooler equipment design. The principles brought out in Mr. Steere's paper are applicable in a wide variety of gas-handling equipment.

Scrubbing and condensing facilities for a coal-gas plant were discussed by J. H. Wohrley, a member of the committee on gas plant and production. Some of the more important points brought out by Mr. Wohrley's discussion are as follows:

"A desire to obtain the maximum capacity and efficiency at the smallest investment, and at the same time utilize a minimum amount of valuable space, has led to the investigation of the possibility of designing a form of apparatus which would provide for combining the condensing scrubbing, extraction of tar and removal of ammonia in a single shell or a series of shells.

"The complete scrubbing of the gas is a matter of vital importance, as it is necessary to admit a clean gas to the purification system, even though it may require that a small percentage of vapors be sacrificed to do so. The ultimate results attained will in general be more satisfactory when viewed from the financial standpoint.

"In considering the general lay-out of a system which is believed will provide for the proper cleaning of the gas, removal of the byproducts and incidentally the removal of a portion of the impurities, a diagram is given.

"The apparatus consists of a primary scrubber located ahead of the exhauster. The cooling of the gas from the foul main temperature to approximately 70 deg. F. is brought about in this scrubber.

"A curve shows the amount of heat that theoretically must be removed per 1,000 cu.ft. of crude coal gas in cooling through various ranges of temperature. From this the theoretical amount of liquor can be calculated. The degree to which the actual and theoretical amounts will agree will depend largely upon how intimately the gas is brought into contact with the saturated liquor.

"The following table shows the amount of liquor necessary and the sq.ft. of cooling coil required per 1,000 cu.ft. of gas passed for various inlet temperatures where the gas is to be cooled to 70 deg. F.:

Inlet Temp., Deg. F.	Gal. Per Min.	Sq.Ft. Coil Area
120	0.26	6.6
125	.29	7.9
130	.31	9.3
135	.34	11.1
140	.37	12.8
145	.38	14.4
150	.45	17.9
155	.51	21.6
160	.59	26.3

"The ultimate temperature to which the gas may be reduced upon leaving the primary scrubber will, of course, be limited by the temperature of the cooling water used on the cooling coils, and upon the surrounding atmospheric conditions. However, with cooling water of approximately 60 deg. F., there will be no difficulty in bringing the temperature down to 70 deg. F. This differential of 10 deg. F. should represent a maximum when proper adjustments of liquor flow and cooling water flow have been made and when due consideration has been given to the area of the cooling coil surface, the distribution of the scrubbing liquor and the design of the filling used in the shell."

Sketches show the difference in action in an ordinary

tubular condenser and that taking place in a tray-filled shell. The difficulties and advantages with the direct contact system as compared with the indirect system of cooling are fully treated in the complete paper. The different types of scrubber fillings and methods for making sprays for wetting the grids or other filling are also discussed. Results of operating tests are presented to bring out the practical results which can be expected from different kinds of equipment.

As a result of the investigation the author concludes that the washer-cooler installation permits minimum cost of maintenance and operation, has a minimum space requirement, requires no buildings except for pumping equipment, has simplest construction with no moving parts, has maximum cooling efficiency and is capable of reducing the temperature to a point most favorable for complete removal of ammonia. The results achieved with such apparatus provide for delivering only clean gas to the purifiers and for the maximum recovery of both tar and ammonia, the two important byproducts involved.

The report by Mr. Wohrley also discusses the various kinds of loss and methods of computing and controlling loss of ammonia during recovery from coal gas. The principles involved in this discussion would, of course, be equally applicable to coke-oven systems.

Accident Prevention

The committee on accident prevention had rather a full report discussing resuscitation, first-aid equipment, gas masks for plant and distribution department use, and the methods of organizing safety work. Of widest technical interest is the detailed report which forms one of the appendixes of the committee report, dealing with resuscitation from carbon monoxide asphyxiation. This report is based on an extended experimental study of treating carbon monoxide poisoning by means of oxygen plus carbon dioxide. The work was done by Dr. Yandel Henderson and Dr. H. W. Haggard, assisted by a number of collaborators and assistants.

These investigators conclude that manual artificial resuscitation by the prone pressure method should be employed whenever respiration has ceased, but that using oxygen plus carbon dioxide simultaneously aids greatly. The breathing of oxygen plus 5 per cent carbon dioxide causes very complete ventilation of the lungs and greatly accelerates elimination of carbon monoxide from the blood. There is nothing difficult about this administration and it requires no more careful supervision than any case of asphyxiation. The authors believe that this rapid elimination of carbon monoxide greatly decreases the likelihood of nervous disorders or pneumonia following carbon monoxide asphyxiation.

A separate report on masks for gas plants recommends the hose type of mask with air blower for all-around use and warns against promiscuous use of army masks and advises against depending upon the oxygen-type mask for simple work or the cannister-type unless adequate oxygen supply is known to exist. The first-aid equipment and methods of safety organization recommended are suited to general industrial plant purposes.

Carbonization Committee Report

The carbonization committee of the association presented one of the most complete and valuable reports ever given to the gas industry by any association committee. The work, as in former years, was divided in several parts, typical operating results being considered by one sub-committee, low-temperature carbonization by a second, complete gasification by a third and new types of construction by a fourth.

The committee announced that further work would be done during the coming year with an appropriation of $3,000 which has been granted for experimental research at Ohio State University, using the vertical retort installation already there and a new horizontal retort which is to be installed. The present equipment represents a single full size U.G.I. vertical. The horizontal retort to be installed is being contributed by the Improved Equipment Co., representing typical small-plant construction of a modern sort.

Typical operating results were not reported by the committee this year, because it felt that the basis of reporting had not been adequately studied formerly. The committee, therefore, gave a great deal of time to the revision of the forms on which coal carbonization results should be recorded and reported. These revised forms are given in full and are now proposed for comment and criticism, before adoption for use during the coming year by the new committee.

Operating results were reported by the committee from the plant at Racine, Wis., where "outside producers" are used. This work is similar to that presented at the 1922 convention of the Wisconsin Gas Association.

Firing Coke Ovens With Blue Gas or Producer Gas

W. R. Morris, assistant superintendent of the Seaboard Byproduct Coke Co., gave a full report on an experience at that plant using blue gas and producer gas for firing coke ovens. The results with the two fuel gases were strictly comparable, because the work had been carried out simultaneously on almost identical batteries of ovens and had extended over considerable periods of time. Full operating data are given from which the author draws the following very important conclusions:

(*a*) The overall or the gasification and combustion efficiency of producer gas is much greater than that of blue gas as shown by the following comparison:

	Producer Gas	Blue Gas
Pounds dry fuel to carbonize a ton of coal	225	295
Pounds of carbon to carbonize a ton of coal	199	261

In other words, only 76.3 per cent as much fuel is required with producer gas as blue gas to carbonize coal.

(*b*) Poorer and less salable grades of coke can be more readily used in a producer plant.

(*c*) Producer operation requires much less labor per ton of fuel gasified.

Since the collection of the operating data given above, we have put through our six producers for a period of 3 weeks almost 300 tons of coke per day, or from 45 to 50 tons per producer per day without any appreciable difficulty and no addition of labor.

Carbonizing 50 tons per day per producer and 50 tons per day per blue gas generator the labor is:

Producer 0.51 man-hours per ton gasified;
Blue gas 1.50 man-hours per ton gasified.

In the entire producer plant there is required no labor whatever of the particularly heavy or arduous type, while no one questions the strenuous task of clinkering a water-gas generator.

(*d*) Continuity of operation of a producer plant is such that the machines run for weeks and months at a time with no attention other than watching that the conditions set are regularly maintained. The possible mechanical derangements are a minimum. This must appeal particularly to the water-gas man, familiar as he is with the intermittent operation required with a water-gas generator.

(*e*) Mixing the blue gas and producer gas with coal gas for the purpose of obtaining a specified B.t.u. can be done with equal ease.

(*f*) The manufacturing cost of blue gas per million B.t.u. is fully 40 per cent greater than producer gas. This cost is based on the same value for generator fuel in each case, which is decidedly unfair to producer gas as it uses inferior and therefore cheaper grades of coke.

Conclusions—As a part of a large byproduct plant furnishing gas for city use a blue-gas plant has advantages over a producer plant in times of coal shortages, caused by strikes or other contingencies beyond the control of the manufacturer. Also in a business depression, when the market for coke is poor and prices low, a blue-gas plant is desirable because more blue gas than producer gas can be mixed with the coal gas, which also means that a greater percentage of coke can be turned into gas.

However, for anything like a steady operation a producer plant is a far better proposition:

First, because of its greater efficiency in changing heat units in the form of carbon to a combustible gas.

Second, because of the simplicity and ease of operation.

Third, because of the far lower manufacturing cost.

Low-Temperature Carbonization

The sub-committee on this subject reported by means f three technical papers. The first, by J. D. Davis, of he Bureau of Mines, who was chairman of the sub-ommittee, discussed "Low-Temperature Tar and Its valuation." Two of the important conclusions reached y this author are as follows:

Low-temperature tar may vary considerably as regards yield and character of its constituents, depending on the conditions under which it has been generated. If, for example, it is desired to produce a tar in which the constituents have suffered the least alteration, it is necessary to carbonize at the lowest practicable temperatures and to remove the tar vapors quickly from the heated retort, either by evacuating or by circulating inert gases. This procedure reduces the gas yield to a minimum and results in the production of an inferior semi-coke. Tars generated at intermediate temperatures and distilled at atmospheric pressure undergo more or less thermal decomposition, with the result that the gas yield rises and a coke dense enough for domestic use is produced.

In the United States it may pay to develop a low-temperature carbonization industry primarily for the production of a domestic fuel with motor spirit as a liquid byproduct. Certainly such an industry would effect a conservation of our fuel resources and tend toward abatement of the smoke nuisance caused by the domestic consumption of soft coal. It would not greatly affect present established carbonization industries. Another possibility is complete gasification of bituminous coal with preliminary carbonization at low temperatures, the tar to be worked up primarily for motor spirit. In any case, the main tar product will probably be motor spirit, and low-temperature tars should be evaluated with this idea in view.

Internal and External Heating of Retorts

The second paper presented by this sub-committee as by Charles V. McIntyre, of New York City, who iscussed "Internally Heated Retorts." Problems and rocesses for internal heating with producer gas, water as, coal gas, superheated steam and products of combustion were all presented. The author gives the impression that the most encouraging of these processes re those which contemplate the use of water gas as the iedium of heat transfer. Of course, such method eally results in a complete gasification process or some ear approach to that result.

Internal heating of retorts must be done at extremely w temperature to prevent the coal from becoming lastic or the retort must be equipped with mechanical irring devices. As a result internal heating of re-rts results in producing a char instead of a coke. his material is granular and dusty and suitable, in eneral, only for grinding into powdered fuel for stok-s or for briquetting or for use in producer-gas or water-gas making. The author concludes that "the most successful internally heated processes operate in conjunction with, and deliver their entire residue to, gas producers or water-gas generators.

External heating of retorts for low-temperature carbonization was discussed by Dr. Harry A. Curtis, of the Clinchfield Carbocoal Corporation, who gave special attention to the problem of transferring heat to the coal mass through the retort body. As a very complete discussion of this general subject has been prepared by Dr. Curtis for publication in *Chem. & Met.* at an early date, no further discussion is required here.

Complete Gasification of Coal

The sub-committee discussing complete gasification reported through its chairman, R. G. Porter, of Chester, Pa., regarding a number of the fundamental problems of city gas supply using very lean gases. Emphasis was laid upon service problems involved with such gas and the possibilities of house heating and other extension of gas service for replacement of solid fuel. As appendixes to the report there are given descriptions of a number of the successful processes for complete gasification that have been used for short periods in a few localities. These descriptions include the Tully gas plant, the J. U. McDonald process as applied at Valparaiso, Ind., and the Doherty complete gasification plant at Toledo, Ohio.

New Gas-Plant Construction

The builder's section of the committee furnished a number of brief reports on new types of gas plant construction and new plant machinery. This group of reports included a description of the Roberts oven, by H. V. Patterson; a description of charging and discharging machines of the Bartlett-Heyward type, by H. L. Underhill; carbonization apparatus of the Gas Machinery Co., by W. E. Steinwedell; continuous type Glover-West vertical retorts, by E. G. Blackwell; new type Koppers oven, by H. J. Rose; the new carbonization plant built by the Russell Engineering Co. at Lowell, Mass., by Vernon Baker; the new Semet-Solvay byproduct coke and gas ovens, by C. R. Bellamy; and further details on the U. G. I. Contracting Co. installations of vertical retorts, by J. H. Taussig. Mr. Taussig is chairman of this sectional committee.

Preparation and Merchandising of Coke

W. G. Rich discussed the commercial problems in merchandising coke, giving as illustrations of the methods discussed a full report on the domestic sale of coke in Providence, R. I. Special emphasis was laid on the problems of advertising the product effectively.

"The Manufacture and Preparation of Coke" was the title of an article by R. L. Fletcher, who is also connected with the Providence Gas Co. Although written from the standpoint of a gas man, the author laid great emphasis on the necessity of treating coke as a principal product, instead of merely a byproduct of gas. The preparation of coke to form a satisfactory substitute for coal, of equal or greater efficiency for general use, was shown to be an entirely feasible matter.

Mixing of coal and pulverizing the mixture were urged to produce good water-gas coke as well as high-grade domestic fuel. The methods and equipment for handling the coal for charging and the proper methods for screening and crushing of coke were described. It is especially notable that the equipment recommended

by this author for gas-works is almost exactly that commonly employed in the byproduct coke-oven plants. Problems of storage, sizing, sampling and analysis were also discussed briefly.

Availability of Papers

The Gas Association had preprinted the principal papers and committee reports, hence those specially interested can procure most of the material of greatest value by application to the association headquarters, 342 Madison Ave., New York City.

Balls Used for Hardness Testing

J. J. Curran, of the Henry Souther Engineering Co., speaking before the Detroit meeting of the American Society for Steel Treating, described some tests made on four different kinds of balls intended for use in Brinell machines. One lot of plain carbon steel was made by a foreign manufacturer, another of chromium-tungsten steel was made by the Hoover Ball-Bearing Co., and the two others were chromium steels of local manufacture.

Surface polish—an essential for durability in a ball bearing—seemed to have little to do with their utility for Brinell testing. The best balls (as it developed) had a very inferior polish. All of the balls of all varieties were measured and passed a rigid inspection for shape.

When testing by a scleroscope, mounted in a special fixture, the balls of carbon steel seemed to be hardest. When mounted three above each other and crushed, the results were so erratic that conclusions could not be drawn. Finally, two disks of Cr-W steel (ball steel) were hardened carefully, a ball placed between them, and 3,000 kg. load applied. This test was repeated on three balls of each variety, the disks being indented in a different place each time. Invariably the two indentations made simultaneously by a single ball were identical, so it appeared that the disks were of uniform and equal hardness. However, the carbon steel ball gave the smallest impression—i.e., indicated the highest hardness in the disk (approximately 700). Other varieties of balls indicated valves as low as 600. Lastly, each ball was remeasured for permanent deformation. Each one was flattened by the single test it had performed, but the flattening was least in the hardest ball (carbon steel).

From these results it seems desirable to get the hardest ball possible for use in a Brinell machine.

Evaporation Losses of Petroleum Products

In the general study of evaporation losses of crude oil and refined products, being made by the Bureau of Mines, an elaborate series of tests has been made at a Ponca City, Okla., plant to determine the relative rates of evaporation of gasoline when stored in ordinary tanks and tanks fitted with water-sealed roofs. Tests were also made to determine the amount of gasoline that was lost in filling a tank car with straight-run gasoline of 56 to 58 deg. Bé. gravity. Temperature measurements are being made to determine the temperature of oil in three different types of tank—one of the ordinary 55,000-bbl. type, one an 80,000-bbl. insulated tank, and one a 55,000-bbl. insulated tank on which a water spray is used. Arrangements have been made for conducting a series of tests to determine evaporation losses at an Okmulgee, Okla., refinery.

A Practical Method for Preventing Explosions Due to Accumulations of Static Electricity

By Hilton Ira Jones
Director of Research, The Redpath Bureau

In JANUARY, 1919, we were working on the preservation and sterilization of eggs.[1] In the course of this work we employed an R.U.V. ultraviolet light outfit, and also produced enormous pressures according to the system of Hite (University of West Virginia) followed by sudden vacuums. This was accomplished by placing the eggs in an equal molecular mixture of oxygen and hydrogen gas, exploding the mixture and condensing the water vapor. In the course of this work we observed a marked change in the discharge of the Ruhmkorff coil whenever the ultraviolet machine was operating near it. Also we employed a Cenco Hyvac pump and on several occasions got the ordinary spark discharges from the belt when the machine was running, and we observed that these immediately disappeared as soon as the ultraviolet outfit was started. We have also for several years performed as a regular demonstration in general chemistry the explosion of powdered starch in an inclosed chamber. We used a sewer tile set in a cement base and covered with strong paper, tightly tied. A small amount of finely divided starch was blown in a small hole at the base. The mixture was exploded both by placing a flame at the hole and also by a spark discharge between two points within the tile. On this particular day we prepared the demonstration in the room where an X-ray was running and we were disappointed at our inability to make the explosion take place with the spark as usual.

Investigations on Cause and Prevention

During the past year we have been carrying out experiments in connection with the work of the dry cleaners, mainly in the revivification of the waste gasoline by a new process, soon to appear. An explosion of the gasoline vapor in the "tumbler" of one of the plants in the city led us to investigate the cause and possible prevention.

Our experiments and observations have led us to see that most "mill dust" explosions, gasoline "tumbler" explosions and indeed a majority of powder mill explosions are caused by sparks of static electricity. These may be prevented, at least in nearly all cases, by ionizing the air. This has the effect of causing the static to "drain off" quietly and harmlessly as fast as produced. In fact it is quite impossible to produce static or other electric spark explosions in the presence of highly ionized air.

The air may be thus protectively ionized in many different ways, by ultraviolet light, by X-ray, by radioactive substances or any other means that will cause the emission of electrons in sufficient concentration. A tube of the type of the old Crookes tube we have found best. Some glasses are much more permeable to the electrons than others. We are now taking up with the Corning Glass Co. the production of a special glass for the manufacture of a tube for the ionization of the air in factories and mills. We are hoping that these may be placed on the market soon. Appropriate patents are of course being applied for.

Chicago, Ill.

Accounting Needs of Technical Men in Executive Positions

Accounting Needs Technical Balance as Much as the Technical Executive Needs Accounting—Pertinent Examples Are Discussed—Finally the Type of Accounting Knowledge Needed by the Executive and the Means of Obtaining It Are Outlined

By F. W. Thornton, C.P.A.
Price, Waterhouse & Co.

From articles that have already appeared in this publication, it seems that there still are executives in the chemical and metallurgical industries who believe cost accounting to be without value, at least for them. This belief is probably held by technical men with small accounting knowledge who now occupy executive positions. On the other hand, there are in all lines of industry executives who are not technical men but who have a good knowledge of accounting and who think they can prove from cost accounts many things that are not so. Both classes of executives are half wrong and half right, due to the fact that they are only half equipped for their positions.

Perhaps in no other business is the need for technical knowledge to direct cost accounting so great as in the chemical and metallurgical industries.

Executive heads if not originally technical men cannot be expected, after they have become immersed in business, to acquire a sufficiently exhaustive knowledge of the technical side of a chemical or metallurgical industry to serve them as they should be served. Executives can and generally do obtain some knowledge of the technical side of their business, but the ideal executive is one who, originally a technical man, has obtained a good knowledge of accounting and gone forward into the executive department. Nothing produces more unsatisfactory results than a strict separation of the lines of promotion of technical and non-technical men similar to the division between the line and the staff in the Army.

An Example of the Need of Technical Guidance

The history of LeBlanc soda offers one of the best examples of the need for technical guidance in cost accounting. Originally soda (soda ash or carbonate) was the only product aimed at. Hydrochloric acid was a byproduct of little value, often a waste product; salt cake was not then used in glass manufacture, so-called "sulphate" paper was not manufactured, and except as horse medicine there was little if any sale for sodium sulphate. At that time correct cost accounting would have taken as the cost of the soda ash the entire cost of manufacture less whatever was recovered for HCl or other byproducts.

Then the ammonia process came, producing better and cheaper soda; it produced no HCl; and this latter product rose in price. Eventually the LeBlanc process was continued only because of the HCl—or bleaching powder—which it produced. At this time correct cost accounting would have shown as the cost of bleaching powder the entire cost of manufacture less whatever was received for soda, which became a byproduct, or for recovered sulphur.

Finally electrolytic soda and chlorine have come; the LeBlanc process is almost dead except that the first step—the manufacture of sodium sulphate—continues, the salt cake being sold as such.

Clearly the only present reason for continuing is the production of sodium sulphate, the HCl being a byproduct. Correct cost accounting will show as the cost of the sodium sulphate the entire cost of manufacture less whatever is received for HCl or other byproducts.

"Process," Not "Product," Should Be the Cost Basis

It will be noted that a great error into which non-technical cost accountants fall is the endeavor to show separate costs for each *product*, whereas a better basis is the cost of each *process*. In the issue of Aug. 16 there is pointed out (page 296) an absurd result that could be arrived at by the application of doctrinaire cost accounting—namely, a profit on Na_2SO_4 with a concurrent loss on HCl, and as a result the suggestion that the business be pushed in salt cake but not in HCl. We can go much further with process costs. The product is Na_2SO_4 plus HCl, and assuming for illustration that the salable forms were (Na_2SO_4, $6H_2O$) and aqueous acid containing 19 per cent HCl, the output of each will be, approximately, in the ratio of 1 lb. salt cake to 1½ lb. hydrochloric acid. The cost account should show as the unit of cost 1 lb. salt cake plus 1½ lb. hydrochloric acid, whereupon the possible selling price of the sodium sulphate could readily be computed by deducting from the unit cost the current market value of 1½ lb. hydrochloric acid, then adding profit expected. Much mental discomfort awaits the cost accountant who attempts to show separate costs for joint products.

What Is a "Process" for Cost Accounting Purposes?

But if the process were to be continued further, the HCl converted into hydrochlorite and salt cake into soda ash, what should be done?

In speaking above of the "process" as the basis of a cost account, it is considered that for this purpose a "process" is complete when a freely marketable commodity is arrived at. The object of every cost account should be to show whether the manufacturer is making (1) a profit, (2) how much profit, (3) the greatest possible profit.

In the case under consideration, we have arrived at a point where we have two readily salable products with current market prices easily ascertainable; then if the products are to be used as the raw material for bleaching powder and soda ash, the first process of manufacture should be credited with the salt cake and HCl at the current market prices; for if the succeeding processes cannot make a profit on this basis, it would pay better to sell the salt cake and HCl as such; a transfer at any other price would hide the truth. If, for instance, the salt cake were transferred to the next

process at cost, the manufacture of soda ash might show a profit, which might be correct. But it would not show whether the greatest possible profit had been obtained. If it had been charged with sodium sulphate at the price that could be got in open market and had then made a profit, it would be evident that the conversion had paid.

Some cost accountants would say this was "not fair to the HCl." Not fair! Then have chemicals rights not only independent of but contrary to the interests of their owners?

During all this time a person with an excellent knowledge of cost accounting but no knowledge of chemistry would have produced cost accounts that could only be called silly, and a chemist without any knowledge of cost accounting would have done no better.

Technical Judgment Essential in Considering Obsolescence and Depreciation

It is to be noted that there are spoken of above only those periods when changes of trade conditions had arrived at a definite stage; there were, in between, periods when the ammonia process was making slow headway and when the electrolytic process was not an assured success. It is precisely during such periods of changing conditions that there is most need for the technical man to direct the cost accountant, having in view probable early obsolescence of plant.

The questions of depreciation and obsolescence also call for much technical knowledge. The bookish cost accountant often holds that the "only correct" method is, say, the setting aside of a percentage of cost—or of diminishing value—or a rate per unit of product, etc. This is mere foolishness. Again it may be repeated that cost accounting is useful only to show what profits are or can be made. Some assets have a life that can be computed within reasonable limits and give substantially 100 per cent service during that life—a steam boiler, for example. Others may have a relatively indefinite life, subject to frequent repair or with a gradually increasing inefficiency.

Freight steamships have a life, generally speaking, of about 20 years; they are usually depreciated at 5 per cent of cost each year; they become somewhat more troublesome and inefficient as they age. At first sight it would seem that the rate for the first years is too low, but here a factor enters that is too often ignored—namely, the interest on the capital absorbed. Thus, for a ship costing $1,000,000 the real carrying and depreciation cost for the first year is 5 per cent on investment plus 5 per cent depreciation—in all $100,000. At the end of 10 years the cost is 5 per cent on investment (now reduced to $500,000) plus 5 per cent depreciation —in all $75,000. It is because of this drop in interest on investment that plants long in use, with the average of all items half worn out, are valued usually at more than half the replacement cost. The interest on investment does not and should not appear in the books.

Where a plant gives increasingly inefficient service as it becomes older, the need for high depreciation rates during the period of high efficiency becomes greater; if 100 per cent service is given during the entire life of plant, the distribution of its cost equally over its whole life rather favors the later periods when the invested value has become reduced. Common sense must decide, not arbitrary rules.

Precisely similar conditions are presented in chemical and metallurgical industries. A simple knowledge of how long a tank furnace making glass will live, without a knowledge of its increasing demand for roof repair as it grows older, will not enable a cost accountant to depreciate it properly; and who but a technical man could say how much more rapidly it would wear out if a change were made to use a new sand containing, say, 2 per cent more Al_2O_3, with perhaps 100 deg. increase of temperature?

Flexibility of Cost System With Changes in Process

Suppose that at this moment the ammonia soda process should be so changed that at small extra expense the HCl were obtained free. What would be the cost of that HCl? Surely not the amount of the additional manufacturing cost, for such a change would certainly bring about a drop in the price of soda. Then the cost of the HCl would be the additional expense plus the loss on the price of soda. Who could separate the amount of that loss? Cost accounts dealing with the process, not with each product, solve the difficulty.

The distribution of joint costs, burden and other expenses is simplified by the substitution of process costs for costs of each product. There are also cases where a group of joint products may partly be varied at the will of the chemist; a byproduct might be either ethyl alcohol or acetic acid, as he chose. A knowledge of what can be produced and the relative cost of production for alternative products, and the selling prices, all enter into the problem of the best selection of processes. The chemist must be an accountant or the accountant a chemist to meet such situations.

All this is now recognized to such an extent that the student who is preparing for a career as chemist or metallurgist usually takes some accounting course, and we may leave the colleges to deal with him. But no reasonably adequate provision has been made for the men who have gone far in technical work and are in line for executive positions but are without the accounting knowledge that an executive must have, nor for technical men who are so responsible for profitable operation that they must, to some extent at least, supervise and check the cost accounting of their departments.

To suggest that they go back to school and take a regular course in accounting may be a counsel of perfection—it is impractical. Such men already have developed an intelligence that should make it needless to go through the drudgery of learning bookkeeping, etc., in the ordinary way; it is not necessary for an executive to know all the details of bookkeeping. They should, indeed, understand the general principles of books—the old simple theory of ledger, cashbook and journal—and should understand cost accounts. They *must* be able to read and understand operating statements, profit and loss accounts, and balance sheets, and must be able to interpret them so as to get from them all the information they can give as to the progress of the business.

Where changes of process, raw materials or machinery occur, it is easy enough to find whether, and how much, a department has increased its profit; but in addition to the specific change there are constant other changes that affect profits, such as variations in water and coal supply, hours of labor, disposition of employees —and the executive head should be able so to dissect and analyze operating statements as to determine the effect of any given factor.

The course of study for technical men of experience should, therefore, be individual and not class study. The instruction of a really able accountant, if possible one with some technical knowledge or a public accountant

ith experience in chemical or metallurgical work, ould be obtained. An elementary knowledge of simple ookkeeping is assumed—almost every educated man as it. Then the course of study may well be similar) that outlined below.

First the student should take up "process" cost ac-ounting. This is the simplest and most satisfactory orm of cost accounts. "Job" costing may well be mitted, as it is not of much use in either chemical or etallurgical work, is far more difficult to master and less satisfactory under the best conditions.

"Process" costing is that species of cost accounting hat deals with the continuous manufacture of a product -such, for instance, as the manufacture of glycerine, f beer, or raw photographic film, of pig iron. "Job" osting deals with the production either of single large nits, such as locomotives, ships, pianos or with the anufacture in batches of smaller articles, such as anicure sets (in lots of, say, 10,000) watches, scientific nstruments, machines.

Generally, chemicals, metals, alloys, glass and all bulk roducts are covered by process costing, while elaborat-ng processes resulting in finished articles are usually overed by "job" costing. Continuous production of mall articles in great numbers may be the subject of rocess costing. Single lots of special chemicals may e the subject of job costing.

It will not be necessary for the student to take all is examples of process costing from his own business; here is such a family resemblance between process osts of all trades that benefit will be had if costs of ther trades are studied. It will even tend to enlarge he student's knowledge of the resources of process osting methods beyond what could be got from con-ideration of the accounts of his own industry.

Operating Reports, Profit and Loss Accounts and Balance Sheets

Then, to fit the technical man for the highest execu-ive positions, he should make a study of a series of perating reports, profit and loss accounts, and balance heets, all preferably of the enterprise with which he s connected and if possible bearing notes of changes n methods, processes, etc., with dates of introduction f the changes. First he should compare the successive eports, trace the results of changes, trace the results hown in daily or weekly operating statements to the rofit and loss accounts, and trace the effect on the alance sheet of the profits and losses shown. All this hould first be done alone. Then the teacher should go ver the same matter, the student noting the conclusions rawn by the teacher and, most particularly, the eacher's reasoning on which those conclusions are ased. The student need not accept either the reason-ng or the conclusions; that is immaterial, as the object f the study is to acquire the working tools of ac-ounting.

Suppose you have certain plant that has become obso-ete; it can be used to produce a certain article, but is otherwise valueless. Assume further that the article an be produced and sold at a profit provided that noth-ng is charged for depreciation of the plant. Many doctrinaire cost accountants insist that full depreciation be charged to cost, showing a net loss less in amount than the depreciation charged. Such cost ac-ounts, showing a loss in operation, would lead to the abandonment of the work, although the owners would be better off to continue it while the old plant lasted, using all profit in the amortization of the old plant. The remaining loss on the plant should be taken up separately. Much contention is avoided by making up cost accounts showing, first, cost before depreciation and obsolescence, then the provision for these purposes, and finally cost including depreciation and obsolescence. You can even add to cost an amount representing interest on capital, although that is by no means recommended. As Mark Twain has it, "First get your facts and then you can distort them as much as you please."

No Special Literature Needed for Chemical Accounting

The literature of cost accounting is not lacking in correctness, volume or variety, the problems of the chemical and metallurgical industries are those of other industries with such modifications as local conditions may indicate. A competent technical man with an accounting education that had not been in any way directed to the special work of his industry would have no difficulty whatever in adapting his accounting knowledge to his needs. There is an accounting variation between individual enterprises within these industries far greater than the variation between the industries as a whole and other lines of business. One company makes a thousand and fifty-seven varieties of chemicals and drugs, from sirup of squills to kakodyl cyanide, and has thousands of small customers, while another confines itself to the production of acid phosphate manure and sells its entire product to one other company. No special literature for chemical or metallurgical accounting seems to be needed.

In studying profit and loss accounts and balance sheets, particular attention should be given to the burden of excessive inventories, of idle capital caused by plant not in use, of excessive deterioration of plant due to corrosive materials handled, and the loss of operating time due to repairs. All these considerations are of a character that cannot be fully understood and correctly dealt with either by the accountant alone or the chemist alone. After making a study of such reports and accounts as are available from the enterprise in which the technical man is engaged, there should be obtained similar series of balance sheets and profit and loss accounts from other businesses, preferably businesses where the history of changes is known to the teacher and the accounts have been published so that they are no longer private in character; these should be worked over as outlined above.

A course of this kind will be found deeply interesting and will give the intelligent technical man a working knowledge of accounts in far less time than such a knowledge could be acquired in any other way. It will cover exactly the ground that in an executive capacity he may be called upon to cover.

Finally, to the advanced technical man some advice may be given that could scarcely be given safely to a young student; do not permit yourself to imbibe from any teacher the idea that any form of cost or other accounts is the only correct one, or that any statement or cost account that brings out clearly the facts is in contravention of the "true principles of accounting." As the greatest accountant of them all has said, There is but one true principle of accounting and that is to make accounts up in such a way as to show with the greatest clearness possible all the facts. Let your teacher have his way, but in your own mind remember that you are arming yourself with the tools of accounting and afterward will do with them whatever you think right.

Tests on High-Tin Bearing Metals

High-Speed Gas Engines Require Bearings of Highest Quality—General Remarks on Chemical Composition and Microstructure of Suitable Alloys — Detailed Directions for Casting in Bronze Shells—A Series of Commercial Alloys Were Tested for Hardness, Compressive Strength, and Coefficient of Friction — Bearings Were Also Run Dry Until Destroyed

By P. W. Priestley

ANTI-FRICTION bearing metals do not appear to have received the attention of investigators which they deserve. In view of the large quantities employed in the automotive industry alone, it is surprising to find that very little information is available which is of direct value to the engineer in the selection of white metal bearing alloys. Recently a number of investigations have been made by eminent workers and the data now on record form an admirable help in proceeding to examine the mechanical properties of these alloys.

It appears urgently necessary to establish a commercial form of test (applied particularly to durability and wearing properties). The test might directly indicate a definite unit property, or alternatively a formula showing relative merits between commercial mechanical tests. Service records would prove of extreme value to those concerned in the design, construction and application of machinery incorporating anti-friction bearing metals.

The following remarks apply mainly to a number of high-grade proprietary bearing metals of British origin, tin-base mixtures which have been successfully applied in high-speed internal combustion engine construction. It is hoped that serviceable information will also be found by those engaged in wider fields.

Microscopical

It is considered that the essential characteristic of a desirable alloy is to have hard grains imbedded in a relatively soft material. The function of the hard material is to resist wear and to provide a surface having a low coefficient of friction. The softer constituent permits a uniform distribution of load due to the possibility of adjustment, partly by distortion and partly by rapid wear, leaving the particles of the hard constituent in slight relief. It is further claimed that the hollowness of the softer areas assists in promoting lubrication. It is, therefore, necessary to obtain an alloy too hard to permit lateral flow and yet soft enough to adjust itself under load. Microscopical examination of a typical tin-antimony-copper alloy reveals cuboids of antimony-tin and long needle-like crystals of copper-tin forming a series of long bearing points imbedded in a matrix or cushion formed by the tin ground mass.

Chemical

Satisfactory results are obtained with the binary alloys of copper-tin, tin-antimony and lead-antimony, but the ternary alloys tin-antimony-copper, tin-lead-copper and tin-antimony-lead are better. Unfortunately the ternary alloys have not been thoroughly investigated, but it may be stated that the tin-antimony-copper mixtures are at the present stage most successful in the motor car under actual working conditions. There is little difference in the coefficient of friction of the tin-base alloys and the lead-base alloys; it is the ground mass which characterizes the two types. The lead-rich alloy is considerably weaker in compression and tension at normal working temperatures than the tin-rich allo and it is now generally accepted that the service to b obtained is controlled by the strength of the groun mass.

Antimony increases hardness, wearing qualities an brittleness. High casting temperatures cause heav antimony losses.

Bismuth may be introduced to the extent of a trac in the capacity of a flux.

Copper is comparatively readily soluble in tin, an prevents segregation and increases hardness. Whe present in quantities exceeding approximately 5 pe cent, copper promotes brittleness and a tendency t crack when used in high-speed engines. Casting tem perature is increased by increasing amounts of coppe with a consequent coarsening of the structure. I alloys containing this element, rapid cooling consider ably increases the hardness as compared with slowl cooled alloys.

Iron increases hardness and brittleness, and is con sidered an undesirable impurity.

Lead in small proportions is permissible, since it presence increases fluidity during casting. In th solidified metal lead promotes ductility and resistanc to rapid changes of loading. American practice per mits quantities up to 0.35 per cent, and it is present i the ground mass of the alloy, having little effect upo the melting point. English practice generally exclude this element in quantities exceeding 1 per cent. Larg quantities produce a soft alloy and cheaper product and it is possible that lubricants containing an exces of alkali will pit lead-rich mixtures. One of the alloy selected for this investigation contained approximatel 20 per cent lead. The tests showed that while th metal exhibits the smallest dimensional change unde compressive load (greatest Brinell hardness), it wil withstand only a comparatively moderate load withou cracking. This fact must materially affect lateral flow and at the same time prevent adjustment of the groun mass.

Nickel in quantities not exceeding 0.50 per cent in creases ductility and removes the liability to crack with out affecting the wearing qualities. In the tests t be presently described it is seen that a high-tin allo having 0.53 per cent Ni withstood the highest com pressive load without sign of cracking, but that thi property was accompanied by the greatest dimensiona change under load (smallest Brinell hardness) of an of the metals selected for examination.

Tin in large percentages promotes rigidity and in creases wearing qualities. The cost of a bearing meta is controlled by its tin content, since this element i by far the most expensive ingredient contained in an form of anti-friction bearing alloy.

Zinc creates a tendency to seize and increases hard ness and brittleness. It is possible that a detrimenta action may take place in the presence of salt water o benzol when zinc is present. This element is considere

a undesirable impurity. It is interesting to note that periments have been made in France and England ith zinc base bearing metals. An alloy which has met certain amount of favor is one containing 70 per cent nc and 30 per cent tin. A binary series of alloys zinc and tin will not contain the relatively hard nstituents necessary, and a ternary alloy having a ser resemblance to the tin-antimony-copper mixtures der consideration is developed by the introduction of nall quantities of antimony and copper. A mixture hich has been utilized for relatively heavy duty con- ins 80 per cent zinc, 15 per cent tin and 5 per cent pper. A bearing metal of French origin introduced ith the object of reducing to a minimum the use of e more expensive metals has a composition 63.3 per nt zinc, 21.3 per cent tin, 12 per cent lead and 3.3 r cent copper. In the absence of data relating to ese comparatively complicated mixtures the ternary loys maintain their established position in Great ritain.

Casting Practice

The initial preparation of the alloys, alloying proce- re and handling during pouring influence the struc- re considerably and in turn the service attainment any bearing mixture.

When a warm sand mold is employed, slight differ- ces of temperature do not materially affect the struc- re of the tin-antimony-copper mixtures except that e arrangement of copper-tin needles is more regular an when a cold sand mold is employed.[1]

Cold metal molds or molds warmed to a temperature proximately 100 deg. C. produce a metal with chilled rders, and a rise in pouring temperature from say 0 to 400 deg. C. increases the depth of the chill. hen the temperature of the mold is raised to 200 deg. and a casting temperature of 350 deg. C. is employed, e structure is uniform and fine grained throughout, coming somewhat finer at the extreme edges. Brinell sts[1] indicate that chill-cast specimens are generally rder than sand-cast examples.

In sand castings there is a marked diminution in e number of relatively large crystals at the bottom of e casting ingot and a corresponding increase the top, showing that the crystals have a lower ecific gravity than the liquid tin-rich matrix in which ey are found, and a tendency to rise to the top is ted when slow solidification is permitted.

The structure of these alloys should not be excessively ne or coarse, and the best results are obtained when ured at a temperature slightly over the freezing int. A casting or pouring temperature of 300 deg. C. not likely to produce a uniform structure, since this mperature is just below the liquidus of the alloy and e liquid already contains crystals of one of the nstituents.

On the other hand, a casting temperature of 600 deg. produces a coarse crystalline structure with large ntimony-tin cuboids. A casting temperature of 400 g. C. produces cuboids of smaller dimension, but the pper-tin constituent does not form the network char- teristic of slow cooling when warm sand molds are mployed. In chill castings there is considerably less ifference between castings poured at 300 and 400 deg. respectively than in sand castings. A fine granular ructure is seen in both cases, but it is more uniform hen poured at the higher temperature.

[1] "Observations on a Typical Bearing Metal," by Fry and Rosenhain; British Institute of Metals, 1919, vol. 2.

The antimony-tin cuboid crystals in chill-cast alloys are uniformly distributed throughout the entire section, whereas a concentration of these crystals is found at the top of sand castings. During solidification there is a tendency with certain mixtures for the antimony-tin cuboids to rise to the top of the metal, and the only method of prevention lies in chilling the molten metal to bring about rapid solidification.

A distinct softening is noticeable at a temperature of 100 deg. C. and it is thought that the hardening effect of rapid cooling indicates that the rate of cooling rather than the casting temperature controls the ultimate hardness.

Under scleroscope test a chilled alloy has a hardness practically double that of the slowly cooled metal (12 or 13 against 6 or 7), while the Brinell impressions are almost identical (28 and 25 respectively). Hence the hardness produced by rapid cooling is more apparent under comparatively light load than under a heavy load. It becomes necessary therefore to review carefully the duty which a bearing metal has to perform in considering the desirability of heat-treatment. Extremely slow cooling of the molten metal produces a dangerous crystalline structure which may lead to the development of cracks under service conditions in a similar manner to that which may obtain as the result of a high pouring temperature.

Service results depend very largely upon careful and skilled manipulation during pouring operations, and the procedure listed below is a very successful method of lining a bronze shell of the class employed in automotive construction. To prevent oxidation and loss of the antimony constituent it is essential that small quantities of metal only are melted. Where a large number of shells are manipulated, it is very desirable to have a number of small melting pots conveniently arranged with spouts and handles which are in turn immersed in a superheated bath of old metal for the purpose of melting the new metal. Extreme cleanliness and considerable attention to detail are necessary in the production of high-grade bearings.

To prepare the shell:

(1) Heat it in a bunsen flame to dull red.

(2) Immerse it in strong boiling solution of caustic soda for one minute.

(3) Tin carefully and completely over a bunsen flame with solder containing 30 per cent Pb and 70 per cent Sn, employing the following flux: anhydrous zinc chloride 50 per cent, ammonium chloride 49 per cent, and sodium fluoride 1 per cent.

(4) Wash in clean boiling water to remove flux.

(5) Mount in a fixture which should set the horns of bearing in the highest position and provide a suitable header.

Preparation of metal:

(1) Employ small melting pots conveniently arranged with spouts and handles.

(2) Carefully clean and coat pots with black lead prior to each pour.

(3) Do not melt more than 1 or 1½ lb. of metal in each pot.

(4) To melt metal immerse pots in a bath of old molten metal provided with suitable burners to maintain between 325 and 350 deg. C.

(5) Stir well and frequently.

(6) Graphite may be used as a flux to prevent oxidation.

Pouring:

(1) Preheat fixture and shell by immersion in bath of molten metal at 325 to 350 deg. C.

(2) Puddle cast with clean wire to insure that air or gas bubbles rise to header.

(3) Quench in water when metal solidifies.

Thermal Treatment

Heat-treatment is unnecessary in small bearing shells,

since no difficulty is experienced in cooling them with sufficient rapidity to obtain the desired structure. It is advisable to heat large bearings to a temperature of approximately 150 deg. C. and quench in water. This eliminates segregation of the antimony-rich cuboids.

Physical Properties

The resistance to tension of a bearing metal has no direct relation to its anti-friction qualities. Since no bearing alloy is ever expected to sustain tension strains, no information is available. Elongation and reduction of area are the only data resulting from a tensile test which could possibly be considered of value. It may be assumed that a large reduction of area indicates great ductility which under service would cause a bearing to spread or squeeze out under relatively small loads. Conversely, it may be expected that a comparatively high tensile strength, accompanied by little or no reduction of area or elongation, is best suited for bearing purposes.

The general rule that the brittleness of an alloy increases rapidly with hardness does not obtain in the tin-rich alloys, which, even with relatively high hardness values, show no signs of brittleness under impact stresses. The presence of nickel up to say 0.50 per cent considerably increases the ductility of tin-antimony-copper bearing metals. Cracks may develop as the result of a high casting temperature, particularly if the bearing be subjected to repeated shock or vibration.

It is thought by some authorities that the scleroscope hardness test excels the Brinell method on account of greater differences revealed after heat-treatment. The writer is strongly of the opinion that the scleroscope test has little value, since considerable variation in the readings must obtain on account of the essential characteristic of the alloy, which demands hard bearing points imbedded in a cushion or matrix of softer material. It is evident, in the absence of any definite relationship between hardness and wearing qualities, that any form of hardness test applied to this type of material has little merit in the consideration of endurance qualities.

However, there is a relationship between Brinell hardness and compressive strength in tin-rich alloys. It may be noted here that a mixture having a Brinell hardness 34 has an approximate compressive strength of 24,000 lb. per sq.in., and that with a decrease of hardness value there is a proportionate increase of strength under compressive load within a range terminated by an alloy having a Brinell hardness 20 accompanied by a compressive strength of about 42,000 lb. per sq.in. The compression figures indicate the load which the metal will withstand without cracking, and the limits of the range quoted represent the extreme conditions observed by the author. Chemical composition and rate of cooling considerably affect the hardness values and the ability of an alloy to withstand compression stresses.

Mechanical Tests

The writer recently examined very exhaustively nine high-grade proprietary tin-rich bearing metals with the object of determining their relative suitability for high-powered automobile engine construction. Table I shows their chemical composition.

Each alloy was poured at the respective temperature recommended by its maker, as shown in Table II, and all test-pieces and test-bearings were heated to th temperature named and quenched in water with th object of eliminating the segregation of antimony-ric cuboids.

Brinell hardness tests are noted in Table II, and r sults of compression on cylinders 1 in. diameter ar 1 in. long are given in Table III.

Coefficients of friction varied from 0.002 to 0.0(depending upon the temperature and bearing, as show in Table IV. In performing these tests, a bronze bea ing block was given a $\frac{1}{2}$-in. white metal lining.

A 6-in. journal was rotated, at 360 r.p.m. (565 ft. p min.) for several days, both in forward and rever direction, in order to obtain a perfectly smooth bearir surface. The surface of the bearing measured 4.8 sq.i and was loaded with 4.800 lb., or 1,000 lb. per sq.i Lubricant used was sperm oil. Tests were run for hours, with the journal rotating in either direction, ar average results are given in the table.

It was intended to test the resistance to wear, usir a standard bearing and journal, and under varyir conditions of load, oil pressure and temperature, ar journal speed. Preliminary trials with two of the bea

(*M*) Bearing melted.
(*a*) Bearing slightly fused but none adhered to journal.
(*b*) Bearing badly fused, and metal adhered to journal.
(*c*) Bearing badly fused but none adhered to journal.

ıg metals indicated that the wear exhibited after a onsiderable period was infinitesimal. Since little inormation of value was likely to be obtained from tests xtending over many months, it was decided to abandon his project and to proceed with durability tests (which orm the subject of Table V) in order to obtain comparative values with respect to the behavior of each alloy ı the unlubricated condition. The same bearing and ournal used to determine the coefficient of friction was sed. However, the load was reduced to 500 lb. per q.ft. On starting the test, the bearing was flushed ith sperm oil at 60 deg. F. for a period of 10 minutes, hen the bearing was drained. From then on the temerature and friction were observed at intervals of 5 inutes until the alloy fused.

The interpretation of the mechanical tests recorded ıust be governed by the particular application for hich the bearing alloy is required, and while the investigation indicates that the metals examined are without exception of a very high order, it should be noted that the order of merit has particular reference to their suitability for high-powered automobile engine bearings.

First place must be given to alloy 1, which can withstand exceptionally high compression load without cracking, has a moderate dimensional change under excessive load, an exceptionally low coefficient of friction, and will run longest when dry. Second place was assigned to alloy 8. It also stands great loads before cracking, has a moderate dimensional change under high load, has a low coefficient of friction, and will run over an hour dry without melting. Alloy 9 is a close third, attaining the desirable qualities to only a slightly lesser degree. Alloy 4 is ranked next, its rather quick failure when running dry being counterbalanced by an exceptionally low coefficient of friction.

The German Vegetable-Oil Crushing Industry

The present condition of the German vegetable-oil rushing industry with regard to the number of mills, ıe working force, amount of raw material treated, and ıe output, as compared with the last pre-war year, ras reported in *Commerce Reports* of Aug. 14, 1922, nd is shown in the following table:

	1913	April 1, 1921, to April 30, 1922
umber of mills	134	95
umber of workmen employed	6,700	10,000
mount of tons of oil fruit crushed	1,800,000	670,000
utput of oil in tons	650,000	265,000

The present capacity of all the German oil mills mounts to about 2,200,000 tons of oil fruits—i.e., more ıan three times the actual output. In 1913 Germany xported about 70,000 tons of oil. In 1921 the imports mounted to 163,000 tons.

The share of Greater Hamburg in the German oil industry compared with the provinces of Mecklenburg nd Schleswig-Holstein is about 55 per cent. Harburg, thriving industrial city near Hamburg, is an especially nportant oil center.

It is of interest to note the increase in the number of borers, the main reason for which is stated to be the ıtroduction of the 8-hour working day.

Dutch capital is strongly interested in German oil ills, and at present no legal discrimination exists gainst foreign capital.

Collapse of the Carbide and Cyanamide Industries at Odda

Recently the plant of the Alby Carbide Co. at Odda was sold at auction for 50,000 crowns to satisfy judgments amounting to 1,900,000 crowns, and the plant of the Northwestern Cyanamide Co., a subsidiary of the Alby Co., for 200,000 crowns, to satisfy debts aggregating more than 11,000,000 crowns. Both plants were bid in on behalf of the Tyssefaldene Power Co., which was the chief creditor of both concerns. This marks the final collapse of two of the largest industrial undertakings in western Norway and the practical bankruptcy of the community of Odda, which is now petitioning the state for a moratorium and for cancellation of taxes. These plants employed from 800 to 1,100 men.

The Alby Co. was a British corporation organized with a capital of £725,000 and registered in Norway in 1907. Between that time and 1918 the capital was increased to a total of 15,000,000 crowns. Its plant was built on ground leased from the Tyssefaldene Power Co., and at maximum operation had an annual output of about 90,000 tons of calcium carbide. The Northwestern Cyanamide Co. was organized with a capital of 2,000,000 crowns to utilize part of this output and for several years took from 50,000 to 60,000 tons annually of the product for conversion into cyanamide, a fertilizer material. The remainder of the product was exported.

Properties of Salt Solutions

By W. L. Badger
Professor of Chemical Engineering, University of Michigan

IT HAS BEEN the experience of the writer in connection with his consulting work in salt manufacture that it is often difficult to obtain usable data on the properties of sodium chloride solutions. Some of the data which have been found most useful in connection with problems of design and operation of equipment for salt refining have been collected and plotted on a comparatively large scale. These curves are reproduced in the accompanying charts in the hope that they might be of service to other workers in this field.

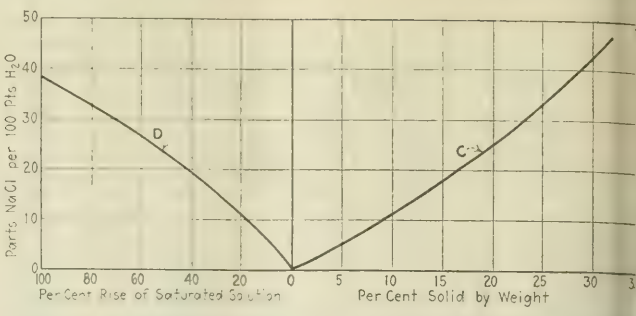

FIG. 2—COMPOSITION OF SALT SOLUTIONS; BOILING POINT OF UNSATURATED SOLUTIONS

How to Use the Curves

Boiling Point of Saturated Solutions. In Fig. 1 curves *A* and *A′* are for saturated salt, and curves *B* and *B′* for water. Enter the chart at the bottom with the temperature at which water boils under the pressure considered, go up to Curve *A*, and read the boiling point at the left. The vertical distance between *A* and

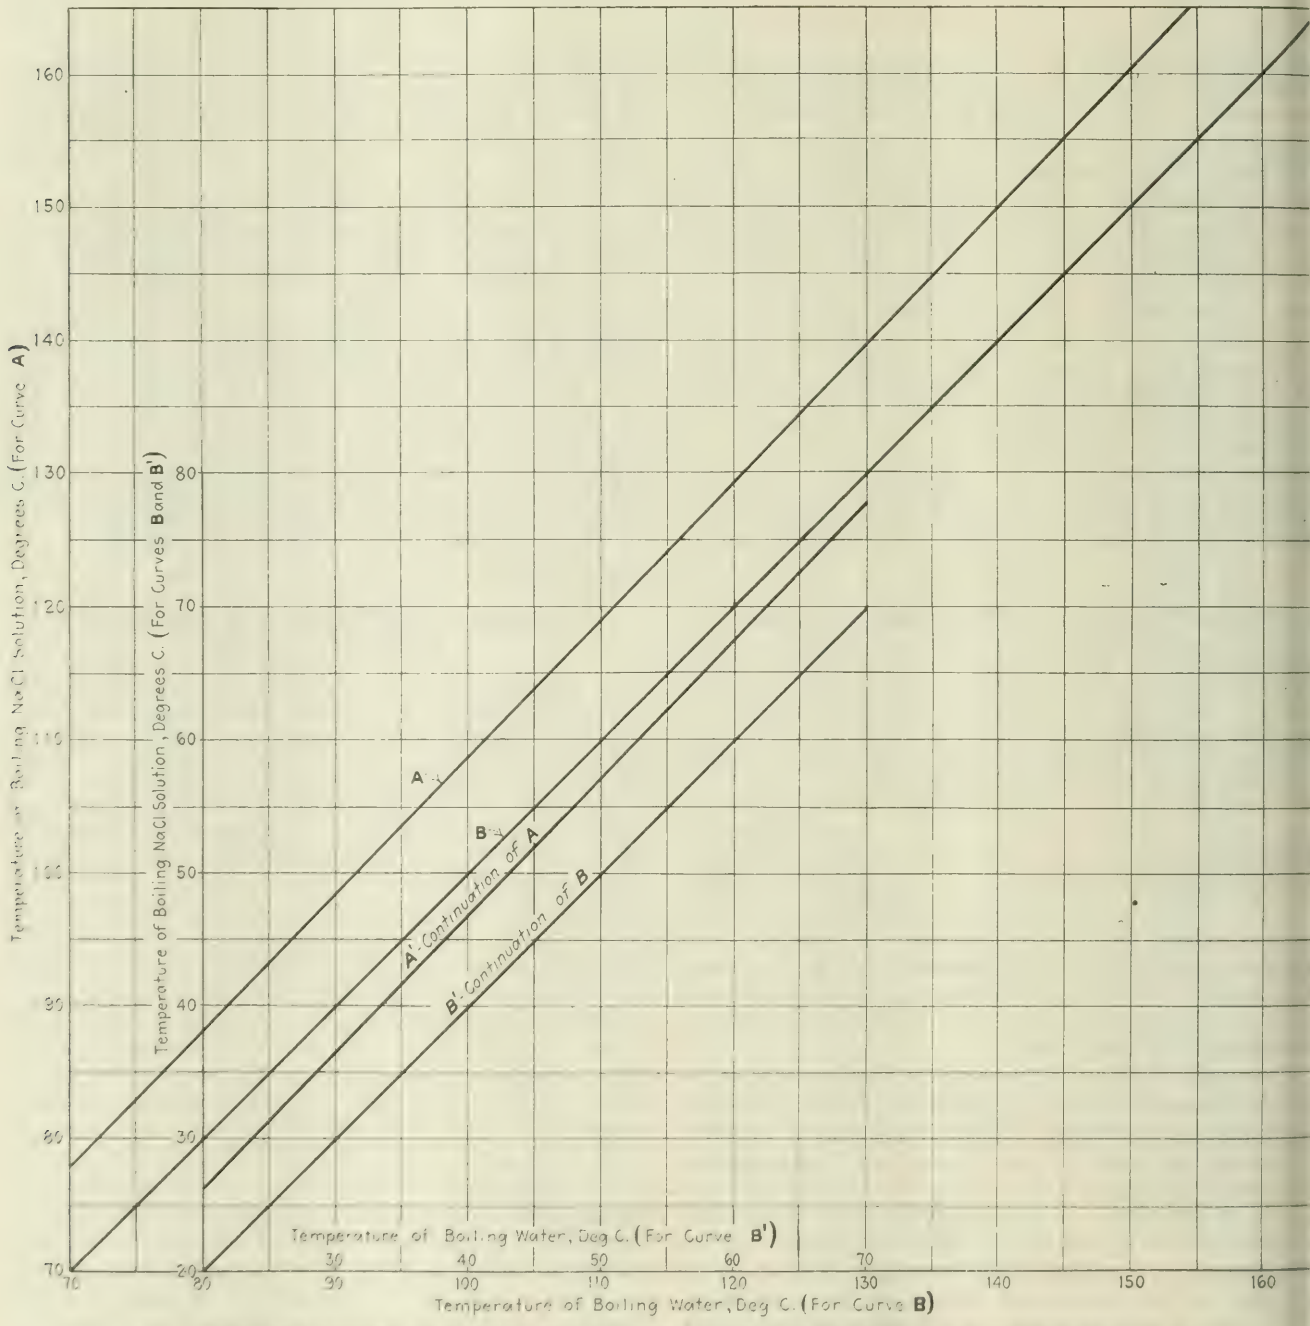

FIG. 1—BOILING POINTS OF SATURATED SALT SOLUTIONS COMPARED WITH TEMPERATURE OF BOILING WATER AT VARIOUS PRESSURES

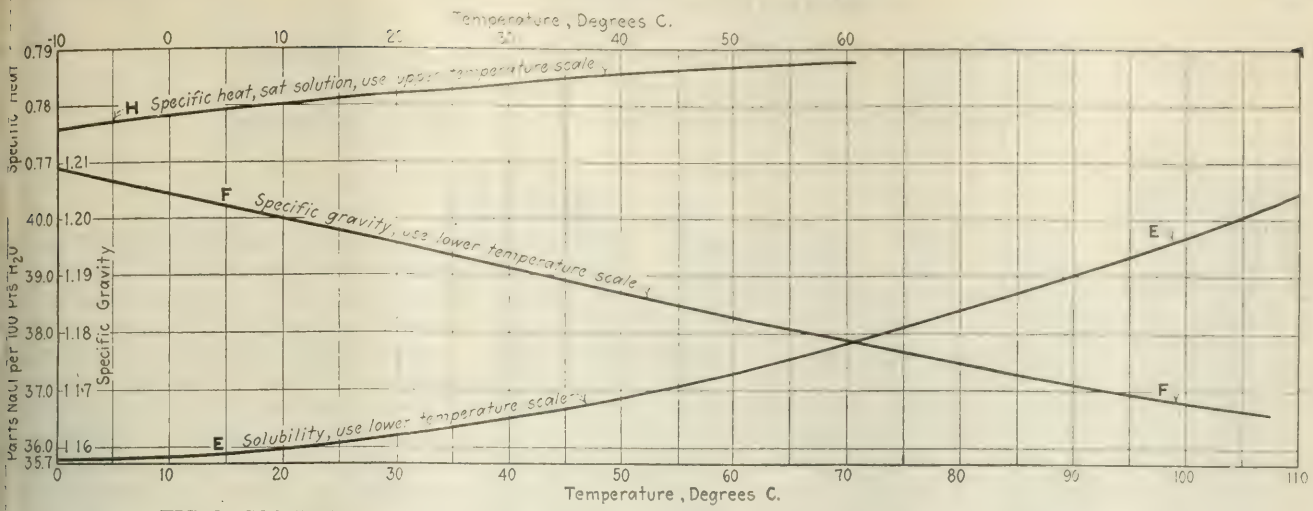

Temperature, Degrees C.
H Specific heat, sat solution, use upper temperature scale
F Specific gravity, use lower temperature scale
E Solubility, use lower temperature scale
Specific Gravity
Parts NaCl per 100 Pts H2O
Temperature, Degrees C.

FIG. 3—SOLUBILITY, SPECIFIC GRAVITY OF SATURATED SALT SOLUTIONS AND SPECIFIC HEAT OF SATURATED SALT SOLUTIONS

B is the rise in boiling point of saturatetd salt solutions. Data from Badger and Baker (*Chem. & Met.*, vol. 23, No. 12, Sept. 22, 1920) plotted as described by Baker (*Chem. & Met.*, vol. 25, No. 25, p. 1137, Dec. 21, 1921).

Composition of Salt Solutions. Parts salt per 100 parts water may be converted to per cent solids by weight, and *vice versa*, by Curve *C* shown in Fig. 2.

Boiling Point of Unsaturated Solutions. Enter Fig. 2 at the lower right-hand corner with composition of solution. Go up to Curve *C*, across to the left to Curve *D*, and then down to per cent rise. Determine the rise of a saturated solution at the pressure in question, and multiply this by the per cent just found. Based on data of Badger and Baker (*loc. cit.*).

Solubility. (Curve *E* in Fig. 3). Use the temperature scale immediately below the curve, and read parts salt per 100 parts water at the left. See Badger and Baker (*loc. cit.*).

Specific Gravity of Saturated Solutions. (Curve *F* in Fig. 3.) Use the same temperature scale as for solubility.

Specific Gravity of Unsaturated Solutions. (Curves *G* in Fig. 4.) This gives specific gravity at three temperatures.

Specific Heat. (Curve *H* in Fig. 3.) Use temperature scale above the curve. (Marks, Mechanical Engineering Handbook, original source not given.)

Authorities. Where no special reference is made, the data were taken from Landolt-Börnstein, Seidel, Comey, or other standard reference work. All the data found were plotted and a mean curve drawn, though in drawing the curve extra weight was given to those data which seemed most reliable.

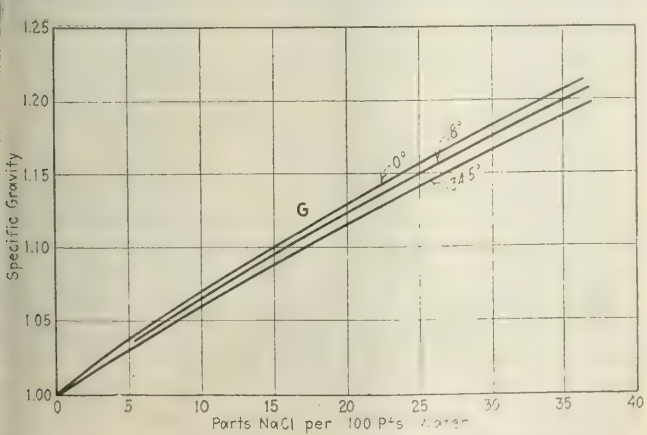

FIG. 4—SPECIFIC GRAVITY OF UNSATURATED SALT SOLUTIONS

Blueprint copies of these curves, assembled on a sheet 18x24 in. in either English or metric units, may be obtained from the author.

The Dye Situation in France

Industrial and technical publications, together with information drawn from local sources, reports Vice-Consul H. S. Fullerton, at Lyons, tend to strike a discouraging note in their survey of the French manufacture of colors. Expectations of extensive exports have not been realized and the creation of customs barriers against German dye imports into France have only partially succeeded in protecting French domestic manufacture, while competition with German and American products in foreign markets is fraught with increasing difficulties.

Import tariffs, whose purpose was the protection of the domestic dye industry, cannot cope with the situation, due to the infiltration of foreign dyes through countries enjoying immunities of minimum tariff and acting as intermediaries. Government subsidy is looked upon in many quarters as at least a temporary solution of the situation, it being estimated that a state grant of 40,000,000 to 50,000,000 francs annually might restore the vitality of these industries.

The alternative plan of government control is generally rejected. The accepted principle of the national necessity, especially in time of war, of active chemical industries of this order gives ground for the belief that some plan may be devised for their artificial stimulation, should such stimulation prove essential.

It might be added that the depression which has been noted in the dye industries would appear symptomatic of industrial chemicals in general in France.

Electrical Resistivity of Carbon

Determinations of the electrical resistivities of a number of different forms of carbon at different temperatures have been made at Seattle, Wash., by the United States Bureau of Mines. Different grades of coke, charcoal and carbon residues were studied. A paper describing the results is being prepared by Clyde E. Williams and Gordon R. Shuck.

Maturing Flour—II

Description of Commercial Equipment for Developing the Optimum Baking Capacity of Flour Through Treatment With a Mixture of Chlorine and Nitrosyl Chloride—Application in Milling Technology

By Frederick L. Dunlap, Sc.D.
Consulting Chemist, Industrial Appliance Co., Chicago, Ill.

In THE first part of this article[1] a brief summary was given of our present knowledge of the principles underlying the process of maturing flour and a parallel was drawn between a flour which had been "matured" and one that had been "aged." It was shown that the most important single factor which influenced the baking capacity of any flour is the intensity of the acidity of the flour and that the optimum baking capacity of a flour is developed when H-ion concentration in the dough is equivalent to a p_H of about 5.

There are many reasons for developing the intensity of the acidity of a freshly milled flour, as has been set forth. That this can be done successfully in a commercial way and that the results are all that have been claimed for them is clearly evidenced by the experience of 10 years of practical application of the Perfect Flour Maturing System.[2]

Although the discussion in Part I of this article was limited to the effects of pure chlorine on flour, there is also used in operating the Perfect Flour Maturing System a mixture of 99.5 per cent chlorine and 0.5 per cent nitrosyl chloride.[3]

Action of Nitrosyl Chloride

Nitrosyl chloride is undoubtedly one of the most effective agents known for treating flour. Experiments have demonstrated that 1 lb. of this reagent will handle 2,500 bbl. of flour in an efficient manner, while it is customary to use chlorine at the rate of 1 lb. for each 30 bbl. It is more efficient than chlorine for whitening flour, but less efficient for increasing the intensity of acidity. At present, however, the commercial distribution of this product is not feasible. It is readily obtained in a liquid state, but metallic containers which will stand up under commercial conditions have not as yet been developed. Liquid chlorine is, on the contrary, easily handled in containers of all sizes, up to and including tank cars, the latter having a 15-ton capacity. Experience has shown that the usual type of containers for liquid chlorine will resist the action of chlorine containing as much as 5 per cent of nitrosyl chloride, so that no difficulty is experienced in handling the mixture used in this system. This mixture of liquid chlorine and liquid nitrosyl chloride is made by the Electro Bleaching Gas Co., Niagara Falls. It is supplied to the trade in 100- and 150-lb. cylinders, and designated as Beta Chlora, to differentiate it from straight chlorine. Shipments are, of course, made in careful accordance with the government regulations for handling liquefied gases, and while many thousand cylinders have been shipped throughout all parts of the United States and to foreign countries as well during the past 10 years, there has never been a single instance of trouble arising from the handling of the containers.

As flour is aged, it becomes of a whiter color. In fact one of the gages used in judging the character of a flour is its natural color. In a natural flour this is not always a reliable test, but it is nevertheless one that is used, and a flour buyer has every reason to expect such a flour to bake to its color. An aged flour with its whiter color bakes better than the same flour freshly milled and, except in an over-aged flour, such flours will show baking quality in accord with the improved color—that is. in an aged flour color is an index of its developed quality.

Now chlorine *per se*, when used to improve the baking quality of flour by increasing the intensity of acidity, does not improve the color of such a flour in keeping with its baking value. Experience has shown that the addition of only 0.5 per cent of nitrosyl chloride improves the color as well as aids in increasing the intensity of acidity, so that this mixture of 99.5 per cent chlorine and 0.5 per cent nitrosyl. chloride simulates the baking as well as the color value of a naturally aged flour. In other words, Beta Chlora produces a flour with a whiter color, but such flours have the improved baking capacity which the color would lead one to expect.

In the handling of flour in the mill to develop the proper intensity of acidity, there are two variable factors to deal with, the character and volume of the flour stream and the quantity of gas to be applied to the flour.

It is always preferable to apply the gas to the primary grades before these are blended to constitute the particular brands that the mill markets. Experience has shown that better results can be obtained by treating the several grades according to the requirements of each, and then subsequently blending percentages of these to form the finished brands, than in attempting to treat the flour after blending has been accomplished.

While the separate streams subjected to treatment in any plant do not vary materially in their character, still they do vary somewhat in character and volume. This calls for equipment which can deliver the gas in a variable flow as conditions require, yet the equipment must be so constructed that each stream can receive only a standardized quantity of gas, which is always below that point where the flour would be overtreated and thereby develop too great an intensity of acidity, a condition similar to that occurring in over-aged flour.

Each Stream of Flour Receives Optimum Treatment

When equipment is installed in a mill, the character of the several streams of flour to be treated is determined in order to give to each the degree of treatment required to produce the optimum effect. This determination is made by a complete chemical analysis and the use of a standard outfit fully equipped, installed in the laboratory of the Industrial Appliance Co. Commercial bakes of the flour are then made, running in parallel the fresh and matured flour, so as to determine the effectiveness of the treatment given. This is

[1] *Chem. & Met.*, vol. 27, p. 174; July 26, 1922

[2] This system is controlled by the Industrial Appliance Co., Chicago, Ill.

[3] U. S. Pat. 1,071,977 covers the use of chlorine; U. S. Pat. 1,654,459 covers the use of the mixture of chlorine and nitrosyl chloride.

peated, if necessary, in order to arn as accurately as possible the xact degree of treatment which will evelop the flour stream in question its optimum baking capacity. With his knowledge, the equipment which installed in the mill is standardized deliver the amount of gas necessary r the proper development of the rticular flour passing through each gitator.

Standardization of the equipment r supplying a constant flow of gas is ffected by means of a silver disk. his disk contains an orifice of such size that with a constant head of gas ack of it, it cannot deliver for use ore than a rated quantity of the gas.

Control Equipment

The simplest plan for discussing the ontrol equipment is to use a single-ontrol machine as the basis. This achine treats but a single stream of our—i.e., the finished flour—and is he type for use in small mills only, ay those of a daily capacity of 50 to 00 bbl. of flour. The equipment is hown in Fig. 1.

Before describing the flow of gas in his type of equipment, it should be ointed out that in the single- as well as the multiple-ontrol machines, the gas, before entering into contact with the flour, is highly diluted with air, thus insuring more even contact and distribution within the agitator.

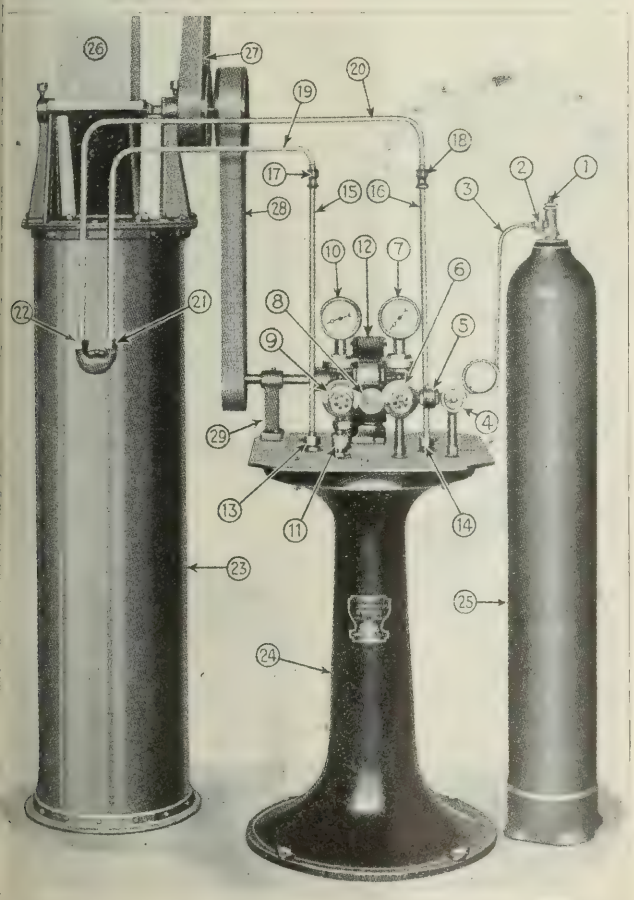

FIG. 1—SINGLE-CONTROL MACHINE FOR TREATING FLOUR

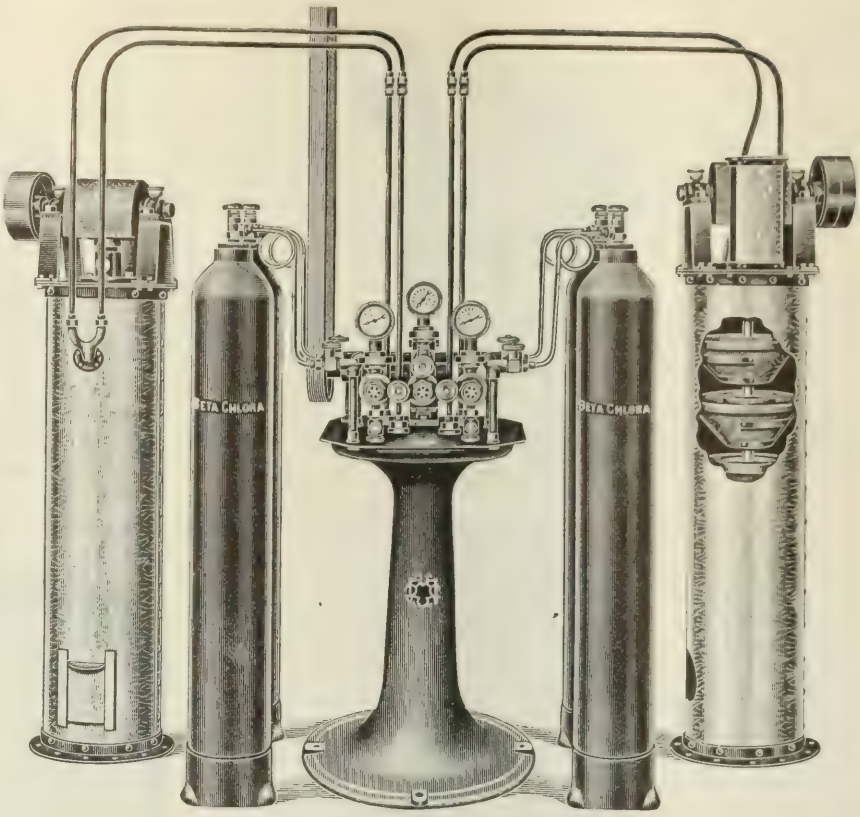

FIG. 2—TWO-CONTROL MACHINE

In the equipment shown in Fig. 1, the course of the gas is from cylinder 25 through valve 1, copper tube connection 3, main connection valve 4, gas strainer 5, initial regulating valve 6, control cut-out valve 8, control valve 9, orifice in silver disk 11, gas line 13, 15, 17, 19 and 21 into distributor in agitator 23.

The air current from blower 12 passes through air line 14, 16, 18, 20 and 22, mixing with the gas in distributor and circulating it through the suspended particles of flour in the agitator.

Gage 7 gives the pressure of gas in the cylinder in pounds and indicator 10 registers the amount of gas (in ounces and fractions thereof per barrel) going to agitator to be applied to the flour.

To start operation it is only necessary to open cylinder valve 1, then valves 4 and 8 and screw in handwheels on valves 6 and 9 until indicator 10 registers the degree of treatment desired. The degree of treatment may be regulated within prescribed limits at the will of the operator, by adjustment of the handwheels on valves 6 and 9.

Irrespective of the pressure of gas in the cylinder, the control apparatus automatically maintains a constant flow of gas at whatever point the operator has adjusted it—that is, while the standardized silver disk in this case will limit the maximum flow of gas, it is within the power of the operator to use a smaller quantity of gas if necessary and desirable.

Fig. 2 shows a two-control machine to which are attached reserve cylinders, so that the treatment may proceed without interruption when empty cylinders are replaced. This machine treats two streams of flour simultaneously. A separate control is provided for each stream of flour, graduated to meet its special requirements. An indicator on each control registers

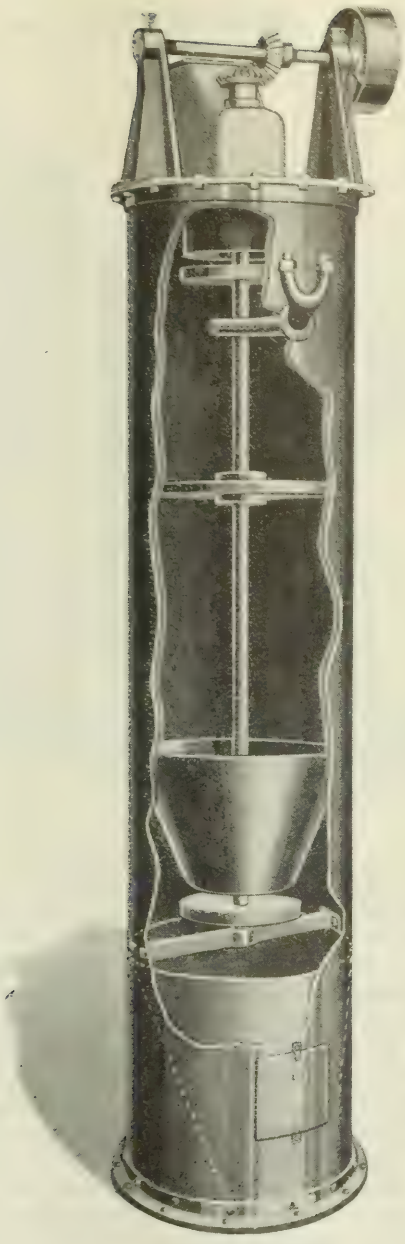

FIG. 3—AGITATOR

the amount of treatment to be given each stream. After passing through the control machine, the active agent is conveyed to the agitator through a $\frac{3}{8}$-in. lead tubing. The air current is pumped from the control machine through a similar tube and mixed with the active agent as it enters the agitator.

This fills the space inside the agitator with the active agent diluted with air and circulated so that it reaches each separate particle of the flour, insuring full and uniform results.

The Agitator

So great are the absorptive properties of flour for the maturing agent that the method of agitation is of paramount importance in obtaining the best results. A standard agitator has been designed to obtain the highest efficiency in results on the product and to provide for the greatest durability in service.

This agitator embodies the following essential features:

1. It suspends the particles of flour in the air in a manner that insures uniform treatment. The flour enters the agitator through a center spout into a feed ring, from where it is distributed in an even spray by means of a revolving disk. Immediately under this disk the gas is forced with a current of air through a perforated hard-rubber siphon, insuring its even distribution and circulation through the suspended particles of flour. In the middle of the treating chamber a hard-rubber wheel serves further to agitate the flour and bring it into more intimate contact with the active agent.

2. It does not admit of any flour lodging, accumulating or remaining in the agitator for overtreatment.

3. The interior of the agitator is constructed of materials which will withstand the action of gas without deterioration. The metal case is lined, a hard-rubber sleeve protects the shaft, and all the interior fittings are of hard rubber.

4. It is adjusted to prevent the escape of gas through the intake or outlet spouts.

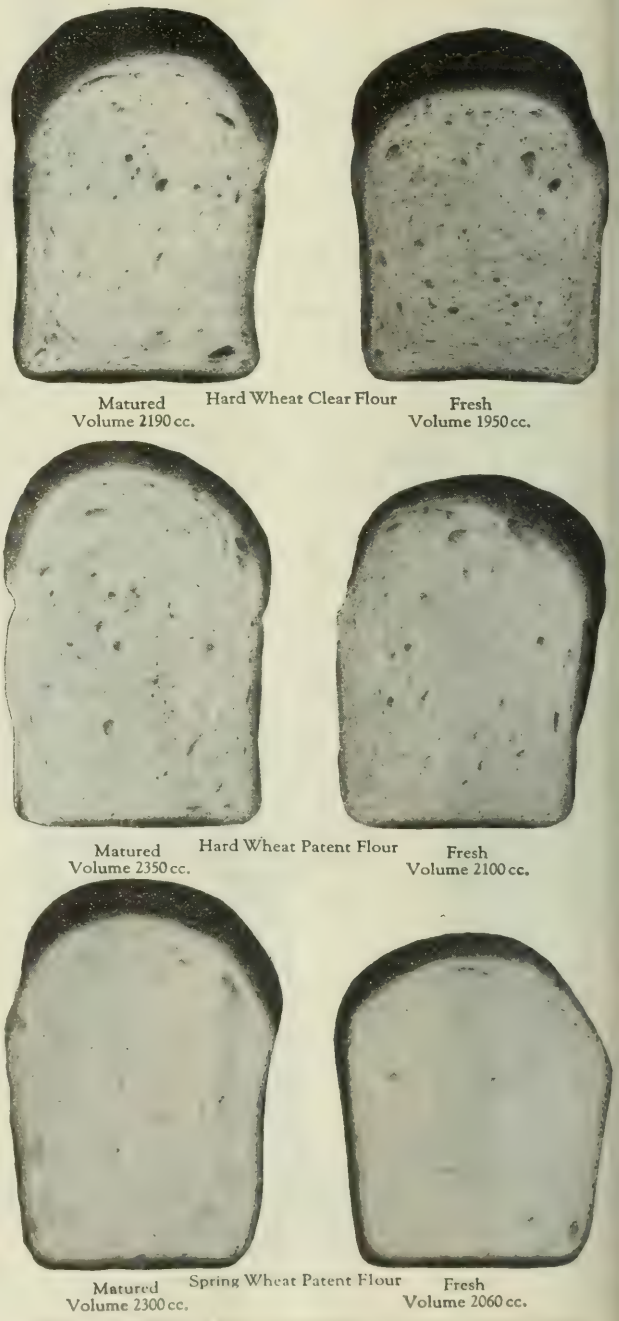

FIG. 4—FRESH AND MATURED FLOUR COMPARED

5. It is easily accessible for inspection or adjustment.

6. It is equipped throughout with ball bearings to provide for easy running with the least amount of attention.

While Figs. 1 and 2 illustrate the general principle of the relation of one part to another in the assembled equipment, it is not essential that this particular arrangement should be followed in the installation in the plant. The agitators can be placed where convenient in the flow of the finished flour ahead of the packers and the control machine can be located where preferred. Its distance from the agitators does not affect results.

The system has been perfected and constructed, both as to materials and arrangement, with the end in view that it may be effective and practical and not require undue care and attention.

Its operation does not entail any discomfort or casualty risk to the operatives, or fire hazard to the proprietors.

Additional controls assembled on the same stand to meet the requirements for the treatment of a greater number of streams of flour are simply duplicates of the initial units which have been described in detail. Standard machines are made with as many as eight separate controls. When there are a greater number of separate streams of flour in any plant, duplicate machines are provided.

Photographic Evidence of Improved Baking Qualities

Fig. 4 gives photographic reproductions of bread made with fresh and matured flour, the latter produced with Beta Chlora. It is difficult in a pictorial way to show adequately the improvement both in color and texture which this treatment brings about.

These were actual commercial bakes, but each flour was handled in accordance with its nature, so as to produce the best loaf of which it was capable and just as it would be handled by any competent baker.

Summary

In the first part of this paper the scientific grounds for the treatment of flour with chlorine were set forth. This treatment increases the intensity of the acidity in the flour to that point where the flour so treated develops its best baking strength. In other words, when chlorine is used properly, the flour takes on those optimum baking properties which develop in an aged flour. Other advantages also result from the chlorine treatment—namely, the stabilizing of this optimum baking value and the development of the color commensurate with the baking value of the flour, just as in the natural aging process. The development of rope is also controlled successfully and, while no great stress was laid on it, the treated flour may be successfully used by the baker with less yeast and sugar. Considering the enhanced quality of the finished flour as well as the oven products produced from it and the fact that the treatment may be applied at a cost not to exceed one cent per barrel, the application of this principle should meet with great commercial success.

The application of the Perfect Flour Maturing System in a practical way extends now over a period of many years. Experience has developed the mechanical features, which have been discussed in the present article, so that the system works with little or no attention on the part of the mill operative. The results claimed for this method of treatment have been substantiated through its years of actual use in the mill and have met with such favor that the Perfect Flour Maturing System is now in mills having a daily capacity of treated flour of over 300,000 bbl. so far as the United States is concerned, and in addition of over 200,000 bbl. in foreign countries, where its use is rapidly extending.

The system, because of the marked beneficial results produced, has become practically an economic necessity, for it brings to the consumer, to the baker or householder, the flour in a condition to render its most perfect service. Because of this it may be truthfully said that the extended use of the Perfect Flour Maturing System has meant a marked advance in the art of milling.

Accidents in Mills and Smelters in 1921

Accidents at all mills and smelters, excluding iron blast furnaces, operated in the United States in 1921 resulted in the death of 27 employees and the injury of 4,494, according to reports received from operating companies by the federal Bureau of Mines. In the preceding year 61 employees were killed and 8,863 were injured.

At milling plants 10,047 men were employed, of whom 4 were killed and 1,214 were injured, as compared with 21 killed and 2,624 injured during 1920. The fatality rate in 1921 was 0.50 and the injury rate was 151.05 per thousand employees, based upon a standard of 300 work days per year, as against rates of 1.31 killed and 164.24 injured the year before. The total working time was 2,411,148 shifts, and represents an average of 240 days per man. The number of men employed represents a reduction of 37 per cent.

At the smelters 18,656 men worked 5,733,969 shifts, an average of 307 days per man, as compared with 24,944 men, 8,741,116 shifts and 350 days per man in 1920. Fourteen men were killed by accidents and 2,129 were injured, or 0.73 killed and 111.39 injured per thousand 300-day workers. The corresponding rates in 1920 were 0.69 killed and 142.33 injured.

At the outside or auxiliary plants operated in connection with the mills and smelters, 9 fatalities and 1,151 injuries occurred among 8,762 employees. The fatality rate per thousand 300-day workers was 1.08 and the injury rate was 138.54, as compared with rates of 1.11 killed and 116.19 injured in 1920.

As compared with the year 1920, reports submitted to the Bureau of Mines for 1921 showed a heavy reduction in the number of shifts worked in nearly every state in the Union. The total number of shifts worked by employees at mills was only 50 per cent of the number worked in 1920; employees at smelters worked only 34 per cent as many shifts, as in 1920; while employees at auxiliary plants worked only 54 per cent of the number worked in 1920.

Solubilities of TNT

Many organic explosives are purified by recrystallizing from solvent, but there is little accurate information on the solubilities. During the past year the explosives chemical laboratory of the United States Bureau of Mines at Pittsburgh, Pa., has prepared a paper for publication giving the solubility of TNT in eleven different solvents. The laboratory is now determining the solubility of tetryl and tetranitraniline.

Production Costs in the Whiting Industry During 1914, 1921 and 1922

AN INTERESTING byproduct of the recent tariff debate in the Senate and an example of an intensive effort accurately to appraise competitive conditions within one of our domestic chemical industries are found in an informal report of the United States Tariff Commission addressed to the chairman of the Senate Finance Committee. Some extracts from that report and the tabulated costs of production are presented in the following paragraphs:[1]

Summary of Conditions in the Industry

The weighted average cost of producing whiting for the first 4 months of 1922 was $18.47 per short ton. This represents a decrease of 9 per cent from the cost of $20.32 in 1921 and an increase of 108 per cent over the pre-war cost of $8.86 in 1914. It was found that the average cost of imported whiting, c.i.f. New York, duty not paid, for the months of April and May was $12.80 per short ton. This cost for imported whiting when contrasted with the average domestic cost in 1922 shows a margin of $5.72 per short ton in favor of the imported product. The difference between the lowest domestic and the average imported cost was $3.99 per short ton.

In connection with costs in the domestic industry, the commission must point out the evident lack of labor-saving devices in the grinding of chalk for the production of whiting. The manufacture of whiting is a comparatively simple operation involving the mechanical operations of grinding, floating with water to classify the production into various grades of fineness, filtering, drying and further grinding of the finished product being packed for shipment. From a mechanical engineering viewpoint there is no reason why the product should be handled from the time the crude chalk enters the grinders until the finished product is packed.

TABLE I—COMPARISON OF PRODUCTION AND IMPORTS, 1914 TO 1922 INCLUSIVE

Year	Imports* Short Tons	Imports* Percentage of Production	Production, Short Tons
1914	1,181	1.8	†66,000
1915	2,693	. . .	. . . . .
1916	1,828	. .	. . . .
1917	1,074	. . .	. . . .
1918	1,223	.	. . . . .

1920	8,875	. . .	. . . . .
1921	8,826	20.6	43,104
1922 (4 months)	‡2,379	11.5	§20,766

* Imports are fiscal years ending June 30 for 1914 to 1917 and from then on are calendar years.
† Figure is low, as does not include production of one firm.
‡ Total imports for first three months plus imports at New York for April.
§ Includes production of two firms for 6 months and does not include output of one firm.

The production of whiting is an industry which has been long established in this country, and with a few exceptions there has evidently been a lack of effort to keep labor costs at a minimum by the installation of modern and improved machinery. This statement cannot be applied to all manufacturers, as there are at least two firms which are working along progressive lines to install continuous apparatus which will result in a saving of labor and a reduction in cost. An examination of the costs by companies (Table III) shows that the labor cost ranged from $2.23 to $5.16 per short ton during 1922. From this wide variation it is apparent that certain manufacturers can reduce costs by improved equipment and design of plant.

[1] *Congressional Record*, pp. 12,382-5, Aug. 15, 1922.

TABLE III—DETAILS OF WHITING COST, BY COMPANIES, 1914, 1921, AND FOUR MONTHS 1922.

(Per short ton)

Company No.	Total Cost	Material	Direct Labor	Total Factory Overhead	Administration and Selling	Packages	Net Price	Profit or Loss

‡ Indicates profit.

Foreign and Domestic Competition

The wide spread between the domestic and imported cost of whiting is in no small part due to existing exchange rates and will decrease as the Belgian and French exchange approaches normal. A factor in favor of domestic product, which is not shown in the cost figures, is the service to domestic consumers. The consumer in dealing with domestic manufacturers has the assurance that in the case of delivery of inferior goods immediate and satisfactory adjustment can be secured from the domestic producer, whereas in the case of the imported product it is evident that such adjustment is considerably more difficult. The point at which the price of imported whiting becomes sufficiently attractive to warrant a change from a reliable domestic source to an imported one cannot be measured accurately. For tariff purposes care must therefore be exercised in basing duties wholly on the spread between the domestic cost and the cost of the imported product landed in the United States.

A comparison of production and imports of whiting shows that imports have increased greatly since 1919. Table I shows a comparison of imports and production from 1914 to 1922, inclusive. In 1914 imports represented approximately 2 per cent of the domestic production and prior to 1920 never exceeded 2,700 short tons. During 1920 and 1921 they approximated 9,000 tons per annum, or about 20 per cent of the domestic production during the latter year. A comparison of imports and production for the four months in 1922 shows that imports were approximately 12 per cent of the domestic output. It is apparent that domestic producers since 1919 have received active competition from imported whiting.

Summary of Costs

Table II compares the costs of whiting for 1922, 4 months, with 1921 and the pre-war year 1914. This table also

TABLE II—COMPARISON OF THE TOTAL WHITING COSTS, 1914, 1921, AND 1922 (FOUR MONTHS)

(Costs are per short ton)

* Insurance only. † Consular fee only.

shows the percentage of total cost represented by the items of material, direct labor, factory overhead, administration and selling, and packages. The total cost for 1922 was $18.47 per short ton. Of this total, $7.39, 40 per cent, was for material; $4.04, about 22 per cent, was direct labor; $3.87, 21 per cent, factory overhead; $3.05, 16½ per cent, administration and selling expenses; and 12 cents, less than 1 per cent, was for packages. The average net price received for whiting during 1922, 4 months, was $22.78 per short ton. A comparison of this price with the total cost indicates that the industry as a whole made an average profit of $4.31 per short ton, or about 23 per cent of the total cost. The cost for 1922 was more than double that of the pre-war year 1914. The material cost for 1922 was more than twice that of 1914; direct labor nearly two and one-half times as much; factory overhead about one and eight-tenths times; administration and selling about two and one-half times the same items in 1914. The average profit per ton of $4.31 in 1922 may be compared with $1.79 per ton in 1914; on the basis of percentage of total cost, however, the profit in 1922 was 23.3 per cent, as compared with 20.2 per cent in 1914.

Table III shows the variation in the cost of whiting according to companies. The costs listed under a given number are those of the same company for the three periods given.

A study of this table shows that the total cost in 1922 ranged from a low of $15.79 per short ton to a high of $21.89, a variation of about 40 per cent of the low cost. The greatest variation in the various items of cost occurs in that of direct labor. This item ranged from a minimum of $2.23 per short ton to a maximum of $5.16, or a variation of about 130 per cent of the low cost. The net price (freights and commissions deducted) received for whiting during 1922 (four months) ranged from $19.16 to $27.66 per short ton.

This table also shows that the average profit during the 4 months of 1922 ranged from $2.11 per short ton to $6.45:

Details of Cost of Imported Whiting

In Table IV is shown the detail of representative shipments of whiting entered at the port of New York—the point at which most of the whiting is imported—during the months of April and May, 1922. This information was obtained from the original invoices on record at the New York custom house. The shipments included in this tabulation represent in quantity a little over one-third of the total imports—1,981 short tons—at the port of New York for the months of April and May. By far the larger part of the whiting entering the United States at this time originated in Belgium, with France ranking second in importance. Very little whiting was imported from England and Germany.

This table shows that the weighted average cost of ten shipments of whiting aggregating nearly 700 short tons was $12.80 c.i.f. New York, duty not paid. This cost may be compared with a cost of $9.36 per short ton at foreign ports packed ready for shipment.

It should be noted that the difference between these two costs is not represented by the items of freight, insurance, consular fees, and other expenses, as it will be seen from the table that these items were not available in the case of all shipments. They are, however, included in the total cost c.i.f. New York in all cases. A study of this table shows that the total cost at New York ranged from $9.89 to $20.52 per short ton.

Legal Notes

By Wellington Gustin

Rules Governing Interpretation of Written Contracts Where Parties Dispute the Agreements

A statement of the rules governing the construction and interpretation of written contracts where parties dispute the agreements is aptly put in a case before the United States Circuit Court of Appeals by Judge Woolley. The case presents an action at law by the General Supply Co. and others against the Marden, Orth & Hastings Co., Inc., and another on a written contract. (276 Federal, 786.)

Verdict of Trial Court

The trial court under its interpretation of the contract directed a verdict in part—for the plaintiff it directed a verdict in the sum of $12,512.18, subject to a possible deduction of $3,000 according as the jury should or should not find this item a proper credit in defendant's indebtedness; and it submitted to the jury a counterclaim of defendants for $50,000, made up specifically of items for raw materials belonging to the defendants in the possession of the plaintiffs at the termination of the contract, valued at $38,416; work in process $2,620; containers, carboys, drums, etc., $7,727. The jury rendered a verdict for plaintiffs for the $12,512 as directed without deducting a $3,000 credit; and for the defendants it gave a verdict for $44,951. Judgment for the amounts followed.

From this judgment the plaintiffs alone sued out a writ of error challenging as insufficient, because of the court's alleged misinterpretation of the contract.

Intention of Parties to Contract Governs Interpretation

The Court of Appeals laid down the cardinal rule that the intention of the parties to the contract governs its interpretation. The law presumes that the parties understood the import of their contract and that they intended what its terms express. When a contract is clear and unequivocal its meaning must be determined by its contents alone; another meaning cannot be added by implication or intendment, but where the language is ambiguous or susceptible of several significations its meaning may be found in the subject matter, viewed in the light of the circumstances under which it was entered into.

Writing, if Reasonable, Is the Contract

Each party to the contract urged that the interpretation given it by the other was such that no reasonable person would ever have entered into the agreement. But the Court of Appeals regarded the language of the contract as expressing a reasonable and workable arrangement such as men in the respective positions of the parties might enter into with reference to the peculiar subject matter and in the light of the unusual circumstances surrounding the transaction. Now, it says, if the writing itself shows a reasonable undertaking of the parties and in this respect shows what they intended and all they intended, that undertaking is the contract. The court cannot go outside of its terms

to find something different, better or even more reasonable. With these observations the court sought the intention of the parties in the circumstances.

Terms of Contract

The important circumstance was that the war was on. Both parties needed production alone to make money. Defendant Chemical company was a large dealer, and, through subsidiaries, a manufacturer of chemicals, with ample capital. The plaintiff corporation, here called the Supply company, had a chemical plant at Perth Amboy, N. J. The stock of this company was mainly owned and the plant was operated by its president and treasurer. The plant was a small affair, costing about $6,000. The financial resources of the corporation, says the court, and the experience of those who conducted its business were not extensive. In short, the Supply company had a plant and little money; the Chemical company had money and wanted a plant. Both wanted more production. This desire was the reason for the contract in dispute, whereby the Supply company undertook for a period of 14 months—later extended to 36 months—to devote its factory exclusively to the manufacture of chemicals from raw materials exclusively supplied by the Chemical company and to sell the manufactured product exclusively to the Chemical company at a profit to the Supply company of 10 per cent on a cost reckoned on a basis agreed upon. Cost as agreed upon included monthly salaries of $150 to each of the operating officers of the Supply company and a monthly amortization of advances by the Chemical company for the enlargement of the plant.

Dispute Over Minimum Monthly Tonnage

Under this contract the Supply company enlarged its plant and increased production. At times the Chemical company showed an inclination to lag and thereupon the Supply company complained to the Chemical company that it was not delivering raw materials and supplying orders sufficient to enable it to make a "minimum monthly output of 7 tons of aniline oil, 4 tons of sulphanilic acid, and 4 tons of Orange II," a production to which the Supply company regarded itself entitled as a base for its minimum monthly profit. Thereupon the Chemical company increased its deliveries and maintained the same quite constantly until July 1, 1918, when on a declining market, it decreased its deliveries and orders. Later the armistice was agreed upon and the Chemical company ordered the Supply company to cease manufacturing on Jan. 1, 1919. The court found that this contingency was provided for in the contract, although the contract had yet 6 months to run and a large amount of unfinished supplies remained in the hands of the Supply company.

The Supply company construed the contract as imposing an obligation on the Chemical company to give orders and deliver raw materials in an amount sufficient to enable it to make a certain minimum monthly profit throughout the term of the contract; and therefore it brought this suit. Wholly different interpretations of the contract were advanced by both parties, resting on one particular paragraph. The correct construction was held to be that the Chemical company "asked for" and thereby promised to take "the products of the enlarged plant which shall be" the monthly tonnage named. The Chemical company was required "to take a specified amount," but the Supply company promised, quite indefinitely, "to use its best efforts so to increase the plant as to produce the quantity asked for." Here the Chemical company urged a lack of mutuality in the contract. The trial court, confining itself to this paragraph, held that as the Supply company had not promised to produce chemicals in any given amount, the promise of the Chemical company to take chemicals in a named amount was without consideration and therefore not enforceable.

Interpretation of Trial Court Found in Error

The Court of Appeals found the trial court in error in restricting its interpretation to this one paragraph. Looking at the whole contract, it says, a consideration for the Chemical company's agreement to take the monthly tonnage named may be found elsewhere in the contract in the Supply company's surrender of its plant and the devotion of its energies exclusively to production for the Chemical company. Therefore it held the contract was not void but enforceable.

Defendant Had Right to Terminate Contract

Yet while this contract partook of a business venture in which the common object of both parties was enlarged production to meet an abnormal market due to war, it was apparent to both that the war would end and with it the market. Therefore the Chemical company in promising to take the increased production of the enlarged plant in the amount of 7 tons plus 4 tons plus 4 tons of different chemicals monthly undertook to do so only "for the present and until further notice." And it gave that notice by ordering production to cease Jan. 1, 1919. The court thought this was not unreasonable and the real intention of the parties, and held that it gave the Chemical company the right to terminate the contract on reasonable notice. Therefore the court held that the Supply company was entitled to receive the total of the monthly differences between profits it would have earned under the contract had the Chemical company supplied it with materials and orders, and the profits it actually received, reckoned from the date of the contract to its termination by notice on Jan. 1, 1919. But it was not entitled to recover profits from this date down to the date named in the contract for its termination, which was about 6 months more. The judgment was reversed and the case sent back for retrial.

Heat Losses of Stored Coal

Calorimeter tests to determine the losses in calories of coal heated in the air for various lengths of time are being made at the Pittsburgh experiment station of the Bureau of Mines. At 125 deg. C. the following heat losses were obtained:

Time of Heating	Per Cent Loss	Time of Heating	Per Cent Loss
30 min.	0.30	3 hr.	1.01
1 hr.	0.26	20 hr.	3.3
2 hr.	0.311	46 hr.	5.7

Samples were heated for various periods of time ranging from ½ hour to 100 hours, and the calorific value determined by the coal laboratory. The results show no regularly increasing loss in heating value as the time of heating increases. The coal samples show a change of weight on heating. First a decrease in weight due to the loss of moisture is observed. The decrease is generally less up to 24 hours, when there is an increase in weight of 0.64 per cent. After heating 100 hours at 125 deg. C. there is an increase in weight of 1.35 per cent and a loss in heating value of 3.02 per cent.

Iron Ore Smelting by Electricity

ALFRED STANSFIELD, Birks professor of metallurgy at McGill University, Montreal, Canada, outlined some of the difficulties in the electric smelting of Canadian iron ores, in an address given Oct. 9, 1922, before the Cleveland Section of the Association of Iron and Steel Electrical Engineers. After tracing the history of the experiments at Sault Ste. Marie, Heroult (Calif.), and those in Sweden financed by the Jernkontoret, it became evident that the design of a successful furnace was no simple matter.

The "elektrometall" furnace, developed by the Swedes, was with some small exceptions the only one in successful commercial operation, but iron ores can be smelted successfully in the "Noble" furnace developed at Heroult and even in a plain, open-top, pit furnace, and these latter furnaces are preferable to the Swedish furnace for the production of gray foundry iron.

Gray Iron for Foundries

Whereas the Swedish furnace operates much like an ordinary iron blast furnace, in that ore reduction and even carbonization of the spongy iron is done by hot CO gas rushing up the stack, low furnaces, of course, must rely almost entirely upon direct contact with solid carbon for reduction and carburization. Doubt has been expressed that the latter will produce the gray iron required for ordinary foundry work in view of two facts: (1) The normal output of the Swedish "electrometal" furnace is white iron, despite its approach to conventional blast-furnace principles; (2) that it was found exceedingly difficult to make "synthetic iron" containing more than 2½ per cent carbon, when remelting steel scrap with granular carbon in an electric furnace. Professor Stansfield was quite positive that these two facts had been stressed unduly. The Swedes make low-carbon white iron, because that metal is more desirable for conversion into steel and wrought iron, and this is the use to which their production is put. Furthermore, synthetic pig iron carburizes so very slowly because the reaction takes place only at the surface of the bath, covered with floating carbon. Keller,[1] in France, showed how to get high carbon by charging the carbon and steel scrap in layers. Therefore a pit furnace would produce high-carbon iron if there remained a slight excess of carbon in the ore column when it finally reached the bottom. This residue of coke or charcoal would rest on the hearth, supporting the granular charge above, and submerged in the molten metal, dissolving therein. Then if conditions were correct—the furnace operating with a "free-burning" arc at high voltage—silicon would also be reduced and the furnace would produce the soft graphitic iron required for ordinary machinable castings.

Excess of Carbon in Charge Is Fatal

An electric furnace is quite sensitive to correct proportioning of the charge. An excess of carbon arriving at the hearth will remain there, and even accumulate if some lean charges are not forthcoming, gradually plugging up the furnace and stopping the operations. It cannot be burned out with more air at the tuyeres, for there are no tuyeres. It simply remains until some solid oxide reacts with it or the metal dissolves it away. On the other hand, a cumulative slight deficiency in carbon (in an electric furnace) means poor reduction, large slag loss and a hard semi-steel, low in carbon and silicon. Even the best of electric smelting furnaces are subject to these troubles—a low pit furnace has something the better of the Swedish shaft furnace, in that a much shorter time is required for a corrective charge to work its way to the seat of the trouble.

Experience with several furnace designs indicates that iron is smelted best when the arc is free burning—i.e., immersed in the charge but slightly—and surrounded by an incandescent crater of flame and gas. Deep immersion diffuses the heat because many more paths through the ore charge are offered by which the current can leak from electrode to electrode. Short circuits are then frequent and the voltage must be reduced; partial fusion and reduction occurs at many points, and the charge has a tendency to "hang up." Even worse conditions result if the electrodes are forced still lower into the molten slag or metal, when the furnace becomes completely short circuited.

Economic Considerations

Professor Stansfield pointed out that inherently electric smelting demanded cheap power. Two-thirds of a ton of fuel per ton of pig iron may be saved, but in general the electric energy required (½ hp.-yr.) costs more than that much coke, although it may cost less than the amount of charcoal that would be saved. It follows that the electric furnace is unlikely to replace the coke blast furnace, though it has successfully replaced the charcoal blast furnace in Sweden. It was his opinion, also, that electrical energy was far too valuable a commodity to be used permanently in such a crude operation as ore smelting. It could be done only on the "outposts of civilization," where the power might easily be developed long before the demands of culture and industry could absorb it. As population increased, their multifarious needs would warrant them paying a far higher price for electricity, and ore smelting would be discontinued. This is not a particularly bright outlook for the method, however. The speaker said the reason, in his opinion, why electric pig iron was not now being produced in Canada was on account of their high labor and material costs and a lack of a special market which could be filled by that special quality of iron. But is it not true that labor and materials are always high in the outposts of civilization and there is never a local market for special irons and steels?

Professor Stansfield considered that there was a field for the application of electric smelting of iron ores on a limited scale at points where conditions were especially favorable, but that any large-scale development of electric smelting must form part of a process in which the ore would be reduced to the metallic state in fuel-fired furnaces at a low temperature before entering the electric melting furnace for the production of steel.

The Grignard Reaction and Organomagnesium Compounds

Dr. C. J. West of the National Research Council some time ago compiled a very complete bibliography of articles relating to the Grignard reaction. This bibliography and a discussion of the reaction are now available as No. 24 of the reprint and circular series of the National Research Council. The report is exceptionally complete and splendidly indexed by compounds and by authors. The report is for sale by the Council at $1.50.

New Invention Eliminates Accidental Explosion in Gas Mixtures

By Dr. H. C. P. Weber
Research Laboratory, Westinghouse Electric & Manufacturing Co.

THE accumulation of explosive gas mixtures in inclosed spaces is of frequent occurrence, and accidental ignition of these explosive mixtures in public places has led to disastrous results.

Thus the explosion of sewer gases in city sewer systems is not at all infrequent. So also occasional explosions are reported from public service tunnels and underground systems. The same problem presents itself as a result of gas mixtures which accumulate from various causes in closed vaults containing control apparatus, electrical or otherwise, in transformers and in similar apparatus.

Nature of Explosive Gases

The gases accumulating under these conditions may arise from a variety of causes. In general, however, they are essentially hydrocarbons (principally CH_4 and related compounds), with occasional admixtures of hydrogen and carbon monoxide. Thus the accumulation in sewers may be CH_4 from fermentation or, at times, gasoline vapors. In the case of other underground systems in streets, there is some possibility of the accumulation of gasoline vapors or of illuminating gas from adjoining mains or, in unusual cases, gases arising from the accidental destruction of the organic insulating materials commonly used. In systems where considerable quantities of lubricating or insulating oil are used, a slight accumulation of explosive vapors may arise from these materials themselves.

A similar problem presents itself in the gases accumulating in mines which resulted in authoritative and exhaustive research by the Bureau of Mines on this subject. Here the quantities of gas are so enormous and the spaces to be controlled are so vast that little can be done beyond obtaining the best possible ventilation. In more limited spaces, however, some preventive measures have been taken, such as the use of fire-snuffing vapors, chloroform and carbon tetrachloride; but these measures have been rewarded with only a limited amount of success. The use of CO_2 to dilute the explosive mixture below the explosion point has been suggested, but this requires an entirely impracticable amount of CO_2. Moreover, one of the essential requirements to obtain safety is occasional attention only; and under these conditions the use of CO_2 becomes unsatisfactory.

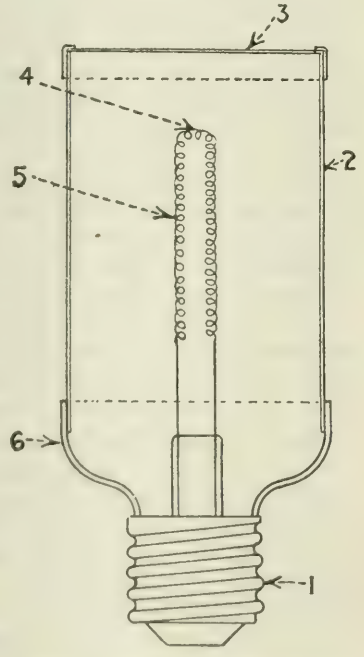

FIG. 1—OUTLINE DIAGRAM OF LAMP

The method to be described here eliminates the danger of explosion by continuously removing the explosive mixture itself—that is, by burning it up more rapidly than it can accumulate. In order to do this the gas must be oxidized at a temperature considerably below that at which the explosive wave is propagated—that is, below the explosion point. It has been possible to do this by the use of an oxidative catalyst finely distributed over a porous surface. A description of the principle of this operation, and some of the results attained, follows:

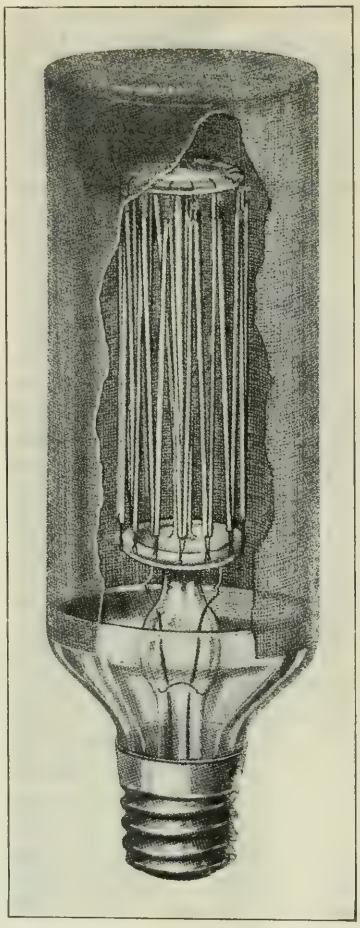

FIG. 2—LAMP WITH SECTION OF WIRE SCREEN CUT AWAY TO SHOW FILAMENT

In the diagram, 1 is a lamp base of the ordinary type which may be screwed into any ordinary lamp socket for the purpose of making connection with a 110-volt circuit. The leads are brought in from the base in the standard fashion through a glass insulating member; 6 is a glass member supporting 2 and 3; 2 and 3 consist of a fine mesh wire screen which is intended to prevent any flame which may form in the interior from striking through to the outside, according to the well-known Davy principle. As a matter of fact, the device is so designed that the possibility of formation of a flame in the interior may be neglected. The bulk of the results described in the succeeding were obtained with the bare and unprotected filament, and the wire gauze is in the nature of additional security. The filament itself, 4 and 5, is shown in the diagram in the simplest form of a coil. In practice there are a number of variations more suitable for special purposes, either consisting of a solid porous cylinder internally heated or of wires sheathed in porous tubes and arranged to form a hollow cylinder.

The essential feature in the whole device is the application of a catalyst to a considerable porous surface, and the control of the resistance of the whole system so that it normally takes on a safe and effective operating temperature. The temperature we have found most satisfactory to use has been between 600 and 800 deg. C. using a platinum catalyst. The best temperature of operation depends somewhat on the catalyst used and the results have varied with various compositions used as catalysts. For this discussion the results with platinum may be taken as typical.

Results Obtained With Platinum Catalyst

The following results give the temperatures (measured by the optical pyrometer) necessary to explode a mixture of 10 parts of air to 1 of natural gas.

Time	Amperes Through Lamp	Deg. C.	
10 min.	1.00	925	No explosion
5 min.	1.05	955	No explosion
20 sec.	1.10	995	Exploded
.....	1.15	1,080	Immediate explosion

These tests were repeated with the natural gas in various mixtures, and the results uniformly showed that under these conditions, filament bare and unprotected, a temperature of nearly 1,000 deg. C. was necessary to produce explosion.[1]

With these preliminary results at hand, the next set of determinations had to do with the operating efficiency of the device as a gas consumer.

RATE OF GAS CONSUMPTION. BARE WIRE, NO CATALYST
2,500 c.c. Air. 250 c.c. Natural Gas

Time	Filament Temp., Deg. C.	CH_4 Burned Per ½ Hr., Per Cent
2½ hr.	780	4
½ hr.	850	11
½ hr.	940	26
2 min.	940	.....
2 min.	960	62 (no explosion)
½ min.	1,000	.....

Results With Other Catalysts

A further series of experiments was carried on to determine the effect of a number of well-known oxidation catalysts. These were carried out by running up the temperature for each catalyst and determining the rate of gas consumption at successive steps 400, 500, 600 and 700 deg. C. Detailed discussion of these results is reserved for some future date. It may be said, however, that while the order of effectiveness did not change essentially for the various catalysts, certain catalysts were relatively more effective than others at low temperatures—that is, change in temperature did not affect all catalysts to the same degree. Further work is needed to discuss this phase satisfactorily.

As examples of the final results obtained, the following values are given:

RATE OF GAS CONSUMPTION. COVERED WIRE + CATALYST
2,500 c.c. Air. 250 c.c. Natural Gas

Catalyst	Time	Filament Temp., Deg. C.	CH_4 Burned Per ½ Hr., Per Cent
Ca-Cr	½ hr.	700	80.4
Pt (A)	½ hr.	700	93.0
Ba-Mn	½ hr.	700	78.0
Pt (B)	½ hr.	700	97.0

The best of these results shows that with the volumes as given, 97 per cent of the combustible constituent, methane, of a mixture in the proportions for complete combustion and highly explosive, can be burned out in ½ hour. The temperature at which this is possible is about 300 deg. C. below the ignition point.

Of course a similar result could be attained at the expenditure of greater time and at a lower temperature. However, throughout an extended series of tests with numerous gases and a variety of lamps, we have never obtained ignition of the most highly explosive vapors and we consider 700 deg. a safe temperature for the device as constructed.

Results With Various Gas Mixtures

Some of the results obtained[2] at various times, based on 5 cu.ft. of gas, or 136 liters, and using the lamp of the most effective type have been as follows:

Pittsburgh natural gas	.6%	91.4 air	43% in 24 min.
Rich coal gas	8.6%	91.4 air	40% in 24 min.
Lean coal gas	10.0%	90.0 air	57% in 24 min.
Hydrogen	10.0%	90.0 air	56% in 10 min.
Hydrogen	15.0%	85.0 air	76% in 10 min.

The astonishing result is that the device functions even in a 10 or 15 hydrogen air mixture. This is probably the most severe test that could be made. The rate of consumption is enormously increased in this mixture, as may be noted. For mixtures of air and hydrogen (submarines and the like) we recommend a type specially designed for this purpose.

In conclusion it may also be stated that when actively functioning in an explosive mixture, the temperature of the filament is somewhat higher due to the heat of reaction. This is readily discernible and the temperature drops again when the combustible gas is exhausted, giving a qualitative indication of the presence of explosive vapors. By the use of a thermocouple junction this indication may be made to be self-recording and capable of accurate measurement.

Use of Oxygen in Metallurgical Operations

Use of oxygen in connection with the enrichment of the blast in the blast furnace and in practically all phases of pyrometallurgical work will furnish the key to success in the further development of such metallurgical operations, according to Dr. F. G. Cottrell, formerly director and now consulting metallurgist of the United States Bureau of Mines, who first directed the bureau's attention to this subject. Through this enrichment process, it is hoped to increase the efficiency of metallurgical operation with a resultant production of metals at lower cost and possibly the use of lower grade ores.

The Bureau of Mines now has outlined plans for two studies which will be carried on simultaneously. The first will cover the present-day processes for the production of oxygen, in order to determine the feasibility of attempting to produce oxygen, or oxygenated air, in such amounts and at such a cost as to permit of its use in metallurgical operations. The second study will be devoted to the feasibility of using oxygen, or oxygenated air, in metallurgical operations.

Because of his interest in this investigation, M. H. Roberts, vice-president of the Franklin Railway Supply Co., was asked to select an advisory committee to work with the Bureau of Mines, and to act as chairman of this committee. The committee will consist of Dr. F. G. Cottrell, director of the Fixed Nitrogen Research Laboratory; Prof. W. L. DeBaufre, chairman of the mechanical engineering department of the University of Nebraska; Dr. D. A. Lyon, chief metallurgist of the Bureau of Mines; Dr. R. B. Moore, chief chemist of the Bureau of Mines; Dr. R. C. Tolman, professor of physical chemistry and mathematical physics, California Institute of Technology; J. W. Davis, mechanical engineer of the Bureau of Mines; F. W. Davis, metallurgist of the Bureau of Mines; Frank Hodson, president of the Electric Furnace Construction Co., and P. H. Royster, assistant metallurgist of the Bureau of Mines.

Previous to the war, some work was done in Belgium on the enrichment of the blast with oxygen in connection with the smelting of iron ores in the blast furnace.

[1] An exhaustive study on the temperatures of glowing wires necessary to explode various gas mixtures is found in Bureau of Mines Bulletins 52 and 131, Tech. Papers 23, 28 and 75.

[2] For a number of the determinations on various gas mixtures we are indebted to the courtesy of the Pittsburgh Station of the U. S. Bureau of Mines.

Synopsis of Recent Chemical & Metallurgical Literature

Nitrogen in Iron and Steel

A review of methods for determining nitrogen in steel and cast iron and a comparison of the amounts of nitrogen found by previous investigators in the several classes of irons and steels are given by F. Wüst and J. Duhr.[1] Further on in their report they give a modification of the usual method of analysis for nitrogen, describe the preparation of a number of nitrides, and give the results of an investigation of the amount and the behavior of nitrogen in iron during the puddling process and in open-hearth, electric and bessemer steels.

All reliable methods for determining nitrogen in steel yet found depend on the conversion of the nitrogen to ammonia by the action of a suitable solvent. This ammonia, recovered from the solution by distillation with an alkali, is determined by a colorimetric (Nessler) or a titrimetric (alkalimetric or iodometric) method. The Nessler method was condemned by Wüst and Duhr because the color of the Nesslerized distillate is modified by the amines during the solution of cast irons. In the analysis of cast irons it was also impossible to determine satisfactorily the end point in the iodine titration. A very sharp end point and satisfactory results were obtained by titrating the ammoniacal distillate with 0.01 normal sulphuric acid using an ether solution of iodeosin as the indicator. Thirty c.c. of this indicator solution is shaken in a 250-c.c. flask with the ammoniacal distillate. Two layers separate, the lower one colored a deep rose. This color fades on titrating with sulphuric acid and is completely lost with the slightest excess. Results for nitrogen in cast irons were from 50 to 100 per cent higher by the iodometric titration than by the iodeosin method. Hydrocarbons which interfere in the iodine titration are shaken out in the ether layer in the new method and thus do not influence the results.

Nitrides of several metals and ferroalloys were prepared by heating the finely powdered materials in N at 900 to 1,025 deg. C. for a number of hours and the product analyzed by the iodeosin method. Results are given in Table I.

TABLE I—ABSORPTION OF N_2 AT 900 TO 1,025 DEG. C.

Metal	N_2 by iodeosin method
Pure Fe	0.02 per cent
Pure Cr	9.81 per cent
Mn (97 per cent)	6.60 and 7.36
Ni	none after 3 hr.
Mo	none after 6 hr.
47 per cent ferrochromium	0.92
86 per cent ferromanganese	0.78
25 per cent ferrotitanium	1.52
10 per cent ferro-aluminum	more than 3
25 per cent ferrovanadium	more than 1
83 per cent ferrotungsten	0.0118
22 per cent ferrophosphorus	0.0179

Wüst and Duhr conclude with an investigation of the amount and behavior of nitrogen in wrought iron, and open-hearth, electric and bessemer steels. Nitrogen in puddled iron increased in proportion to the duration of the heat. The pig iron charge of the heat for which complete data are given contained 0.0009 to 0.0013 per cent nitrogen, while the finished material held from 0.003 to 0.004 per cent.

The changes in nitrogen content during the progress of open-hearth and electric induction furnace heats are traced for one heat of ingot iron, five heats of carbon steel and three heats of chromium steel. Each of these steels was made by a duplex process—a preliminary refining in an open-hearth furnace by the Talbot process, followed by the final refining in a Röchling-Rodenhauser induction furnace. The nitrogen content of the metal of the bath at the start of the open-hearth refining period was about 0.002 to 0.003 per cent in all heats. At the close of the open-hearth refining the nitrogen content was approximately the same as at the beginning, although in some of the carbon steel and chromium steel heats the nitrogen value had passed through a maximum during the progress of the heat and then fallen off to its original value.

During the electric furnace refining the nitrogen in the ingot-iron heat increased slightly to a final value of 0.004 per cent. The nitrogen content of the carbon and the chromium steels increased very considerably during the electric furnace refining; the plain carbon steels finished with 0.009 to 0.012 per cent and the chromium steels with 0.005 to 0.008 per cent N. In heats selected as typical by the authors, plotting the nitrogen content of the bath against the duration of the heat shows very strikingly the influence on the nitrogen content of the various additions to the bath. Recarburization with coke at once increased the nitrogen content of the bath five or six fold—for example, from 0.002 to 0.010 or 0.012 per cent. Additions of a lime-clay-fluorspar slag mixture decreased the nitrogen content, but the subsequent addition of ferrosilicon near the close of the heat again raised the nitrogen content to nearly or quite its maximum value for that heat.

The behavior of nitrogen in basic bessemer practice was determined in about ten heats from each of six different works. From each heat were taken samples of the charge, of the steel before deoxidation, after deoxidation, and after the casting of the last ingot. The nitrogen in the pig iron charge was from 0.0007 to 0.0013 per cent. The steel before deoxidation contained from 0.0109 to 0.0210 per cent nitrogen, and this value was not changed by deoxidation by either solid or liquid deoxidizers.

Qualitative tests for nitrogen in iron as cyanide were negative. The theory that silicon may be a nitrogen carrier in iron does not seem to be correct, or there would be higher nitrogen in acid than in basic bessemer metal, a condition which is not in accordance with fact. From their success in introducing nitrogen into pure iron by heating in nitrogen gas at 900 to 1,100 deg. C., as well as from further successful attempts at nitrogenizing charcoal iron and basic bessemer pig iron by leading dry nitrogen through the molten metal, Wüst and Duhr conclude that in the bessemer blow, nitrogen from the air blast unites directly with the iron.

[1] *Mitteilungen aus dem Kaiser-Wilhelm-Institut für Eisenforschung*, vol. 2, pp. 29-57; reviewed at length in *Stahl und Eisen*, Aug. 17, 1922, pp. 1295-6.

A Novel Salvaging Operation

The *Hercules Mixer* for September, 1922, describes the novel method used for wrecking four of the sulphuric acid-concentrating units. The building contained five lead pan concentrating units which were used during the war for the concentration of denitrated sulphuric acid. It was decided to tear down four of the units and the building which housed them. Accordingly, the structure was cut away between the fourth and fifth units and a ⅞-in. steel cable approximately 200 ft. long was attached to a roof truss. The other end of the cable was attached to a steam locomotive, and after two or three attempts the building gave way and collapsed.

The lumber was used as fuel under the nitric acid retorts. The nitric acid plant happened to be located near to the old sulphuric acid recovery building, so a portable saw was set up near the wreckage and the lumber sawed up into suitable lengths for use in the nitric acid furnaces.

Feldspar Production in New Hampshire

A recent report of investigations of the Bureau of Mines by Raymond B. Ladoo describes one of the important recent developments in the feldspar industry—namely, the rapid rise of New Hampshire as a feldspar-producing state. The unusual size and purity of the deposit now being worked in Keene and the improved methods of mining and milling used have been responsible for this situation. In the spring of 1921 the Keene Mica Products Co., of Keene, N. H., began the production of feldspar from its property in Gilsum, N. H., which had long been operated as a mica mine. The purity of the feldspar at once attracted favorable attention and the production of crude ore rapidly increased. The feldspar is pure and

shows little or no evidence of alteration. It occurs in large crystals and masses with relatively small quantities of crystallized quartz. There is little or no graphic granite or intergrowth of feldspar and quartz. The quality of the feldspar is altogether unusually good.

Milling Operations

The crude ore is unloaded on the floor of the mill and shoveled into a 9x6-in. manganese steel jaw crusher of a special type, which in one operation will crush large lumps to about ⅜-in. size. The ground material is raised by means of a bucket elevator to a 35- to 40-ton bin, and delivered to a disk feeder to a Hardinge mill. The finely ground material is conveyed by a bucket elevator and a short belt conveyor to a 14-ft. Emerick air separator. The fine material is conveyed to a railway car or to storage while the oversize material is returned by a belt conveyor to the disk feeder. The estimated capacity of the plant is 1½ to 2 tons per hour. The success of this method of milling following the general method outlined by the Bureau of Mines offers definite proof that feldspar can be ground continuously and sized by air separation, at the same time making a better product, at a lower cost than is common in batch grinding in "dump cylinders."

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Tanning Extract From Quebracho and Waste Sulphite Liquor—Quebracho extract is completely soluble in waste sulphite liquor yielding a liquor which has a tanning value somewhat in excess of the sum of the tanning values of the components. This liquor differs materially from sulphited quebracho extract prepared with the aid of sodium sulphites, as the fresh waste liquor contains only a trace of free sulphurous acid or sulphites. The waste liquor is used just as discharged from the digestor—that is, in the form which is usually called light liquor to distinguish it from evaporated preparations. Various efficient tanning agents can be made from the light liquor by concentration and by other treatment, but the light liquor as it comes from the digestor and without treatment has but little tanning value. If further acidulation of the light liquor is desirable, commercial sulphonic acids containing an aromatic group appear to function better than most other acids. As an example of the preparation of extracts according to this specification, 5 per cent of a sulphonic acid is added to a mixture of equal parts by weight of commercial quebracho extract and light liquor. Upon warming, a clear extract is obtained which can be diluted as desired with water without precipitation of tans. (1,430,477. John K. Tullis, of New York, N. Y., assignor to Fulcra Tan Co., of Irvington, N. J. Sept. 26, 1922.)

Chlorination of Gaseous Hydrocarbons — An essential feature of the invention consists in effecting the chlorination of the hydrocarbons in the gaseous phase and under anhydrous conditions, and thereafter isolating from the reaction mixture the unchanged hydrocarbon, the chlorine derivatives thereof, and the halogen acid, or some of them, by liquefaction methods comparable to those applicable for the separation and recovery of the components of air or other mixtures of so-called fixed gases. (1,422,838. George O. Curme, Jr., assignor to Carbide & Carbon Chemicals Corporation. July 18, 1922.)

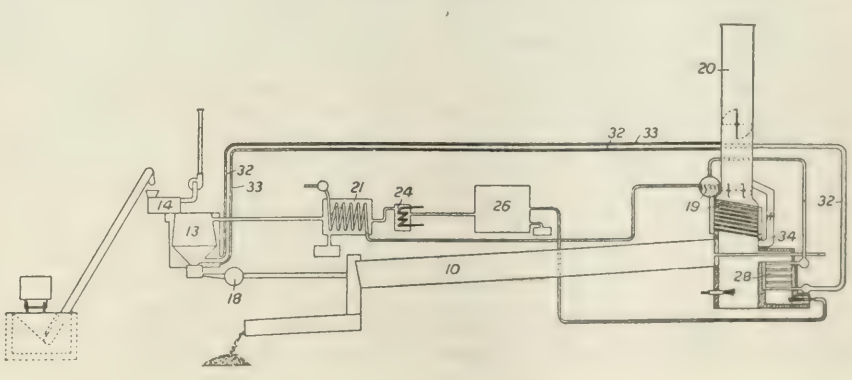
Tanning With Pyrophosphates and Alum—In tanning with solutions containing sodium pyrophosphate, alum and salt, as described in U. S. Pats. 1,039,150 and 1,191,527, it has been found that successful commercial operation requires careful regulation of the temperature, preferably between 95 and 105 deg. F. Exposure for any length of time to temperatures above 107 deg. F. causes deterioration, the leather lacking tensile strength and becoming more or less brittle or "grain-cracky." (1,427,221. Ernest Wyndham Merry, of Sheffield, England, assignor by mesne assignments to Pyrotan Leather Corporation, of Wilmington, Del. Aug. 29, 1922.)

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Building, Chancery Lane, London, England.

Cement—The apparatus described comprises a kiln plant and a process for operating it, in which the firing of the kiln is effected by the coke residue from a carbonization plant working in conjunction therewith. In one form of apparatus, the waste gases from the rotary kiln 10 are utilized in a low-pressure boiler 19, the steam from which is passed to an independently fired superheater 28, and thence to a continuously operating low-temperature distillation retort 13 having a fuel preheater 14. The gas from the retort is passed through a condenser 21, acting as a feedwater heater for the boiler, a cooler 24, and byproduct recovery plant 26, and may then be used for firing the superheater 28 and supplying additional heat to the boiler 19 when required. The solid residue from the retort is pulverized while still hot, and is fed to the kiln by the fan 18. When additional fuel is required for the kiln, the powdered residue, with or without other powdered raw fuel, is mixed with the residual oils from the gas and fed to the kiln in colloid form. The waste gases from the kiln may be bypassed round the boiler through the flue 34. The steam pipe 32 leading from the superheater to the retort is jacketed by a flue 33, through which waste gases from the chimney 20 are passed to a jacket round the retort and thence to the preheater 14. In a modified form of apparatus the boiler and superheater are independently fired and the waste gases of the kiln are utilized for heating the feedwater only. The hot gas from the retort is passed through three heat interchangers in series which act respectively as a feedwater heater, a vaporizer and a superheater, and the steam from the last is passed to the superheater in connection with the main boiler. (Br. Pat. 181,811. E. G. Weeks, Northumberland. Aug. 16, 1922.)

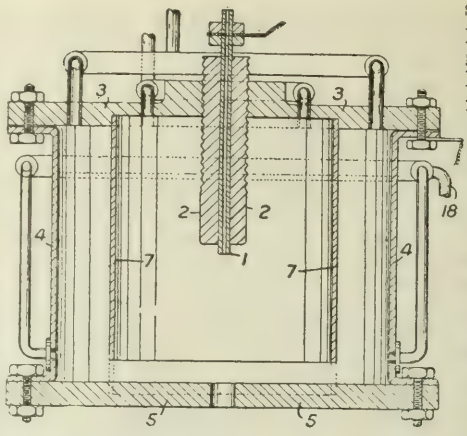
Metallic Powders—Metallic powders for industrial and decorative purposes are obtained by electrolysis using an anode of the required metal, the current density being chosen so that the metal is deposited on the cathode in a finely divided, non-coherent and non-adherent crystalline form; the electrolyte is passed rapidly between the electrodes so as to carry away the powder, and then passes through a separator and, if necessary, a regenerating vat, from which it is returned to the cell or cells by a pump. The current density may be 20 amp. per sq.ft., and the electrolyte velocity 10 ft. per sec. The electrodes may be $\frac{3}{32}$ in. apart. The cathode may be of aluminum or copper and may be stationary or may revolve or reciprocate. The powder may be separated from the electrolyte centrifugally or by levigation or filtration, and is washed, dried and, if necessary, polished. In obtaining bronze powder from scrap metal, the electrolyte may be a saturated solution of copper sulphate together with sulphuric acid. Thirty-six cells in series are used, with a current of 1,000 amp. and a pressure of 36 volts. A 50-volt generator is used, driven by a motor which also drives the pump



and the washer, polisher and drier. (Br. Pat. 181,831. W. M. Gillespie and P. Buckley, London. Aug. 16, 1922.)

Bleaching Powder — Compounds of calcium hypochlorite and calcium hydrate are stabilized by washing to remove calcium chloride and by subsequent drying at temperatures up to 110 deg. C. either *in vacuo* or at ordinary pressure. The products thus prepared, which comprise compounds containing 1 to 4 molecules of calcium hydrate in combination with one molecule of calcium hypochlorite, are stated to possess various advantages over ordinary bleaching powder, in that they remain almost unaffected at elevated temperatures at which bleaching powder would be decomposed, have a higher percentage of available chlorine and possess only a faint smell. In an example, 1 cu.m. of chlorinated milk of lime containing 145 grams of available chlorine per liter is stirred with 60 kg. of calcium hydrate, after which 128 kg. of moist salts is separated from the mother liquor. The product, after drying at an elevated temperature, weighs 100 kg. and contains 42 per cent of available chlorine. In another example, a lime sludge containing 100 parts of quicklime and 250 parts of water is chlorinated by stirring in a closed vessel until 85 parts of chlorine have been taken up. The product is freed from the calcium chloride mother liquor and the pressed cake dried in a steam drying oven. The product contains 50 per cent of available chlorine and in this case contains the compound comprising one molecule of calcium hydrate in combination with one molecule of hypochlorite, in addition to that containing twice this quantity of hydrate. The proportions of calcium hydrate and chlorine may be varied so that other products of higher basicity or, on the other hand, mixtures of basic hypochlorite with neutral hypochlorite may be produced, as desired. The compounds are suitable for use in bleaching and disinfecting. (Br. Pat. 182,921. Chemische Fabrik Griesheim Elektron, Frankfurt-on-Main. Sept. 6, 1922.)

Electrolysis—Various products are obtained by the action of nascent oxygen or its equivalent, such as a halogen, produced at an anode having a very small active area compared with that of the cathode, current being supplied at such a pressure that the anode becomes hot, preferably incandescent. Substances to be treated are supplied to the electrolyte or introduced at the anode in dissolved or gaseous form. The substances may be fed through the tubular anode, of which only the end is exposed to the electrolyte. As shown, the anode 1 is surrounded, except at the ends, by a porcelain sheath 2. Instead of a single aperture, the anode may be provided with a number of small holes for the passage of the gas, etc., or may have a porous surface—for example, a coating of silver, platinum, osmium, iridium, carbon or graphite. Alternatively, the anode may be a solid rod, other means for introducing the reagents being provided. Platinum, graphite, lead, silicon and silicon alloys are suitable anode materials. The cathode may consist of the cell wall 4, of compressed carbon or other material and provided with flanges to which are bolted a base 5 and cover-plate 3, which may be of vulcanite, glass, asbestos, etc. A cylindrical diaphragm 7 of earthenware, fireclay, cement, asbestos, etc., extends from the cover nearly to the base, or in some cases into a groove in the base. An overflow 18 leads to a pump, which may return the electrolyte to the anode. Separate circulation of anode and cathode liquids may be provided for. Gases escape at atmospheric or reduced pressure. Under some circumstances intermittent heating of the anode may result from the alternate generation and absorption of gas. Oils from lignite, etc., may be oxidized to fatty acids by introduction through the anode, say in the form of an emulsion in concentrated solution of sodium bisulphate or bichromate, the electrolyte containing bisulphate with or without persulphates. Oil from Caucasian petroleum, emulsified with dilute sulphuric acid, may be treated in the presence of an electrolyte containing sulphuric and hydrochloric acids and sodium bisulphate or perchromates. Naphthene sulphuric acids and carboxylic acids are obtained. Oxygen may be supplied to the anode with the emulsion. If nitric acid is used instead of sulphuric acid, adipic acid is obtained. Substances resembling montan wax can be got by heating lignite under pressure with caustic alkali solution, mixing the product with sodium perchlorate solution and introducing the mixture into the electrolytic apparatus, which may be kept hot so that the wax can be run off in liquid form. Nitrates may be obtained by passing nitrogen-oxygen mixtures through multiple perforations of the anode into the electrolyte, containing a chloride or other salt of aluminum, magnesium, calcium or barium, with or without a salt of chromium, tungsten, or vanadium. Resin oils may be converted into resin acids. Methane may be oxidized to methyl alcohol, formaldehyde or formic acid, the electrolyte in this case, according to the provisional specification, being a concentrated solution of potassium permanganate containing 10 to 20 per cent of chloride of iron. Acetylene gives acetaldehyde and acetic acid. Hydrocarbons can be chlorinated, or nitro compounds obtained. (Br. Pat. 181,848. G. Plauson, Hamburg. Aug. 16, 1922.)



Tungsten Electrolysis—Tungsten or molybdenum trioxide or the corresponding hydrated oxide is reduced to a lower oxide in an electrolytic cell the cathode of which is immersed in a paste of the powdered oxide and an electrolyte such as dilute sulphuric acid in which the oxide is insoluble. A suitable composition for the paste is 900 grams of tungsten trioxide to 150 c.c. of dilute sulphuric acid of specific gravity 1.2. The paste may be contained in a porous pot, and may be agitated by a metal ring connected by spokes to a central rod. The cathode consists of about thirty thin rods of nickel-chromium alloy connected at the top to a metal plate through which the agitator rod passes. The anode may be of lead and may be inclosed in a porous pot containing scrap molybdenum which is oxidized during the process. The cathode paste may contain zinc sulphate or other soluble salt of a metal more oxidizable than tungsten or molybdenum. A current of 30 amp. at 6 volts, rising to 7 volts during the process, may be used, the current density being 0.10 amp. per sq.cm. at the cathode and 0.28 amp. per sq.cm. at the anode. The temperature is maintained between 40 and 60 deg. C. The reduced paste is washed to recover the acid and to remove impurities and then dried on a vacuum filter. The powder obtained may be reduced to metal by heating in a current of hydrogen, the product being obtained in a finely divided state; it may then be pressed into rods or bars and sintered. (Br. Pat. 181,837. R. E. Pearson and E. N. Craig, Hanwell. Aug. 16, 1922.)

Casein—Casein is prepared for use as a plastic material by dissolving it in a solution of sodium or potassium carbonate, sodium silicate, borax or ammonia, adding coloring matter to the solution if desired, and precipitating the casein with the reagent described below. The precipitate is worked up by heat into the desired forms and hardened with formaldehyde. The precipitating agent is made by dissolving zinc sulphite, potassium or sodium meta-bisulphite, glacial acetic acid and alcohol in water, adding zinc cuttings, decanting the clear liquor, treating this with milk of lime and filtering. (Br. Pat. 183,972. R. H. Abrey, London. Sept. 27, 1922.)

Benzanthrone Derivatives — An hydroxybenzanthrone is obtained by heating benzanthrone under pressure with caustic alkali solution in the presence of anthraquinone, with or without addition of a chlorate or nitrate. An aminobenzanthrone is obtained by heating the hydroxy compound with strong ammonia under pressure. (Br. Pat. 183,351. British Dyestuffs Corp., Ltd. Sept. 13, 1922.)

Coal Commission Faces Broad Problems

Lack of Coal Specialists Delays Completion of Staff

As the President's Coal Commission draws nearer to the mountain of work which it has been assigned to do, the commissioners are receiving a new impression of the enormity of the task and the very short time at their disposal. At a time when every hour is precious, they are experiencing exasperating delay in obtaining the technicians for their staff. It has become very evident during the past week that there is no surplus of coal specialists in the country. As a result, the commission is being forced to attempt to draft some of the trained men in the employ of the interests concerned. Due to the limited time and the large amount of work to be done a comparatively large staff of trained men must be put to work. There is a feeling that mine operators, the United Mine Workers, the exporters and the large consumers of coal should be willing to contribute to the success of the commission's work by being willing to make some sacrifice in the way of releasing specially qualified members of their own staffs.

Scope of Investigation

An idea of the task that is facing the members of the commission may be obtained from some of the alternatives between which they must choose. One of the most important questions the commissioners will have to consider is whether or not they will recommend amendments to the anti-trust statute which will authorize consolidations and permit of a scheme of collective marketing.

While it is possible that the commissioners may avoid a flat recommendation as to the rates of wage which they may regard as fair, it is certain that they must go deeply into the wage and living cost questions. In their report they will be expected to discuss and express opinions on such questions as a minimum wage, a guarantee of employment, and unemployment insurance.

It is not unreasonable to suppose that they will consider the place of trade unions in the business of coal production, especially when the organization of coal miners exerts such an important influence on the production of two-thirds of all the coal produced in the United States, which is incidentally nearly half the world's output. The commission is called upon to probe deeply into the affairs of the strongest labor union in the world.

While nationalization is specified as one of the points on which the commission must report, it is regarded as probable that it will be dismissed without extended discussion, although it is probable that the commission will see in the cry for nationalization a reflection of the course which the public instinctively pursues when called upon to pay unusual prices as a result of manipulations for which it is in nowise responsible.

Another big question with which the commission must wrestle is that of regulation. The commission will be expected to express its opinion as to whether or not coal falls into a public utility category.

Need of Feldspar Association Recognized

As the result of a preliminary conference and sounding of sentiment, a meeting of feldspar producers and grinders will be called to be held at the same time and place as the annual convention of the United States Potters' Association to form an organization for general handling of mutual problems and advancement of the industry. It is probable that the meeting will be held in Washington in December.

Standardization is an outstanding problem in the feldspar industry, it is pointed out, as at present there are wide variations of grades nominally identical. It is believed that an agreement on this point can be worked out satisfactorily only through an association, co-operating as a unit with the consumers.

Those interested in the organization of a feldspar association also declare that proper co-operation would bring about a wider market by a close study of the amount of quartz which may be left in the prepared product without injury and by means of interchanging soda feldspar and potash feldspar. It also is felt that by organized effort a wider field of usefulness for the product, which now is consumed principally in pottery and enameled ware, could be found.

The more important producers and grinders of feldspar in the United States number at least seventy. The principal production is along the Atlantic coastline, from Maine to Georgia, with some production in California and a little in Colorado.

Bureau of Mines and A.E.S. Co-operate on Research

At the recent meeting of the American Electrochemical Society in Montreal an advisory committee was appointed to consult with the Bureau of Mines on its electrometallurgical research work and to recommend to the bureau lines of research and investigation. The membership of the committee is made up of the following, who are also members of the Electrothermic Division of the American Electrochemical Society: Robert Turnbull, chairman; J. A. Seede, Dorsey A. Lyon, F. W. Brooke, E. L. Crosby, Acheson Smith, Colin G. Fink and C. A. Schluederberg.

The bureau will send monthly progress reports of its electrometallurgical work to the members of this committee. Among the suggestions for research work which the committee has already made to Dorsey A. Lyon, chief metallurgist of the Bureau of Mines, are: Specific heats at different temperatures; refractories; expanding of refractories; and spalling of refractories.

Joint Meeting of Ceramic Societies Scheduled for December

The New Jersey Clay Workers' Association and Eastern Section of the American Ceramic Society will hold an annual convention in the assembly room of the new Ceramics Building, Rutgers College, New Brunswick, on Dec. 12, with morning and afternoon sessions. An interesting program of technical and practical papers is being arranged. A committee has been appointed to perfect details of the gathering, composed of Prof. George H. Brown, director of the department of ceramics at Rutgers College; Abel Hansen, Fords Porcelain Works; LeRoy H. Minton, General Ceramics Co.; Leslie Brown, Lenox, Inc.; Frank R. Valentine, M. D. Valentine & Brother Co.; and George Simcoe, Perth Amboy Tile Works.

American Electrochemical Society Plans Spring Meeting in New York

For the first time in several years the American Electrochemical Society will hold its annual spring meeting in New York City, on May 3, 4 and 5, 1923. Very promising progress is being made on two symposiums: one on the production and application of the rare metals, under the direction of Dr. F. M. Becket, and the other on electrode potentials, under the direction of Dr. William G. Horsch. Headquarters will be at the Hotel Commodore.

More Tariff Jokers Come to Light

Customs Officials Straightening Tangles in Duties on Coal-Tar Products, Molasses and Paper Pulp

Some difficulty has been experienced in working out the provisions of the McCumber-Fordney tariff act dealing with the application of the United States value to coal-tar dyes and chemicals, which are given treatment different to that accorded to other classes of merchandise.

A joint conference among representatives of the Tariff Commission, the United States Bureau of Standards and the Customs Division of the Treasury Department was held in New York, Nov. 2 and 3. Plans were discussed for determining the standard strength of coal-tar dyes in commercial use prior to July 1, 1914, and gathering samples of domestic dyestuffs for comparative purposes for proper administration of the new tariff act.

Chemicals Cause Heavy Work

The conferees also discussed the needs of the laboratory at the appraiser's stores in New York, which is to be enlarged both in equipment and in personnel so as to be able to make the tests which will be required in assessing duties on coal-tar products. Announcement of the appointment of the chief of this dye-testing laboratory is expected to come from the Customs Division within a few weeks. It is planned to give him three assistant chemists and the necessary clerical force.

The chemical work thrown upon the Customs Division because of the two coal-tar products paragraphs of the new tariff bill is heavy. Domestic products must be determined, because the act provides that where there is a comparable domestic coal-tar product, the imported product shall be assessed for duty on the basis of the wholesale selling price of the American product. Non-competitive imports are to be assessed on the basis of United States value.

The basis of assessment also is to be upon the strength in commercial use prior to July 1, 1914. Prior to that date many dyes were imported in single strength which now come in in double, treble or even greater strength. The change in form of imports is particularly true of vat dyes. In the case of dyes coming in with higher strength than in the first half of 1914, the specific duty of 7 cents per pound will be increased proportionately. This will give a "concealed protection" to some domestic dyes not shared by others and is one of the inequalities of the new tariff act.

Molasses Practically Embargoed

An almost prohibitive duty will be assessed against imports of molasses if an interpretation said to have been made by the Treasury Department of the wording of the molasses provisions of the McCumber-Fordney tariff law holds. The intent of Congress apparently is not carried into the language of the provisions, and it is understood that the Treasury Department takes the stand that it has no alternative than to interpret literally Paragraph 502.

9½ Cents per Gallon on Blackstrap

The same situation is found to be present with respect to the latter part of this paragraph dealing with blackstrap molasses. Congress provided a rate of one-sixth of one cent per gallon when testing not above 52 per cent total sugars; testing above 52 and not more than 56 per cent total sugars, one-sixth of one cent additional for each per cent of total sugars and fractions of a per cent in proportion.

On this basis sugars totaling 56 per cent in molasses would take a rate of one-sixth cent per gallon up to 52 per cent, and then along will come the excess rate—56 times one-sixth cent per gallon plus one-sixth cent per gallon; so that the assessment will be 9½ cents per gallon.

Logs for Paper Pulp Erroneously Taxed

Another oddity of the McCumber-Fordney tariff act came to light following complaints to Washington from importers of logs that Collectors of Customs are seeking erroneously to collect duties when the logs are free of duty as pulp wood. Paragraph 1700 provides for the free entry of "wood: logs, timber, round, unmanufactured, hewn, sided or squared otherwise than by sawing; pulp woods. . . ."

The conflicting paragraph is Paragraph 401, "logs of fir, spruce, cedar, or Western hemlock, $1 per thousand feet board measure."

The importers protested to the customs officials at ports involved that this lumber is strictly for pulp wood production uses, and the Collectors are said to have held up the entries awaiting action in Washington as to the methods to be pursued in handling log imports. There is no doubt as to the intent of Congress to place pulp wood on the free list, so that construction is not involved.

Perkin Medal Awarded to M. C. Whitaker

The committee in charge of the annual award of the Perkin medal met last week at the Chemists' Club and selected Dr. M. C. Whitaker, vice-president and general manager of the U. S. Industrial Alcohol Co., as the recipient for 1923. The presentation will be made at a meeting of the American section of the Society of Chemical Industry, Jan. 12, 1923. The medal is awarded annually under the auspices of this organization, having been established in 1906 on the occasion of the visit to this country of Dr. William Henry Perkin of England. He was the first recipient of the medal, which has been awarded annually since that time for conspicuous contributions to the science and industry of chemistry.

Helium Legislation to Be Pushed

Federated American Engineering Societies Emphazises Importance of Early Hearings on Pending Bill

The desirability of conducting hearings at the earliest possible time on the bill providing for the conservation and production of helium has been emphasized in representations made by the Federated American Engineering Societies to the chairman of the Public Lands Committee of the House of Representatives. The legislation has the indorsement of the President and the members of the Cabinet concerned with helium production. The request of the Federated Engineering Societies was to the effect that these hearings begin during the extra session of Congress, should one be called, or if not, that they be undertaken immediately on the reassembling of Congress in December.

Kahn Bill Pending

It is well known that large quantities of helium are daily going to waste. Representative Julius Kahn, of California, has introduced a bill in Congress to support a definite program of helium recovery. This bill is in the hands of the Public Lands Committee. It has the indorsements of the President and Secretaries Denby, Weeks and Fall, and its purpose is to develop the best methods of recovering helium and to collect and store supplies for military and commercial uses. The recent disaster which met the attempted flight of the hydrogen-inflated dirigible C-2 at San Antonio, Tex., again emphasized the necessity for using a non-flammable gas in balloons.

Progress in Technology

Satisfactory operation on a laboratory scale of a simplified and much cheaper method of recovering helium is reported by the Bureau of Mines. In a test run made within the last month at the cryogenic laboratory in the Interior Department Building, helium was recovered from natural gas in one operation in sufficient purity for use in dirigibles or balloons.

Helium recovery as carried on at government plants in Texas results in a gas of about 64 per cent purity and necessitates a second operation to remove impurities. By the old method the flow from the natural gas wells is directed through a series of compressors which reduce the various gases in the mixture to liquid form. Methane becoming liquid at a higher temperature is taken off first. The remaining gases are then, one by one, liquefied, leaving helium, which has an exceedingly low liquefying point. The difficulty with the old method is to liquefy all the nitrogen.

It is planned to erect a semi-commercial plant and apply the new method to quantity production. The workers have hopes of being able to do in large scale operation nearly as well as they have done in the laboratory.

A.S.M.E. Plans Big Meeting in New York

Joint Sessions With Other Societies Will Attract Many Engineers

The annual meeting of the American Society of Mechanical Engineers, the biggest of the national engineering gatherings of 1922, will be held in the Engineering Societies Building, New York City, Dec. 4 to 7. At that time John L. Harrington of Kansas City will succeed Dean Dexter S. Kimball of Cornell as president of the society.

A feature of the meeting, which will attract engineers, manufacturers, economists, educators and industrialists from all over the country, will be joint sessions with the American Economic Association, the American Society of Safety Engineers, the American Society of Refrigerating Engineers and the American Engineering Standards Committee.

H. F. Loree, president of the Delaware & Hudson R.R. Co., and E. M. Herr, president of the Westinghouse Electric & Manufacturing Co., will be among the speakers at the economic forum, at which addresses also will be delivered by Dr. W. C. Mitchell of the National Bureau of Economic Research, professor of economics at Columbia University; Prof. H. R. Seager of Columbia, president of the American Economic Association, and Dean Kimball. Mr. Herr's topic will be "The Human Problem in Industry." Professor Mitchell will discuss "Making Money and Making Good."

Subjects for Discussion

The sessions of the professional divisions of the society will cover a wide range of industrial and technical progress, including development in aëronautics. Orville H. Wright is a member of the aëronautics division. Other professional divisions to meet include those devoted to fuel, management, forest products, ordnance, railroads, textiles, gas power, machine shop practice and materials handling. The ordnance division is working with the army authorities to produce better ordnance and eliminate the evils revealed by the war.

Education, described as a question of increasing interest in the engineering profession, will be one of the big features of the meeting, to which representatives from practically all the leading universities and technical schools will come. Notable among the reports to be presented will be that by the committee on training for the industries, covering recent advances in correspondence work in extension schools, industrial training schools, and training in the works.

Student Sections Meet

The American Society of Mechanical Engineers maintains student branches in sixty-two colleges and technical schools, and in connection with the meeting a session planned and directed by students themselves will be held. Research will be a principal topic and several papers telling of its progress will be read. Local sections and branches of the society from fifty-four industrial centers will send delegates to the meeting. Activities of the professional divisions represent 8,970 members. A special program in which women are taking an active part is being arranged.

Other features of the meeting will be public hearings on the society's boiler code, which has formed the basis for laws in eighteen states, and on the power test code; local sections conferences, presidential address and reception, and a business meeting. The opening event will be a meeting of the society's council on Monday, Dec. 4.

New Committee Chairmen

Elections of executive committees to direct the work of the professional divisions during the coming year are announced at the national headquarters of the society in New York. The new chairmen are:

Aëronautic Division, Major Thurman H. Bane, U. S. Air Service, Dayton, Ohio; Forest Products Division, Thomas D. Perry, Grand Rapids, Mich.; Fuels Division, Prof. L. P. Breckenridge, Yale University; Gas Power Division, Van H. Manning, director of technical research, American Petroleum Institute, New York; Machine Shop Division, F. O. Hoagland, Worcester, Mass.; Management Division, R. A. Wentworth, Long Island City, N. Y., Materials Handling, H. V. Coes, Philadelphia, Pa.; Ordnance, Waldo H. Marshall, New York City; Power, John H. Lawrence, New York City; Railroad Division, James Partington, New York City, and Textile Division, Charles T. Plunkett, Adams, Mass.

Delegates to the American Engineering Council have been elected by the society as follows: L. P. Alford, New York City; E. R. Fish, St. Louis; Dean Arthur M. Greene, Princeton; John L. Harrington, Kansas City; Edwin B. Katts, New York City; Fred R. Low, New York City; Fred J. Miller, New York City; S. W. Stratton, new president of the Massachusetts Institute of Technology; and Max Toltz of St. Paul.

Government to Study Recovery of Byproducts From Wool Scouring

With legislation in prospect dealing with the pollution of streams, a more active interest is being manifested in utilizing the byproducts of wool cleaning. The problem is being worked on actively at the Bureau of Chemistry in the hope that means may be found which will make it possible to recover the grease and potash in cheaper and more effective methods than have been tried heretofore.

The Bureau of Chemistry recently made an exhaustive survey of the subject and finds that the average grease content of wool is 15 per cent and that the average potash (K_2O) content is 4 per cent. In some instances the grease content ran as high as 35 per cent and the potash content as high as 6 per cent.

Phosphate Rock Prospects Are Good

Fertilizer Companies Expect Big Year—Hydro-Electric Power Needeed

Development of the potential hydro-electric power of the Duck River, which runs through the northern portion of the phosphate rock fields of middle Tennessee, or the Buffalo, which runs a few miles to the west of the deposits, has been suggested by men in the phosphate rock business in that section. It is thought that the greatest need of these fields at the present time is cheap hydro-electric power. It had been hoped by these interests that the work at Muscle Shoals would be rushed to such an extent that they could get power from that source. They are now looking around, however, for another source for this power.

The phosphate rock mining, crushing and washing in this section have grown to large proportions during the past 2 years, in spite of the small comparative sale of fertilizer during that period. At present 600,000 tons per year are mined and employment is given to 2,000 men.

Most of the rock being mined at present is being shipped to the Northwest for the wheat crops. As soon as these shipments are completed the rock will be diverted to the plants of the various fertilizer companies in the South, to be used in the production of complete fertilizer for next year's crops. It is predicted that fertilizer sales will take a big lead over those of the past 2 or 3 years. This is accredited to the fact that very little fertilizer has been used in the past 2 or 3 years by the Southern cotton farmer, and with the demand for cotton being ahead of this year's crop, the farmers will be encouraged to try to produce larger crops next year.

Recent announcement has been made that the American Agricultural Chemical Co. will erect a large crushing and washing plant in connection with a large tract of proved, high-content rock which it holds near Cleburne, Tenn. Work on this plant is progressing and it is thought that it will be started into operation in time to produce rock for next spring's fertilizer business.

Complaint Lodged Against Varnish Company

The Federal Trade Commission alleges methods of unfair competition in a complaint issued against the Don-O-Lac Co., Inc., of Rochester, N. Y.

The concern is a manufacturer and distributor of paints, varnishes, shellacs and kindred products, and is charged in the complaint with advertising and selling under the name of "American Shellac" a substitute for shellac which is inferior to shellac as commercially known. The trade and the general purchasing public, the complaint avers, is thereby deceived into the belief that the product is composed of shellac gum and alcohol, when such is not the case.

Water-Power Act to Be Defended

Committee Formed to Support Its Provisions, Which Would be Violated by Ford Muscle Shoals Proposal

Declaring that the principles of the federal water-power act passed in 1920 after 15 years of discussion in Congress and of effort by the friends of conservation are under attack from divers quarters and that the law itself is in danger, Philip P. Wells, formerly chief law officer of the U. S. Forest Service and later of the U. S. Reclamation Service, has announced that a national committee for the defense of the act has been formed.

The State of New York has brought suit in the Supreme Court of the United States to have the water-power act annulled. The Federal Power Commission, administrator of the act, is, by a decision of the Comptroller of the Treasury, forbidden to spend the money appropriated by Congress for the employment of experts urgently needed for the proper administration of the act. Congress does not take up the very simple legislation necessary to cure this defect, but has given a vast amount of time to Henry Ford's proposal at Muscle Shoals, which violates every one of the principles of the act and gives to Mr. Ford, in addition, a vast subsidy from the federal Treasury.

Ford Terms a Bad Precedent

If this proposal were accepted by Congress, every corporation which has or desires a water-power privilege would demand a lease on Mr. Ford's terms. And how could they be denied? The acceptance of his offer would be a deadly blow to the application of the principles of conservation to the use of water power.

The water-power act of 1920 embodies those principles, and thereby protects the public interest in obtaining full development without having to pay monopoly profits. It does this by requiring:

(1) That every water-power lease shall be limited to a maximum of 50 years.

(2) That the lessee shall pay the government a small rental for the power privilege when he builds his own dam and other works, and a larger and fair rental when he uses works constructed by the government.

(3) That the lessee must submit to regulation by state authority, or, if there is no state authority, by the Federal Power Commission, of the services he renders and the prices he charges for light and power.

(4) That any excess profits over a fair liberal return on the actual investment shall be made over to the public in the form of a reduced price for the lessee's works at the end of his 50-year term.

(5) That states and cities have first call on power sites.

None of these requirements would be imposed under the Ford offer, acceptance of which by Congress would therefore be practically tantamount to a repudiation of the federal water-power act. That act is at once progressive and practical. It safeguards for all time public rights in the greatest of natural resources, but it is acceptable to investors in and to managers and promoters of water-power enterprises today. It was framed with great care and embodies, perhaps beyond any other law on the statute books, the conclusions of experts in engineering, economics, legislative drafting and constitutional law.

Committee Members

Among the members of the committee which will stand for the support of the act are James R. Garfield of Cleveland, Walter L. Fisher of Chicago and John Barton Payne of Chicago, former Secretaries of the Interior; Henry L. Stimson of New York, Lindley M. Garrison of New York and Newton D. Baker of Cleveland, former Secretaries of War; David F. Houston of New York and Edwin T. Meredith of Des Moines, former Secretaries of Agriculture; Governors Henry J. Allen of Kansas, Joseph M. Dixon of Montana and John M. Parker of Louisiana; Gifford Pinchot, Republican candidate for Governor of Pennsylvania; Henry S. Graves, head of the Yale Forestry School, until recently chief of the U. S. Forest Service; Herbert Knox Smith of Connecticut, former Commissioner of Corporations; William Kent of California, former Congressman, and other prominent conservationists.

Ferro-Alloy Duty to Be Based on Buyers' Analysis

Explaining that commercial sampling of ores and alloys used in the manufacture of steel is an elaborate and expensive process for which the Customs Division has no facilities, the Treasury Department has notified Collectors of Customs to use the determinations made for settlements between buyers and sellers as the basis for collecting final duties on such imports. Collectors are instructed to preserve samples for a checking analysis against the figures of buyer and seller.

The instructions further assert that inasmuch as most of the imported manganese ores contain from 45 to 55 per cent metallic manganese, Collectors are authorized to accept estimated duties on the basis of an average of 50 per cent metallic content.

This ruling disposes of one of the features of the new tariff act which has caused administrative officials much study. The duties on ores and alloys used in steel manufacture are based on the metallic content. Investigation disclosed that accurate sampling would be too expensive for the Customs Division to undertake independently and the decision to accept the settlements between buyer and seller as the basis for assessing duties followed.

German Beet Sugar Industry Fatally Crippled

Germany will never again be able to export 1,000,000 tons of sugar, as it did before the war, according to Alfred P. Dennis, special representative of the Department of Commerce in Europe. Perhaps 10 years from now it may have a surplus of 500,000 tons, but for the immediate future it will have all it can do to supply domestic needs.

Germany for years has been the leading beet-sugar producer of the world. Second place in world production, formerly occupied by Russia, has now been taken by the United States. With production cut approximately in half by the war, the recovery of the German sugar industry is a matter of practical concern to American beet growers and sugar refiners.

For the past seven years Germany has been entirely out of the sugar export trade, and during the last season was under the necessity of importing 150,000 tons or more to cover absolute domestic requirements.

Loss of Beet Lands

Within the territory turned over to Poland by Germany under the terms of the peace settlement were 296,400 acres of beet-sugar land. Indeed, some of the best beet-sugar soil of the old empire was in the Posen region and the so-called Danzig corridor. With the territory there passed also to Polish control two sugar refineries and upward of 30 sugar factories. Experts estimate that 450,000 tons of sugar production has been lost to Germany by territorial cession out of the 2,700,000 tons of pre-war sugar capacity.

Aside from territorial losses, beet growing has been further curtailed in the area now included in Germany, the acreage having fallen in the post-war period about 21 per cent, while yields per acre have fallen off approximately 30 per cent. The two main factors that check rising production are labor difficulties and soil deteriorations.

The deterioration of the German beet-growing soil is connected with reduced imports of oil-cake and phosphatic fertilizers. Experts agree that it will take at least 10 years for the German sugar industry to get back to its pre-war position.

Cuban Sugar Mill Breaks Production Record

Establishing a world record, a Cuban sugar mill has already ground over 350,000,000 pounds of sugar this year to August 31, according to a report received by the Department of Commerce. Indications are that the crop which will soon be finished will amount close to 4,000,000 long tons. During the first eight months of 1922, 1,473,064,829 pounds of sugar valued at $35,059,803 were shipped from Cuba to the United States—about twice the quantity shipped during the same period of 1920 when sugar prices were excessively high. The 1920 sugar was valued at $88,374,248.

Manufacturers to Standardize Fertilizers

Confer With Experiment Station Officials in Chicago on Methods of Reducing Varieties of Product

Reduction of the number of mixed fertilizer analyses for use in Ohio, Indiana, Michigan, Missouri and Wisconsin from the fifty or sixty now marketed to fifteen, involving elimination of low grades, fractional analyses and poorly balanced mixtures, was agreed upon at a conference among agronomists of the five states and representatives of nineteen fertilizer manufacturers doing business in the Middle West, together with representatives of the soil improvement committee of the National Fertilizer Association.

It is expected that this agreement will prove the forerunner of similar action for other groups of states, with resultant benefit to the farmers, by simplifying selection of the proper analyses for certain soil and crop conditions and to the manufacturers by reducing the number of analyses manufactured.

For several years meetings have been held in various states where manufacturers of fertilizer were brought into touch with officials of the experiment stations. These are to be continued.

MANUFACTURERS APPRECIATE RESEARCH

Manufacturers' representatives at the Chicago conference adopted resolutions to direct their sales policy to encourage the sale of the mixed fertilizer analyses recommended by the agronomists above others. The manufacturers also favor state meetings of their traveling salesmen, when they may receive information of experimental work with fertilizers. Another resolution approved the desire expressed by certain state experiment station and control officials to have determined and published the availability of the nitrogen in fertilizers and recommended that reports of availability be expressed as percentages of the total nitrogen present.

State agronomists at the conference were Prof. Firman E. Bear, Ohio State University; Prof. A. T. Wianoko, Purdue University; Prof. M. F. Miller, University of Missouri; Prof. A. R. Whitson, University of Wisconsin, and Prof. M. M. McCool, Michigan Agricultural College.

The fertilizer manufacturers represented were: Alliance Fertilizer Co., American Agricultural Chemical Co., Armour Fertilizer Works, Calumet Fertilizer Co., Darling & Co., Diamond Fertilizer Co., Farmers Fertilizer Co., Federal Fertilizer Co., Groves Fertilizer Works, Hopkins Fertilizer Co., International Agricultural Corporation, Jarecki Chemical Co., Morris & Co., F. S. Roster Guano Co., Smith Agricultural Chemical Co., Swift & Co., Virginia-Carolina Chemical Co., Welch Chemical Co. and Wuichet Fertilizer Co.

SEE MUTUAL ADVANTAGE

Returning from Chicago, where the conference was held, Prof. William D. Hurd, director of the soil improvement committee, predicted mutually beneficial results from the agreement. "The conference was marked by a splendid spirit on the part of both the state officials and representatives of the industry," said Professor Hurd. "The subjects involved were approached with an appreciation of one another's viewpoint and there was much frank and wholesome discussion.

"The state agronomists will now formulate their recommendations for various soils and for best crop conditions, based on the selected analyses. Instead of a multiplicity of recommendations, which are confusing and irritating to the farmer, there will be an unanimity which cannot but increase fertilizer usage, to the benefit of farmer and manufacturer alike."

Fish Oil Factory for British Columbia

The Ferphos Fish Products, Ltd., has been organized at Victoria, B. C., for the purpose of taking over the patents of E. G. Henshall and of building and operating a factory at Skidegate Inlet, Queen Charlotte Island, for the manufacture of oil and fishmeal from dogfish, which abound in the Northern Pacific waters.

For some time past Mr. Henshall has been operating a small experimental plant at Sooke, 20 miles from Victoria, and claims to have demonstrated that, by his process, the whole of the fish can be used and 100 per cent more oil be extracted than by methods hitherto used, and that a better grade of oil is obtained. By the old method oil was extracted only from the liver of the fish and, except in a few instances where the fish was used for fertilizing nearby land, the rest of the fish was wasted. By the old method 50 tons of fish yielded 100 gal. of oil, which sold on an average at 40 cents per gallon, whereas by the Henshall process the same quantity of fish is said to yield 200 gal. of oil and 2,000 lb. of fishmeal, the total value of which is more than $150. Local paint manufacturers have taken all the oil produced at the experimental plant and have pronounced it high grade. The Provincial poultry inspector has indorsed the fishmeal as a suitable food for poultry. The plant at Skidegate Inlet will have a capacity of 50 tons of dogfish per day, and will be thoroughly up to date in every way. The dogfish found in the waters near the inlet range from 10 to 40 lb. in weight.

Propose Fertilizer Payment to German Grain Farmers

According to the official Prussian press service the Prussian Government has proposed to the Reichsrat to pay the farmers the increase in the price of grain quotas in the form of Chilean saltpeter. According to the proposal the 1923 harvest would show an increase of 3 to 4 million tons of grain. Only in this way, says the preamble of the Prussian proposal, can a cheapening of the price of bread in the near future be effected.

Personnel Association to Meet in Pittsburgh

Industrialists, educators and personnel experts representing the country's largest business and manufacturing enterprises will engage in a 3-day national forum, beginning Nov. 8, at Pittsburgh under the auspices of the National Personnel Association. Centering around the numerous discussions, addresses and committee reports, covering a wide range of administrative effort, will be the problem of "the human factor," now of outstanding importance in this and other countries.

The Pittsburgh gathering will mark the first annual convention of the National Personnel Association, which has taken over the activities of the National Association of Corporation Training and the Industrial Relations Association of America. Immigration, psychological tests, motion pictures, pension plans for workers, employment and labor turnover, shop training and the relation of industry to both the engineering and the public schools will be discussed as questions pressing for solution.

The announced purpose of the convention is "to advance the understanding of the principles, policies and methods of creating and maintaining satisfactory human relations within commerce and industry."

NOTED SPEAKERS

Michael Pupin, professor of electromechanics at Columbia University and famous as an inventor for his contributions to the wireless art, will deliver an address on "The Immigrant's Point of View." Professor Pupin, born in Serbia, began life as a shepherd boy, coming to America with a nickel and an apple as his sole possessions. Magnus W. Alexander, managing director of the National Industrial Conference Board, will speak on "Our Immigration Policy and Its Social and Economic Effects." George F. Quimby, industrial service secretary of the Associate Industries of Massachusetts, will discuss "Training Immigrant Workers."

Other speakers will be H. M. Jefferson, Rowland Rogers and Dr. Lee Galloway of New York, Oscar M. Miller, Bayonne, N. J.; Cator Woolford, Atlanta, Ga.; J. W. Dietz, New York; Martin W. Dodge, New York; Harry A. Hopf, New York. Major W. A. Magee of Pittsburgh will address the delegates, for whom social events have been arranged by the Pittsburgh Personnel Association.

Chamber Sulphuric Acid Plant to Be Built for City of Buenos Aires

Considerable interest in heavy chemical circles has been focused on developments in South America during the past year. It is now announced that a contract for a large chamber sulphuric acid plant to be erected by the City of Buenos Aires, Argentina, has been awarded to the Chemical Construction Co., of Charlotte, N. C.

Manufactured Gas Sales Increase Greatly

Growing Use in Industry and New Domestic Appliances Explain Growth

Sales of manufactured gas for 1921 touched a new high figure of 326 billion cubic feet, an increase of 7 billion cubic feet over 1920 and 20 billion cubic feet over 1919, according to the third annual survey of the gas utilities of the United States just completed by the American Gas Association.

Coincident with the compilation of its 1921 figures, the association has also made an analysis of the per capita consumption of gas for the last twenty years. This shows that the per capita increase for the ten-year period 1901 to 1911 was 30 per cent, while for the period 1911 to 1921 it was 80 per cent, showing that the American people during the last ten years consumed nearly three times as much gas per capita as they did during the preceding decade.

One of the principal factors in this increase is said by the association to be due to the growing use of gas in industrial plants during the last ten years. At the present time, the survey shows, about 22 per cent of the total amount of gas sold is used by industry.

Figures showing the domestic use of gas also reveal a remarkable increase. At the end of 1921, according to the association, 46,700,000 persons in the United States were served with gas through 69,500 miles of mains and 9,291,000 meters, the gas being used in 7,040,000 cooking appliances, 1,573,000 water heaters, 1,268,000 space heaters and 8,800,000 incandescent burners. This is an increase over 1920 of 363,000 customers, 314,000 meters, 1,000 miles of gas mains, 370,000 cooking appliances, 150,000 water heaters, and 144,000 space heaters.

Of the total amount of gas sold for the year 1921, 18.50 per cent was for illumination, 56.71 per cent for domestic uses other than illumination, 21.62 for industrial uses and 3.17 for other uses not classified.

Miniature Working Models Will Feature Power Exposition

Among the interesting features which will be displayed at the National Exposition of Power and Mechanical Engineering, at the Grand Central Palace, New York, during the week Dec. 7 to 13, are several elaborate models of modern installations.

As an excellent example of the manner of preparing anthracite coal for the market, the model of the famous Loree breaker of the Hudson Coal Co. will be exhibited. This model, requiring an entire express car for shipment to the exposition, is a replica of the largest breaker in the world, which was erected and put in operation in 130 days and in 1921 handled 591,000,000 tons of coal. This model will show the breaker in operation, crushing the large lumps of coal, sizing it through screens and passing the sized coal through jigs, where the refuse material is separated.

The development of the power station will be illustrated by the exhibition of a series of models of the important central stations in New York City. The original station erected by Thomas Edison in Pearl Street will appear beside the more modern Waterside stations and the recent Hell Gate station. The representation of this latter station is a faithful reproduction built to a scale of one-quarter of an inch to the foot. It shows the steam and electric apparatus in the plant and the various boiler room and turbine room auxiliaries as well as the elaborate machinery for handling the enormous tonnage of coal and ashes.

Rubber Paving Block Is Developed in England

Composition Core With Vulcanized Cover May Be Commercially Practical

A new type of rubber composition paving block has been produced by Wingate & Sutton, 5 Victoria St., Westminster, London, according to a report to the Department of Commerce by Consul Coulter, London, which, it is claimed by the manufacturers, can be placed on the market at a price to compete with the ordinary creosoted wooden block, when the advantages of absence from noise and long life, estimated at 15 years, are taken into consideration.

Two types of blocks have been produced, a No. 1 block, made of the "core" surfaced with a half-inch hard vulcanized rubber, and a No. 2 block, which consists of the "core" only. The principal ingredients of the core, which has been patented, are rubber, jute and china clay. These ingredients enable the whole block to be vulcanized in one piece, and it has been found by experiment that the block should be a solid mass and not made up of separate superimposed portions.

In an experiment of a wooden block upon which a steel plate was placed as a seat for a rubber surface, it was found that the heavy traffic turned up the steel plates at the edges. At St. Pancras Railway station the covered way under the hotel is covered with a sheet of rubber of about ½ in. thickness. It has been found, it is claimed, that there is a tendency for the rubber sheet to "lick up" so that it must be pegged down from time to time. As a result of various experiments, Wingate & Sutton have decided that the separate solid block gives the best results. The block proposed is similar to the wooden block used ordinarily for street paving, and measures 9x4½x3 inches.

Up to the present time it has not been possible to manufacture rubber blocks at under three times the cost of wood paving which is about $5.40 per square yard. The Gould block core it is claimed can be made at about 4 cents per pound and it is hoped that the price of paving will not be more than $13.35 per superficial square yard.

Personal

FREDERICK FRANZ, who for the past 4 years was chief engineer of the Terminal Engineering Co., has opened an engineering office at 27 Warren St., New York City. He will devote attention particularly to labor-saving machinery for industrial plants.

H. A. GARDNER, of Washington, D. C., gave an address on the technology of paints before the members of the Lehigh Valley Section of the American Chemical Society, Allentown, Pa., on Oct. 20.

ALEXANDER LEGGAT, formerly a consulting engineer at Butte, Mont., and previously connected with the engineering department of the Anaconda Copper Mining Co., has been appointed manager at the plant of the Richmond Mining, Milling & Reduction Co., Wallace, Idaho. Mr. Leggat is a graduate of the Houghton, Mich., School of Mines.

Prof. W. A. NOYES of the University of Illinois has been granted a year's leave of absence for study and research in Europe.

Dr. WALTER ROSENHAIN, of the National Physical Laboratory of Great Britain, will deliver the second annual lecture of the Institute of Metals Division of the American Institute of Mining and Metallurgical Engineers. The subject will be some theoretical phase of non-ferrous metallurgy. During his visit in this country Dr. Rosenhain will deliver lectures at Massachusetts Institute of Technology, Yale, Columbia, Case School of Applied Science and Franklin Institute.

Dr. C. G. SCHLUEDERBERG, of the Westinghouse Electric & Manufacturing Co., expects to sail for the Orient late in November and will be away several months. He is president of the American Electrochemical Society.

C. E. SKINNER, assistant director of engineering of the Westinghouse Electric & Manufacturing Co., has sailed to attend the meeting of the rating committee of the International Electro-Technical Commission to be held in Geneva, Switzerland, beginning Nov. 18. Mr. Skinner organized and directed the research work of the Westinghouse company until his recent promotion to the position of assistant director of engineering. The chief work to be taken up by the committee at Geneva will be to obtain final agreement on the basis of rating of all classes of electrical machinery.

Dr. M. C. WHITAKER, vice-president and general manager of the U. S. Industrial Alcohol Co., New York, has been selected as the recipient of the Perkin medal to be presented Jan. 12, 1923.

WALTER G. WILLARD, field secretary of the Western Petroleum Refiners' Association, resigned Nov. 1.

Market Conditions

In Chemical, Metallurgical and Allied Industries

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities Prevailing Prices and Market Letters From Principal Industrial Centers

Inflation!

What Is It? Is It Coming? How Shall We Know When It's Here?

"How's business?" we asked a chemical manufacturer.

"Good," he replied, "I'd say fine, if I dared, but 1920 isn't so many years ago, and I said fine then."

"I suppose you're afraid of overproducing again?" we queried.

"Man, I'm more than afraid of it. I have cold shivers every time I think of 1920. We are buying from hand to mouth and it will be some time before we change."

That's the principal reason why we don't need to worry about inflation for a while. Very few manufacturers will forget 1920 and 1921 for a while and conservative business policy will probably rule for some time. So we have answered the second question before we have answered the first. Calamity howlers and rising prices in a few lines do not indicate inflation any more than a gray cloud in July indicates snow.

Modifying Conditions to Evaluate in Studying Inflation

Increasing prices, advancing wages and increasing loans by banks are all indications of an inflation. But these must be studied in the light of modifying conditions. At the present time we have all of these things, but increasing prices are due to the shortage and high price of coal as a result of the strike and to higher wages. Higher wages are largely attributable to more emigration and less immigration. The increase in bank loans is due to a resumption of business activity and the fact that banks are beginning to look for commercial loans. During the past year over one and a half billion dollars worth of securities have been acquired by banks. Quite an appreciable part of these securities has been due to the floating of bond issues by corporations which came out of the boom and depression cycle with heavy bank indebtedness. Although the banks have largely absorbed these securities, they are now ready to market them to customers, and this they could not do with loans. So we have a condition wherein Barkis is willing (meaning the banks) to make commercial loans and they are able to do so to a greater extent than ever before, since the reserve requirements under the federal reserve act are less and the confidence in the reserve system is established.

But don't forget that Barkis himself had pretty hard sledding and he isn't going to dash into commercial loans with the old 1920 abandon—not for some years, even if it is tempting and a customer or two may be lost by more liberal credit grants by competitive banks.

Inflation Signals—How to Recognize Them

Where inflation begins is an uncertain point. There will undoubtedly be an inflation-deflation cycle in many industries before a period of general inflation lures us again to believe that "permanent" prosperity is ours. It therefore behooves us to learn the inflation symptoms in individual industries as well as in the country in general. Such symptoms are not easily discernible and not always reliable. One danger signal is when material sold exceeds normal consumption without apparent reason. That often means larger stocks laid in, anticipating larger demand, but if the normal consumption is exceeded, inevitably there will follow a reaction. A rise in price eliminating, if possible, speculative causes may be another danger signal. Wage increases within an industry and large increases in productive capacity are other signposts. But none of them are certain.

A Word of Caution

A word of caution to the technical man is not out of order. Everyone knows how much easier it is to operate with large stocks of raw materials available and with a stockroom crammed with every conceivable item which might be needed. Therefore the pressure of the operating man is always to increase stocks of all kinds. They should remember that there is another side to the question and that perhaps there is valid reason for scaling down orders — a thing which invariably arouses ire in the plant. The reason is a desire to avoid inflation.

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	157.01
Last week	157.77
November, 1921	146.82
November, 1920	240
April, 1918 (high)	286
April, 1921 (low)	140

An error in the weighted index number for last week necessitate the publishing of the correct index number and for sake of clearness we are also publishing the figures for the two weeks previous.

October 18, 1922	153.77
October 25, 1922	157.71
November 1, 1922	157.77

Department of Commerce Items

Two rather striking items received attention in the recent *Commerce Reports*. One was newsprint paper and the other was steel.

Export Steel Trade Declines

The absence of expected purchases by Japanese interests has caused a loss in the August export figure for iron and steel. The monthly export figure showed steady improvement through the winter and reached a maximum in May. June showed a slight decline, but was still slightly in excess of 200,000 tons. The July and August figures represent only about 75 per cent of this figure, however, and unless an improvement takes place the yearly total will hardly equal the estimated figure of 2,200,000 tons.

While we are on steel and iron the situation in Germany is interesting. The exports are still slightly ahead of imports, but only slightly, and the expectation is that the year will show an unfavorable balance. The following figures are of considerable interest indicating the nature of the exports and imports in the iron and steel industry in Germany. The figures are for the first 7 months of 1922 and are recorded in tons:

GERMAN EXPORTS AND IMPORTS OF IRON AND STEEL FOR THE FIRST 7 MONTHS OF 1922

	Exports	Imports
Pig iron, scrap and ferro-alloys	116,806	507,437
Ingots, blooms, slabs, billets and sheet bars	27,541	144,821
Rails and accessories	206,266	61,412
Bar iron, hoop and girders	290,856	351,217
Rolls	4,779	108
Plates and sheets	137,969	33,003
Tin plate, galvanized sheets (plain and corrugated) and other sheets	16,900	7,473
Cast-iron pipe	26,935	25,871
Tubes and fittings	81,607	5,730
Bridge and other structural work	33,759	1,061
Railway axles and wheels, tires and springs	33,015	70
Carriage and cart axles	1,950	126
Wire, rolled and drawn	89,160	27,923
Wire rope and cord, barbed wire, wire gauze and cloth	36,116	261
Wire and cut nails and tacks	35,003	114
Screws and rivets	17,374	3,679
Ships' anchors	138	1
Horseshoes, calks, horseshoe nails and nails n.e.s.	2,914	21
Chains	4,390	38
Cask buoys, tanks, containers	6,613	220
Wagon springs	876	266
Iron and malleable castings and forgings, including machine parts	24,047	7,990
Total	1,195,014	1,178,842

Newsprint Paper

A table is given herewith of the estimated annual producing capacity and consumption of newsprint.

Perhaps the most interesting single

ANNUAL PRODUCING CAPACITY AND CONSUMPTION OF NEWSPRINT

Countries	Producing Capacity, Short Tons	Consumption, Short Tons
Germany	530,000	300,000
[illegible]	300,000	450,000
[illegible]	150,000	210,000
Sweden	185,000	30,000
Finland	150,000	10,000
[illegible]	110,000	10,000
Other European countries	200,000	110,000
Total (Europe)	1,625,000	1,120,000
[illegible]	1,500,000	2,000,000
[illegible]	1,000,000	130,000
[illegible]	150,000	[illegible]
All other countries	40,000	[illegible]
Total (world)	4,315,000	[illegible]

item is the size of the Canadian production figure—from 150,000 tons in 1909 to about 1,000,000 in 1922. This arises principally from the Canadian provincial pulpwood embargoes, which make Canadian Crownland pulpwood unavailable for American mills. It is estimated that over half of the capital invested in Canadian mills is of American origin.

Still another table is of interest. It shows exports from the principal newsprint countries in 1913, 1920 and 1921.

EXPORTS OF NEWSPRINT IN 1913, 1920, AND 1921, METRIC TONS

Countries	1913	1920	1921
Germany	69,000	45,000	109,000
Finland	70,000	90,000	94,000
Sweden	62,000	116,000	112,000
Norway	98,000	77,000	46,000
Canada	70,000	79,000	47,000
United States	46,000	42,000	15,000

It shows the signal advance of Germany and Finland as production centers. Finland, it is stated, is likely to be a significant factor because of low production costs and the complete absence of labor troubles. These two countries, together with the Scandinavian countries, are bound to be factors in the American market. An interesting indication of this is the formation of selling organizations for groups of mills in this country. This closer relation plus the fact that newsprint is on the free list makes foreign competition here a certainty.

Centralized Export Facilities for Flour

Successful culmination of a project whereby tidewater terminal facilities are provided for export shipments of flour, is noted in the Oct. 25 issue of the *Northwestern Miller*.

On Oct. 21 the huge pier which constituted the Oregon Ave. Army Base in Philadelphia was dedicated to the use of the millers of the United States. The ceremonies which marked the formal opening of the pier were attended by millers from central states and the Middle West, officials of the Millers' National Federation, Eastern seaboard members of the flour trade, and representatives of transportation, banking and other financial interests.

The pier is 1,500 ft. long by nearly 200 ft. wide, accommodating two factory fireproof warehouses approximately 1,480 ft. long by 100 ft. wide, with a total flour storage capacity of 750,000 to 1,000,000 bbl. Fire walls divide each warehouse into five sections and each of the ten sections is served by double trackage full length. Each warehouse loads direct to boats on the full length of 1,500 ft. The pier is leased by the United States Shipping Board to an operating company, the Tidewater Terminal Co., headed by Harvey C. Miller. These facilities will enable export shipments of flour to be handled more nearly on the same basis as export wheat. The storage and handling facilities will also be available for making reshipments to domestic points so that the terminal need not be idle during periods of slack export trade.

The New York Market

NEW YORK, Nov. 6, 1922.

The alkali export market has again shown signs of buying interest, and leading dealers have marked up quotations. Italy and Japan have been the largest purchasers, but the demand is fairly widespread over various foreign countries. This is the first time that caustic soda has braced up during the past 4 months and the fact that this product is in some quarters regarded as the barometer of the chemical list has led large factors to believe that the industry will continue on its upward trend. Another important feature uncovered during the week was the announcement of bichromate prices by some producers over 1923. Manufacturers of chloroform advanced prices 10c. per lb., due to "increased costs of production." Producers of chlorate of soda increased prices ¼c. per lb. at the works. Formaldehyde was again advanced by makers and the condition of the spot and nearby shipment market is exceedingly firm. White arsenic still continues in excellent demand and prices are firmly maintained. Permanganate of potash was materially higher on spot and importers stated that inquiries were more numerous than at any other time during the previous month. Barium chloride showed an easier tendency on spot. The market, in general, has continued to show complete signs of strength and steadiness. Declines were few and of only minor importance and sellers were quite satisfied with the volume of passing business.

GENERAL AND SPECIAL CHEMICALS

Arsenic—The demand was very active and the general tone remained firm. Sales of spot goods were reported at 10¾@11c. per lb., with shipments held at 10½c. Stocks in warehouses are very scarce.

Barium Chloride—There has been much stronger competition in this product and prices are somewhat easier. Material on spot was quoted around $95@$100 per ton.

Bichromate of Soda—Sales of spot goods were recorded at 7½@7¾c. per lb. Leading factors quoted shipments over next year at 7½@7¾c. per lb. There were several rumors that other producers were offering contracts as low as 7@7¼c. per lb. The demand was moderate during the interval.

Caustic Soda—The condition of the export market has shown considerable improvement and prices were advanced to $3.60 per 100 lb. Domestic prices remain at $3.75@$4 per 100 lb. ex-store.

Chlorate of Potash—Most dealers were somewhat higher at 7¾@8c. per lb. for the powdered. Domestic producers are quite firm in their views at 8½@9c. per lb., f.o.b. works.

Chlorate of Soda—Leading producers have advanced quotations to 6½c. per lb., f.o.b. works, and report a strong market at this level. Imported spot goods are bringing 6¾@7c. per lb. for round lots. Demand is quite active.

Chloroform—Producers of U.S.P. material have announced a new advance of 10c. per lb. Spot material is now quoted at 35c. per lb. The advance is due to the increased cost of manufacturing.

Formaldehyde—Spot and shipment material has again been advanced and leading factors are quoting 14c. per lb. f.o.b. works, carload lots. The tone of the market is exceptionally firm.

Permanganate of Potash—Prime U.S.P. spot goods were quoted higher and the best figure was 16½c. per lb. The range was from 16½@17c. per lb. Demand continues quite steady.

Prussiate of Soda—Several odd lot sales were reported at 22¾@23c. per lb. The tone of the market was somewhat irregular during the week. Imported goods for shipment held around 23c. per pound.

COAL-TAR PRODUCTS

The coal-tar products industry has shown a steady improvement and producers state that business has increased considerably during the entire month of October. The crude products have shown the most noteworthy gains and products in several instances were heavily sold ahead. Phenol, cresylic acid and benzene were the leaders of this group. Among the intermediates, beta naphthol prices were advanced and spot offerings were relatively light. Dimethylaniline was advanced owing to added costs of manufacture and a much improved demand. Ortho-amidophenol was also quoted higher under the same conditions. Salicylic acid showed material gains during the interval, with U.S.P. goods in very light supply on spot.

Aniline Oil—Dealers were asking 16½@17c. per lb. for spot material, although producers still quoted 16c. per lb., f.o.b. works. Offerings were somewhat lighter with improved demand.

Beta Naphthol—Spot goods are very scarce and as high as 26c. per lb. has been paid. The general range was around 25@26c. per lb. Recent heavy buying has diminished surplus stocks.

Dimethylaniline—There has been a moderate inquiry noted at 34@35c. per lb. The new advance is due to higher costs of production.

The St. Louis Market

ST. LOUIS, Oct. 31, 1922.

The market in this locality remains very active, with orders continuing to increase in volume. Furthermore, the market has maintained a very steady tone since our last report. Transportation facilities are still very poor and no relief is in sight for some time.

ALKALIS

The *caustic soda* market is, and has been for some time, very quiet. Apparently no large volume of business is being done, practically all purchases being confined to 5- and 10-drum lots. Prices are as of our last report, with no tendency to weaken. Perhaps the steadiness in value is due to the fact that rock bottom has been reached and lower prices could come only by way of sacrifice on the part of manufacturers. What has just been said for caustic can be repeated with emphasis for *soda ash* and *bicarbonate of soda*. Prices hang around the same level and business moves with the same momentum. *Sal soda*, while still maintaining its price of 2 weeks ago, is moving better recently. One jobber reports heavy sales of both package goods and barrels, apparently quite a volume of this item having changed hands recently.

GENERAL AND SPECIAL CHEMICALS

Heavy mineral acids continue to improve and there has been a steady hardening of prices. The *phenol* situation remains firm and inquiry continues to be very heavy. The *citric acid* situation remains unchanged, the demand being only routine and sales confined to small quantities. *Acid tartaric* is in better demand since our last report. The *white arsenic* market is exceedingly strong and supplies are becoming scarcer, the market ranging from 10½@12½c. f.o.b. New York in carload lots. Manufacturers of *chloroform* advanced their prices 10c. on Saturday of last week. A fairly good call is noted for *cream of tartar*. The demand for *copperas* is still very heavy; producers are unable to meet it owing to the curtailment of production. The demand for *epsom salts* is very light and supplies are readily obtainable, prices ranging from $2.50@$2.60 per 100 lb. *Glycerine* is still maintaining the same firmness of 2 weeks ago—18½c. in drums—and is moving in good volume. Apparently there is no letdown in sight and 20c. glycerine before the end of the year is to be expected. *Sulphur*, while still selling at the abnormally low price of 2 weeks ago, is moving in large volume through the natural channels. *Zinc dust* is now being quoted at from 10@10½c. f.o.b. New York in carload lots and a strong market is reported. There has been no change in quotations for *zinc sulphate* since our last report.

VEGETABLE OILS AND NAVAL STORES

Turpentine continues to advance and reached $1.72 this week. No one seems to know or even be willing to venture a guess as to where this item will stop. *Castor oil* has finally had a relapse and has started downward. A reduction of ½c. per pound was recently made by the manufacturers, but we do not expect any further decline, since the demand is very active. *Linseed oil* has not changed in price. A good volume of business is being done through the natural channels, and the market seems to be safely in the producers' hands.

PAINT MATERIALS

Nothing of note has happened in this market since our last report. Prices have not changed and business at this time is somewhat slow.

The Iron and Steel Market

PITTSBURGH, Nov. 3, 1922.

Steel mill operations are at approximately the same rate as a week ago, and indeed there has been little variation since late in September, production being about 70 per cent of capacity.

Car supplies for shipping mill products have improved a trifle farther. Current production is being shipped without much difficulty, and there is a gradual diminution of the piles of steel accumulated when car shortages were serious. There are still many embargoes, making proper distribution difficult, but embargoes are not as numerous or widespread as a few weeks ago.

The chief point about the transportation situation is the danger of movement being greatly slowed down by the appearance of inclement weather. Most of the roads, if not all, are in precarious position and cannot stand any weather handicaps.

FINISHED STEEL MARKETS QUIET

The finished steel markets are extremely quiet. They have been quiet for several weeks, indeed, and the present state is really one of decided dullness. The strongest lines are sheets and tubular goods. In sheets the independents are booking nearly as much as they are shipping, but their order books are gradually decreasing and some have considerably less than a month's production ahead. In tubular goods there is not a great deal of new buying, but there is pressure upon mills for better deliveries against old orders, particularly for butt weld black and galvanized merchant pipe, demand for which has been extremely heavy on account of the boom in garage and dwelling house construction.

Delivery premiums on bars, shapes, plates and sheets are still less important than a week ago, their almost complete disappearance reflecting the early deliveries many mills are now able to offer on new orders, by reason of their having had heavy shipments of late, with little booking of new business.

FINISHED STEEL PRICES

Regular prices on finished steel products are as follows: Bars, shapes and plates, 2c.; hoops, 2.90@3c.; wire, 2.45c.; nails, $2.70; tin plate, $4.75; merchant steel pipe, 66 per cent basing discount; black sheets, 3.35@3.50c.; galvanized sheets, 4.35@4.50c.

The American Sheet & Tin Plate Co. will probably name prices next week for sheets for first quarter and tin plate for first half of the new year. Recently prospects were plain that advances would be announced in most cases, but the prospect is now considerably less certain, because other products are now likely to decline rather than advance when they again move.

A few weeks ago it was difficult to buy sheet bars at $40. This week there are a half dozen or more sellers offering tonnages. Definite prices are not quoted, but it is considered certain that purchases could be made at not above $38. There is no regular inquiry. Predictions are that the sheet bar market for first quarter delivery, when developed eventually, will be at not above $35.

COAL AND COKE

Coal prices in the Pittsburgh and Connellsville markets are a shade firmer than a week ago, steam being quotable at $3.25@$3.50 rather than at $3@$3.50. Good Youghiogheny gas coal is stronger, at $4.50 for mine-run and $5@$5.50 for screened. At the insistence of Fuel Director Spens operators of the Pittsburgh district have agreed to limit their price on domestic 1¼-in. lump to $4.50 and assume that for metallurgical coal they may feel free to get all the market will give them. The reduction in domestic coal may have had something to do with the stiffening in other grades.

Connellsville coke is a shade firmer than a week ago. Odd lots on track awaiting shipping instructions and commonly known as "distress coke" continue to go at about $7.50, while a regular supply over a week or two may possibly command $8.50 rather than the $8 quotable a week ago. The market has an undertone of strength that cannot be attributed to increasing demand and is in face of increasing production. The condition probably arises from a number of consumers having decided, on the recent break from $12 to $8, that they would do better to close to the end of the year than await any further decline.

PIG IRON

Pig iron continues to present a stagnant market. Prices are in a general process of readjustment, which may require several months for completion. Meanwhile consumers, whose requirements appear smaller than formerly, are disposed to buy only for immediate requirements, and in the absence of large inquiry little competition occurs between sellers. Bessemer continues to sell in small lots at $33 valley, and foundry in small lots at $30 valley. Basic, which was at $30 for several weeks, has sold at $29 valley in a lot of about a thousand tons. There is no basic inquiry now and the chances are that the next inquiry will develop a lower price.

Sulphuric, 66 deg., drums	ton	19.00 – 20.00	20.50 – 21.00
Sulphuric, 66 deg., carboys	ton	..... –	..... – .....
Sulphuric, fuming, 20 per cent (oleum) tank cars	ton	19.00 – 20.00	..... – .....
Sulphuric, fuming, 20 per cent (oleum) drums	ton	22.00 – 22.50	23.00 – 24.00
Sulphuric, fuming, 20 per cent (oleum) carboys	ton	31.00 – 32.00	33.00 – 34.00
Tannic, U. S. P.	lb.	..... –	.60 – .75
Tannic (tech.)	lb.	.40 – .45	.46 – .50
Tartaric, imported crystals	lb.	..... –	.31 – .31¼
Tartaric acid, imported, powdered	lb.	..... –	.31½– .32
Tartaric acid, domestic	lb.	..... –	..... – .32
Tungstic, per lb. of WO	lb.	..... –	1.00 – .110c
Alcohol, ethyl (Cologne spirit)	gal.	..... –	4.75 – 4.95
Alcohol, methyl (see methanol)		..... –	..... – .....
Alcohol, denatured, 188 proof No. 1	gal.	..... –	.36 – .38
Alcohol, denatured, 188 proof No. 5	gal.	..... –	.36 – .38
Alum, ammonia, lump	lb.	.03½– .03¾	.04 – .04¼
Alum, potash, lump	lb.	.03½– .03¾	.04 – .04½
Alum, chrome lump	lb.	.05 – .05¼	.05½– .06
Aluminum sulphate, commercial	100 lb.	1.50 – 1.65	1.70 – 2.25
Aluminum sulphate, iron free	lb.	.02½– .02¾	.03 – .03¼
Aqua ammonia, 26 deg., drums(750 lb.)	lb.	.06¾– .07¼	.07½– .08
Ammonia, anhydrous, cyl.(100-150 lb.)	lb.	.30 – .30½	.30½– .31
Ammonium carbonate, powder	lb.	.08¼– .08½	.09 – .09½
Ammonium nitrate	½ lb.	.06 – .06½	.06¾– .07½
Amylacetate tech	gal.	..... –	2.35 – 2.50
Arsenic, white, powdered	lb.	.10 – .11	.11½– .11½
Arsenic, red, powdered	lb.	.12½– .12¾	.13 – .13½
Barium carbonate	ton	75.00 – 77.00	78.00 – 80.00
Barium chloride	ton	95.00 –100.00	102.00 –105.00
Barium dioxide (peroxide)	lb.	.20 – .21	.21¼– .22
Barium nitrate		.09 – .09¼	.09½– .10
Barium sulphate (precip.) (blanc fixe)	lb.	.04 – .04¼	.04¾– .04¾
Blanc fixe, dry	lb.	.04 – .04½	..... – .....
Blanc fixe, pulp	ton	45.00 – 55.00	..... – .....
Bleaching powder	100 lb.	2.00 – 2.10	2.15 – 3.25
Blue vitriol (see copper sulphate)		..... –	..... – .....
Borax	lb.	.05½– .05¾	.06 – .06¾
Brimstone (see sulphur, roll)		..... –	..... – .....
Bromine	lb.	.27 – .38	.28½– .35
Calcium acetate	100 lb.	3.00 – 3.15	3.20 – 3.50
Calcium carbide	lb.	.04½– .04¾	.05 – .05¼
Calcium chloride, fused, lump	ton	22.00 – 23.00	23.50 – 27.00
Calcium chloride, granulated	lb.	.01½– .01¾	.02 – .02¼
Calcium peroxide	lb.	..... –	1.40 – 1.50
Calcium phosphate, tribasic	lb.	..... –	.15 – .16
Camphor	lb.	..... –	.88 – .90
Carbon bisulphide	lb.	.07 – .07¼	.07½– .07¾
Carbon tetrachloride, drums	lb.	.10 – .10¼	.10½– .12
Carbonyl chloride, (phosgene)	lb.	..... –	.60 – .75
Caustic potash (see potassium hydroxide)		..... –	..... – .....
Caustic soda (see sodium hydroxide)		..... –	..... – .....
Chalk, precip.—domestic, light	lb.	.04¼– .04½	..... – .....
Chalk, precip.—domestic, heavy	lb.	.03½– .03¾	..... – .....
Chalk, precip.—imported, light	lb.	.04½– .05	..... – .....
Chlorine, gas, liquid-cylinders (100 lb.)	lb.	.05 – .05½	.05¾– .06
Chloroform	lb.	..... –	.35 – .38
Cobalt oxide	lb.	..... –	2.00 – 2.10
Copperas	ton	21.00 – 22.00	23.00 – 30.00
Copper carbonate, green precipitate	lb.	.21 – .21½	.22 – .22½
Copper cyanide	lb.	..... –	.58 – .600
Copper sulphate, crystals	100 lb.	5.75 – 6.00	6.10 – 6.504
Cream of tartar	lb.	..... –	.25½– .26
Epsom salt (see magnesium sulphate)		..... –	..... – .....
Ethyl acetate com. 85%	gal.	..... –	.72 – .75
Ethyl acetate, pure (acetic ether, 98% to 100%)	gal.	..... –	.90 – .95
Formaldehyde, 40 per cent	lb.	.14 – .14½	.14½– .14¾
Fullers earth, f.o.b. mines	net ton	16.00 – 17.00	..... – .....
Fullers earth—imported powdered	net ton	30.00 – 32.00	..... – .....
Fuse oil, ref.	gal.	..... –	2.75 – 2.90
Fusel oil, crude	gal.	..... –	1.65 – 1.85
Glauber's salt (see sodium sulphate)		..... –	..... – .....
Glycerine, c.p. drums extra	lb.	..... –	.18½– .18¾
Iodine, resublimed	lb.	..... –	4.40 – 4.50
Iron oxide, red	lb.	..... –	.12 – .18
Lead acetate, white crystals	lb.	..... –	.11½– .12½
Lead arsenate, powd.	lb.	.13 – .13½	.13½– .14½
Lead nitrate	lb.	..... –	.15 – .20
Litharge	lb.	.07½– .08	.08¾– .09
Magnesium carbonate, technical	lb.	.06 – .06½	.06½– .07¾
Magnesium sulphate, U.S.P.	100 lb.	2.50 – 2.65	2.70 – 3.50
Magnesium sulphate, technical	100 lb.	..... –	1.00 – 1.80
Methanol, 95%	gal.	..... –	.90 – .92
Methanol, 97%	gal.	..... –	.92 – .94
Nickel salt, double	lb.	..... –	.11 – .11½
Nickel salt, single	lb.	..... –	$0.12 –$0.12½
Phogene (see carbonyl chloride)		..... –	..... – .....
Phosphorus, red	lb.	..... –	.40 – .45
Phosphorus, yellow	lb.	..... –	.30 – .35¼
Potassium bichromate	lb.	$0.10 – .10½	.10½– .11
Potassium bromide, granular	lb.	..... –	.17 – .23
Potassium carbonate, U. S. P.	lb.	.12 – .12½	.13 – .16
Potassium carbonate, 80–85%	lb.	.06 – .06¼	.06½– .06¾
Potassium chlorate, powdered and crystals	lb.	.07¾– .08	.08¼– .09
Potassium cyanide	lb.	..... –	.55 – .57
Potassium hydroxide (caustic potash)	100 lb.	6.25 – 6.50	6.60 – 7.00
Potassium iodide	lb.	..... –	3.45 – 3.55
Potassium nitrate	lb.	.06½– .06¾	.07 – .08
Potassium permanganate	lb.	.16½– .16¾	.17 – .17½
Potassium prussiate, red	lb.	..... –	.95 – 1.00
Potassium prussiate, yellow	lb.	.37¾– .38	.38¼– .38½
Rochelle salts (see sodium potas. tartrate)		..... –	..... – .....
Salammoniac, white, granular	lb.	.06¾– .06¾	.07 – .07¼
Salammoniac, gray, granular	lb.	.08¼– .08½	.08¾– .09
Salsoda	100 lb.	1.20 – 1.40	1.45 – 1.60
Salt cake (bulk)	ton	25.00 –27.00	..... – .....
Soda ash, light, 58 per cent flat, bags, contract	100 lb.	1.60 – 1.67	2.00 – 2.25
Soda ash, light, 58 per cent flat, bags, resale	100 lb.	1.75 – 1.80	1.85 – 2.35
Soda ash, dense, in bags, resale	100 lb.	1.85 – 1.90	1.95 – 2.40
Sodium acetate	lb.	.08 – .08¼	.08½– .09
Sodium bicarbonate	100 lb.	1.75 – 1.85	1.90 – 2.30
Sodium bichromate	lb.	.07½– .07¾	.08 – .08½
Sodium bisulphate (nitre cake)	ton	4.50 – 4.60	4.65 – 5.50
Sodium bisulphite powdered, U.S.P.	lb.	.04¼– .04¼	.04¾– .05¼
Sodium chlorate	lb.	.06¾– .07	.07¼– .07½
Sodium chloride	long ton	12.00 –13.00	..... – .....
Sodium cyanide	lb.	.19½– .21	.21½– .25
Sodium fluoride	lb.	.09¾– .10	.10¼– .10½
Sodium hydroxide (caustic soda) solid, 76 per cent flat, drums, contract	100 lb.	3.35 – 3.40	3.75 – 4.00
Sodium hydroxide (caustic soda) solid, 76% flat, drums, resale	100 lb.	3.60 – 3.65	3.70 – 4.00
Sodium hydroxide (caustic soda), ground and flake, contracts	100 lb.	3.80 – 3.90	4.25 – 4.40
Sodium hydroxide (caustic soda) ground and flake, resale	100 lb.	4.00 – 4.15	4.40 – 4.60
Sodium hyposulphite	lb.	.02½– .02¾	.03 – .03½
Sodium nitrite	lb.	.09 – .09¼	.09½– .10
Sodium peroxide, powdered	lb.	.28 – .30	.31 – .35
Sodium phosphate, dibasic	lb.	.03½– .04	.04¼– .04½
Sodium potassium tartrate (Rochelle salts)	lb.	..... –	.18 – .21
Sodium prussiate, yellow	lb.	.22½– .23	.23¼– .23½
Sodium silicate, (40 deg. in drums)	100 lb.	.80 – 1.00	1.05 – 1.25
Sodium silicate, (60 deg. in drums)	100 lb.	2.25 – 2.40	2.45 – 2.75
Sodium sulphate, crystals (glaubers salt)	100 lbs.	.85 – .95	1.00 – 1.40
Sodium sulphide, fused, 60-62 per cent (conc.)	lb.	.04 – .04¼	.04½– .05
Sodium sulphite, crystals	lb.	.03¾– .03⅞	.03¾– .04½
Strontium nitrate, powdered	lb.	.09½– .10	.10¼– .12
Sulphur chloride, yellow	lb.	.04½– .05	.05¼– .06
Sulphur, crude	ton	18.00 –20.00	..... – .....
Sulphur dioxide, liquid, cylinders extra	lb.	.08 – .08½	.09 – .10
Sulphur (sublimed), flour	100 lb.	..... –	2.25 – 3.10
Sulphur, roll (brimstone)	100 lb.	2.00 – 2.15	2.20 – 2.70
Talc—imported	ton	30 00 –40.00	..... – .....
Talc—domestic powdered	ton	18 00 –25.00	..... – .....
Tin bichloride	lb.	.10 – .10¼	.10½– .10½
Tin oxide	lb.	..... –	.39 – .40
Zinc carbonate	lb.	.14 – .14½	.14¾– .15½
Zinc chloride, gran.	lb.	.07 – .07½	.07¾– .08
Zinc cyanide	lb.	.42 – .44	.45 – .47
Zinc oxide, XX	lb.	.07½– .08	.08¼– .08½
Zinc sulphate	100 lb.	2.75 – 3.00	3.05 – 3.30

Coal-Tar Products

NOTE—These prices are for original packages in large quantities f.o.b. N.Y.:

Alpha-naphthol, crude	lb.	$0.95 — $1.00
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.29 — .31
Aniline oil, drums extra	lb.	.16¼— .17
Aniline salts	lb.	.22 — .24
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.25 — 1.35
Benzene, pure, water-white, in drums (100 gal.)	gal.	.30 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.28 — .32
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.80 — .85
Benzoic acid, U.S.P.	lb.	.72 — .75
Benzoate of soda, U.S.P.	lb.	.57 — .65
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech.	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.53 — .55
Beta-naphthol, tech	lb.	.25 — .26
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Carbazol	lb.	.75 — .90
Cresol, U. S. P., in drums (100 lb.)	lb.	.14 — .20
Ortho-cresol, in drums (100 lb.)	lb.	.18 — .22
Cresylic acid, 97–99%, straw color, in drums	gal.	.60 — .65
Cresylic acid, 95-97%, dark, in drums	gal.	.55 — .58
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.50 — .60
Dimethylaniline	lb.	.34 — .36
Dinitrobenzene	lb.	.20 — .22
Dinitroclorbenzene	lb.	.21 — .22
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.32 — .34
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.85 — .90
Diphenylamine	lb.	.54 — .56
H-acid	lb.	.72 — .75
Meta-phenylenediamine	lb.	.90 — 1.00
Monochlorbenzene	lb.	.08 — .10
Monoethylaniline	lb.	.95 — 1.10
Naphthalene crushed, in bbls.	lb.	.06 — .06½
Naphthalene, flake	lb.	.06½— .07
Naphthalene, balls	lb.	.07½— .08
Naphthionate of soda	lb.	.58 — .65
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12

Nitro-naphthalene	lb.	$0.30 —	$0.35
Nitro-toluene	lb.	.15 —	.10
N-W acid	lb.	1.20 —	1.30
Ortho-amidophenol	lb.	2.25 —	2.30
Ortho-dichlor-benzene	lb.	.17 —	.20
Ortho-nitro-phenol	lb.	.80 —	.85
Ortho-nitro-toluene	lb.	.12 —	.15
Ortho-toluidine	lb.	.12 —	.14
Para-amidophenol, base	lb.	1.20 —	1.25
Para-amidophenol, HCl	lb.	1.25 —	1.30
Para-dichlorbenzene	lb.	.17 —	.20
Paranitroaniline	lb.	.72 —	.80
Para-nitrotoluene	lb.	.55 —	.65
Para-phenylenediamine	lb.	1.55 —	1.60
Para-toluidine	lb.	.85 —	.90
Phthalic anhydride	lb.	.35 —	.38
Phenol, U. S. P., drums	lb.	.30 —	.32
Pyridine	gal.	1.60 —	1.75
Resorcinol, technical	lb.	1.50 —	1.55
Resorcinol, pure	lb.	2.00 —	2.10
R-salt	lb.	.55 —	.60
Salicylic acid, tech., in bbls	lb.	.33 —	.35
Salicylic acid, U. S. P	lb.	.38 —	.40
Solvent naphtha, water-white, in drums, 100 gal	gal.	.27 —	.32
Solvent naphtha, crude, heavy, in drums, 100 gal	gal.	.12 —	.14
Sulphanilic acid, crude	lb.	.24 —	.26
Tolidine	lb.	1.20 —	1.30
Toluidine, mixed	lb.	.30 —	.35
Toluene, in tank cars	gal.	.25 —	.28
Toluene, in drums	gal.	.30 —	.35
Xylidines, drums, 100 gal	lb.	.40 —	.45
Xylene, pure, in drums	gal.	.40 —	.45
Xylene, pure, in tank cars	gal.	.45 —	....
Xylene, commercial, in drums, 100 gal	gal.	.33 —	.35
Xylene, commercial, in tank cars	gal.	.30 —	....

Waxes

Prices based on original packages in large quantities f.o.b. N.Y.

Bayberry Wax	lb.	$0.20 —	$0.21
Beeswax, refined, dark	lb.	.30 —	.32
Beeswax, refined, light	lb.	.34 —	.35
Beeswax, pure white	lb.	.36 —	.40
Candellila, wax	lb.	.33 —	.34
Carnauba, No. 1	lb.	.39 —	.40
Carnauba No. 2, North Country	lb.	.24 —	.25
Carnauba, No. 3, North Country	lb.	.17 —	.18
Japan	lb.	.15 —	.16
Montan, crude	lb.	.03½ —	.04
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.04 —	.04¾
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.02½ —	.02¾
Paraffine waxes, refined, 118-120 m.p.	lb.	.03¾ —	.03½
Paraffine waxes, refined, 125 m.p.	lb.	.03¼ —	.03¾
Paraffine waxes, refined, 128-130 m.p.	lb.	.04 —	.04¼
Paraffine waxes, refined, 133-135 m.p.	lb.	.04½ —	.04¾
Paraffine waxes, refined, 135-137 m.p.	lb.	.05 —	.05¼
Stearic acid, single pressed	lb.	.09 —	.09¾
Stearic acid, double pressed	lb.	.09½ —	.09¾
Stearic acid, triple pressed	lb.	.10½ —	.10

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl	280 lb.	$6.90 —	....
Rosin E-I	280 lb.	6.95 —	....
Rosin K-N	280 lb.	7.00 —	$7.10
Rosin W. G.-W. W	280 lb.	7.75 —	8.25
Wood rosin, bbl	280 lb.	6.25 —	....
Spirits of turpentine	gal.	1.64 —	1.64
Wood turpentine, steam dist	gal.	1.35 —	....
Wood turpentine, dest. dist	gal.	1.25 —	....
Pine tar pitch, bbl	200 lb.	..... —	6.00
Tar, kiln burned, bbl. (500 lb.)	bbl.	..... —	12.50
Retort tar, bbl	500 lb.	..... —	11.00
Rosin oil, first run	gal.	.43 —	....
Rosin oil, second run	gal.	.51 —	....
Rosin oil, third run	gal.	.53 —	....
Pine oil, steam dist., sp.gr., 0.930-0.940	gal.		.90
Pine oil, pure, dest. dist	gal.		.85
Pine tar oil, ref., sp.gr. 1.025-1.035	gal.		.46
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla	gal.		.35
Pine tar oil, double ref., sp.gr. 0.965-0.990	gal.		.75
Pine tar, ref., thin, sp.gr., 1.080-1.960	gal.		.25
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990	gal.		.25
Pine wood creosote, ref	gal.		.52

Fertilizers

Ammonium sulphate, f.a.s., N. Y., double bags	100 lb.	3.55 —	3.65
Blood, dried, f.o.b., N. Y	unit	4.60 —	....
Bone, 3 and 50, ground, raw	ton	42.00 —	44.00
Fish scrap, dom., dried, f.o.b. works	unit	3.10 —	3.20
Nitrate of soda	100 lb.	2.35 —	2.45
Tankage, high grade, f.o.b. Chicago	unit	4.50 —	4.60
Phosphate rock, f.o.b. mines, Florida pebble, 68-72%	ton	3.50 —	4.00
Tennessee, 78-80%	ton	7.00 —	8.00
Potassium muriate, 80%	ton	33.00 —	34.00
Potassium sulphate	unit	1.00 —	....

Crude Rubber

Para—Upriver fine	lb.	$0 24 —	.24¼
Upriver coarse	lb.	.18¾ —	.19
Upriver caucho ball	lb.	.18 —	.18¼
Plantation—First latex crepe	lb.	.22¼ —	.22½
Ribbed smoked sheets	lb.	.22¼ —	.22½
Brown crepe, thin, clean	lb.	.20 —	.20½
Amber crepe No. 1	lb.	.20 —	.20½

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls	lb.	$0.12 —	$0.12½
Castor oil, AA, in bbls	lb.	.12½ —	.13
China wood oil, in bbls	lb.	.12½ —	.13
Cocoanut oil, Ceylon grade, in bbls	lb.	.08½ —	.08¾
Cocoanut oil, Cochin grade, in bbls	lb.	.08¾ —	.09
Corn oil, crude, in bbls	lb.	.09½ —	.09¾
Cottonseed oil, crude (f. o. b. mill)	lb.	.07½ —	....
Cottonseed oil, summer yellow	lb.	.10½ —	.10¾
Cottonseed oil, winter yellow	lb.	.11¼ —	.11½
Linseed oil, raw, car lots (domestic)	gal.	.89 —	.90
Linseed oil, raw, tank cars (domestic)	gal.	.86 —	.87
Linseed oil, boiled, in 5-bbl lots (domestic)	gal.	.90 —	.92
Olive oil, denatured	gal.	1.15 —	1.17
Palm, Lagos	lb.	.07 —	.07½
Palm, Niger	lb.	.06⅛ —	.06¼
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.08¼ —	.09
Peanut oil, refined, in bbls	lb.	.12½ —	.13
Rapeseed oil, refined in bbls	gal.	.77 —	.78
Rapeseed oil, blown, in bbls	gal.	.84 —	.85
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.11½ —	....
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.08¾ —	.09

FISH

Light pressed menhaden	gal.	$0.54 —	....
White bleached menhaden	gal.	.58 —	.59
Blown menhaden	gal.	.64 —	.65
Whale Oil, No. 1. crude, tanks, coast	gal.	.45 —	.48

Ferro-Alloys

Ferrotitanium, 15-18%, f.o.b. Niagara Falls, N. Y	net ton	$200.00 —	$225.00
Ferrochromium, per lb. of Cr contained, 6-8% carbon, carlots	lb.	.11 —	.12
Ferrochromium, per lb. of Cr contained, 4-6% carbon, carlots	lb.	.12 —	.13
Ferromanganese, 78-82% Mn, Atlantic seaboard	gross ton	67.50 —	69.00
Spiegeleisen, 19-21% Mn	gross ton	37.00 —	38.00
Ferromolybdenum, 50-60% Mo, per lb. of Mo	lb.	2.00 —	2.25

Industrial

Financial, Construction and Manufacturers' News

Industrial Developments

OILS—Martin & Co., Transportation Bldg., Chicago, Ill., have inaugurated operations at their new oil refinery at Osborne, Ind. Portions of the plant are still to be completed and equipment will be installed at an early date. The refinery will run on crude oil from the Pioneer field, Tex.

The Premier Refining Co., Oatsville, near Princeton, Ind., has placed its new gasoline-refining plant in operation and will develop maximum output at an early date. This is the first such refinery in Gibson County.

The Globe Petroleum Co., Los Angeles, Calif., is increasing production at its different plants, and exclusive of royalty plant leases, an average of 150,000 bbl. of oil per month will be maintained.

About 50 per cent of the independent oil refineries in Oklahoma are closed down or have curtailed operations, due to the general conditions in the mid-continent fields, according to an official statement made at the meeting of the Oklahoma Oil Jobbers' Association, Oklahoma City, Oct. 19.

The New England Refining Co. has advanced production at its Fall River, Mass., plant to a basis of 20,000 to 25,000 bbl. of crude oil through the stills per day.

RUBBER—The Studebaker-Wulff Rubber Co. has adopted a day and night basis of operation at its local plant, giving employment to a full working force. Extensions are planned to double the present capacity.

Negotiations are said to be in progress for the sale of the plant of the Philadelphia Rubber Works, 37th and Reed Sts., Philadelphia, Pa., to new interests, which propose to place the plant in operation at an early date. It has been closed since 1919.

PAPER—The Philadelphia Paper Mfg. Co., Philadelphia, Pa., has developed capacity operations and is now running on the basis of 500 tons per day. A wage advance of 15 per cent was recently made at the mill. About one-fourth of the output is being utilized at the plant of the Fiber Container Co., a subsidiary organization, which is also running full.

The Kieckhefer Container Co., Camden, N. J., is operating at full capacity at its paper and fiber plants, giving employment to regular working force. A new plant is being built at Delair, near Camden, and will be placed in service as soon as completed.

Every newsprint paper mill in Canada, totaling thirteen in all, is running on a full-capacity, full-time basis, with maximum output the highest in a number of years. For the first 7 months of the present year the production totaled 643,858 tons, or more than the total for any year prior to 1917. The Spanish River Paper Co., Ottawa, one of the largest producers, is running full in all departments of its mills.

IRON AND STEEL—The Bourne-Fuller Co., Cleveland, O., has blown in another furnace at its plant.

The American Bridge Co. has placed all furnaces in blast at its Pencoyd Works, Manayunk, Philadelphia, Pa., and will maintain on this basis for an indefinite period.

The Crane Iron Works, Catasauqua, Pa., is making improvements and repairs in its large blast furnace, and expects to have the unit ready for blast some time in December. The date of blowing in will be announced soon.

The American Steel & Wire Co., Cleveland, O., has blown in another furnace at its local mills.

The Eastern Steel Co., Pottsville, Pa., has placed its local plant on a full-production basis, and is said to have orders on hand to keep the six mills at this point for about 12 months to come. The Pottstown, Pa., furnaces of the company are also all on the active list.

The Carnegie Steel Co. has placed its Farrell, Pa., works on a full-capacity schedule, and will maintain on this basis for an indefinite period.

The American Sheet & Tin Plate Co. has started up all of the forty hot mills at its Shenango Works, near New Castle, Pa.; ten of the mills have been idle for about 6 months past.

The Republic Iron & Steel Co., East Chicago, Ind., has closed its local mills for an indefinite period, due, primarily, to the decreased demand for bar iron. About 400 men will be released until further notice.

The Robesonia Iron Co., Reading, Pa., is arranging to blow in its large stack about Nov. 15. The plant has been idle for repairs to the furnace for a number of weeks past.

The American Sheet & Tin Plate Co. has placed the twelve hot mills in operation at its New Philadelphia, Pa., plans, after a short curtailment. About 350 men will be employed. The company has recently booked heavy orders in sheet bars.

Steel plants in all parts of the country are now running on a basis of about 75 to 80 per cent of normal. Increased working forces are being employed.

MISCELLANEOUS—The Barrett Co., Grays Ferry district, Philadelphia, Pa., manufacturer of coal-tar products, has adopted a capacity operating schedule at its plant, and will continue on this basis for an indefinite period. A full working force is employed.

The National Sulphur Co., Bayonne, N. J., has commenced operations at its new plant at North Akron, O., on a full-time production basis. The initial output is expected to be advanced at an early date. The company will remove its New York office to North Akron.

Brick-manufacturing plants in the vicinity of Atlanta, Ga., are making ready for a full-time production schedule immediately, following a shut-down due to the railroad car shortage. It is said that every plant in this district has orders ahead to insure capacity for a number of months to come.

The Henry Bower Chemical Mfg. Co., Manayunk, Philadelphia, Pa., is running on a full-capacity, full-time basis, with employment of normal working force. Less than 6 months ago the plant was practically closed down due to lack of orders. The orders on hand insure maximum operations for some time to come.

The Diamond State Fiber Co. has closed down its plant at West Conshohocken, Pa., temporarily, due to the demand of employees for a wage advance of 10 cents per hour, and the company's refusal to meet the request. More than 200 workers are affected by the shut-down.

The R. M. Hollingshead Co., Camden, N. J., manufacturer of soaps, leather dressings, etc., is increasing production at its plant and is now running at close to capacity.

The Chattanooga Coke & Gas Co., Chattanooga, Tenn., has resumed operations at its coke works, following a suspension for a number of weeks. Byproduct gas is also being furnished again to local consumers.

Construction and Operation

Alabama

TARRANT CITY—The Lehigh Portland Cement Co., Allentown, Pa., has awarded a contract to Dwight P. Robinson & Co., Inc., 125 East 46th St., New York, N. Y., for the erection of its proposed cement-manufacturing plant at Tarrant City, near Birmingham. It will be equipped for an annual production of 1,000,000 bbl., and is estimated to cost close to $1,500,000 with machinery. It is purposed to have the mill ready for operation in about 12 months.

California

ANAHEIM—Charles A. Criss is completing plans for the construction of a new plant at 315 South Vine St., for the manufacture of cement brick and art cement products. It will consist of three buildings.

LOS ANGELES—The W. P. Fuller Paint Co., Los Angeles, has awarded a contract to Lepper & Laisy, O. T. Johnson Bldg., for the erection of its proposed 2-story plant on Ave. 22, 120x125 ft., estimated to cost approximately $45,000.

FRESNO—The United Engine & Machine Co. recently organized with capital of $250,000, to merge the Sulprizio Machine Works, 507 Broadway, and the Fresno Pattern Works, 2137 Cherry St., has plans in progress for the erection of a 1-story foundry and molding shop, 100x150 ft., for iron and steel castings production. G. J. Dolan, Jr., is head.

LONG BEACH — The American Avenue Glas Co. has acquired a site on West 15th St., Inner Harbor district, 80x125 ft., for the erection of a new glass-manufacturing plant. Theodore J. Stein is president.

Connecticut

WEST HAVEN—The Sanderson Fertilizer Co. has filed plans for the erection of a new 1-story building at its plant.

BERLIN—The Stiles & Reynolds Co. plans for the rebuilding of the portion of its brick-manufacturing plant on Christian Lane, destroyed by fire, Oct. 23, with loss estimated at about $18,000.

HARTFORD—The Skat Co., Francis Ave., manufacturer of soap, soap powders, etc., has filed plans for the erection of a 2-story addition, 40x75 ft.

Florida

FORT LAUDERDALE — The International Sugar Co. has tentative plans under consideration for the construction of a new sugar refinery and mill on site near Fort Lauderdale. The proposed plant will have an initial capacity of about 1,500 tons per day, and is estimated to cost in excess of $500,000, with machinery. It is expected to commence work during the coming year. Howard L. Allen is general manager.

WEST PALM BEACH—Carl Riddel, city manager, is developing plans for the purchase of the artificial gas works now furnishing service to the city. When the plant is taken over, extensions and improvements will be made.

Illinois

GRANITE CITY—The Mepham Paint Co., East St. Louis, Ill., has plans in progress for the erection of a new plant on local site, 1-story, 100x100 ft., estimated to cost close to $100,000. It will be used primarily for copperas production.

CHICAGO — The Patterson-Sargent Co., 2025 Lumber St., manufacturer of paints and varnishes, has excavations under way for the erection of a new 4-story building at Lumber and Stewart Sts., 60x125 ft., and expects to have the structure ready for occupancy early in the coming spring. Additional land has been obtained, 75x200 ft., for proposed later extensions.

Indiana

EVANSVILLE—The Evansville Enameling Co., Fulton St., will take bids at once for the erection of its proposed 1-story addition, 50x85 ft., estimated to cost about $55,000, including equipment. Russ & Karges, Furniture Bldg., are architects.

EVANSVILLE — The Globe - Bosse - World Furniture Co. has had plans prepared for the construction of a 1-story plant addition, 45x160 ft., to be equipped for the manufacture of mirrors. Russ & Karges, Furniture Bldg., are architects.

Kansas

AUGUSTA—The White Eagle Oil & Refining Co., Wichita, Kan., has construction nearing completion on a new unit at its local refinery, to increase the capacity of the cracking stills. The extension will be placed in service at an early date.

Kentucky

ASHLAND—The American Rolling Mill Co., Middletown, O., has plans in progress for the erection of an addition to its local plant, to include a new sheet mill, jibbing mill and galvanizing works. Dwight P. Robinson & Co., Inc., 125 East 46th St., New York, N. Y., is engineer.

Louisiana

MONROE—The Louisiana Producing & Carbon Co. has plans under way for the construction of a new carbon and gasoline extraction plant, estimated to cost in excess of $150,000. The carbon works will comprise two individual plant units, the first of which will be ready for service early in 1923, and at which time erection of the second unit will be commenced. The complete plant will have a capacity of 8,000 lb. of carbon black per day. The gasoline plant will be of vertical absorption type, with treating capacity of 10,000,000 cu.ft. of gas per 24 hr. The company has recently increased its capital to $350,000 for the expansion. R. R. Beaman is president.

Maryland

CAMBRIDGE—Fire, Oct. 27, destroyed a portion of the plant of the Dorchester Fertilizer & Lime Co., Trenton St. and Cambridge Creek, with loss estimated at about $65,000. It is planned to rebuild at a later date. Lloyd Webster and John Skinner head the company.

BROOKLYN—The Arundel-Shope Brick Co., Pier 2, Pratt St., Baltimore, is perfecting plans for the erection of its proposed new brick-manufacturing plant on local site, to consist of a number of buildings with power house. Lawson L. Wagner is president and manager.

BALTIMORE — The Holtite Mfg. Co., Warner and Ostend Sts., manufacturer of rubber specialties, has plans in preparation for the erection of a new 1-story plant addition, 50x155 ft., to double, approximately, the present output. Stanislaus Russell, 11 East Lexington St., is architect.

BALTIMORE—Fire, Oct. 23, destroyed a large portion of the plant of the Porcelain Enamel & Mfg. Co., O'Donnell and 8th Sts., with loss estimated at about $400,000, including buildings and equipment. It is planned to rebuild. Heinrich Turk is president.

EASTON—The City Council is arranging plans for the purchase of the local artificial gas plant, and will operate as municipal property. It is proposed to issue bonds for extensions and improvements.

BALTIMORE—The Standard Oil Co. has filed plans for the erection of a 1-story asphalt works, 124x204 ft., at 2nd Ave. and 2nd St., estimated to cost about $40,000.

Massachusetts

BOSTON—The Tileston & Hollingsworth Co., River St., Hyde Park, has awarded a contract to the Aberthaw Construction Co., 7 School St., Boston, for the erection of a 1-story addition to its paper manufacturing plant, to cost about $30,000. George F. Hardy, 309 Broadway, New York, N. Y., is engineer.

SOMERSET—Fire, Oct. 24, destroyed a portion of the plant of the E. S. Parks Shellac Co., including drying department. An official estimate of loss has not been made.

Michigan

BAY CITY—Construction is being rushed on the new local plant of the Wildman Rubber Co., and is expected to have the structure ready for the machinery installation at an early date. It will be 4-story, 165x365 ft., and will be used primarily for automobile tire production.

Minnesota

MINNEAPOLIS—The Carter-Mayhew Mfg. Co., is planning for the construction of a new 1-story foundry at its mechanical works, 19th Ave., N.E., 60x100 ft., estimated to cost close to $30,000.

Missouri

SARCOXIE—The plant of the Sarcoxie Lime Kiln Co. has been acquired by H. T. Oltman and Charles Shull. The new owners will continue the operation of the property for the manufacture of commercial fertilizer products, and plan for extensions and improvements, including the installation of a new crushing plant.

New Jersey

SALEM—Fire, Oct. 27, destroyed a building at the plant of the Gayner Glass Works, with loss estimated at about $100,000, including stock, equipment, etc. The company specializes in the manufacture of bottles, jars, etc.

New York

BINGHAMTON—The American Hide & Leather Co. has disposed of its local tannery to the Endicott-Johnson Corp., manufacturer of footwear, which will continue the operation of the plant.

RICHMOND HILL, L. I.—The Unique Leather Goods Co., Jamaica Ave., has awarded a contract to the Ettinger Contracting Co., 44 Court St., Brooklyn, for the erection of a 2-story addition, 80x400 ft. William Higginson, 15 Park Row, New York, is architect.

BUFFALO—The Bethlehem Steel Co. is arranging an extension and improvement program for its local Lackawanna Steel works, estimated to cost in excess of $10,000,000, including buildings, machinery, etc. The initial work will comprise the modernizing of a number of plant departments.

North Carolina

HERTFORD—Fire, Oct. 22, destroyed a portion of the plant of the Eastern Cotton Oil Co., with loss estimated at about $35,000. It is planned to rebuild.

LEXINGTON—The Rodrain Electro-Metallurgical Co., Salisbury, N. C., has tentative plans under way for the construction of a new 3-story plant for gold refining at its Gold Hill mine, estimated to cost approximately $500,000. J. L. Mittenhuler heads the company.

Ohio

ELYRIA—Negotiations are under way for the purchase and reorganization of the Columbia Steel Co. A new company will be formed under the present name with capital of $1,500,000, and extensions and improvements made in the present plant, including the installation of improved processes of production in a number of departments. It is purposed to issue bonds for $750,000, a portion of the fund to be used for the expansion. C. E. Lozier, vice-president and general manager of the present organization, will head the new company.

Oklahoma

PONCA CITY—The Empire Refineries, Inc., will make additional extensions and improvements in its oil refining plant to cost close to $1,000,000. Work on an initial program calling for an investment of about $2,000,000 is now nearing completion, and new plant units will be placed in service at an early date. The refinery is now running on a basis of 4,000 bbl. per day.

MUSKOGEE—The Oklahoma Fabric & Rubber Co., recently organized with a capital of $2,500,000 by officials of the Allen Tire & Rubber Co., Allentown, Pa., has acquired a local building and site for the establishment of its proposed plant for the manufacture of tires and other rubber products. Extensions and improvements will be made in the present structure to cost in excess of $1,000,000, including machinery installation. The local Chamber of Commerce is interested in the project.

Oregon

GRANTS PASS—The Beaver Portland Cement Co., Portland, is reported to be planning for the construction of a new cement mill in the vicinity of Grants Pass, estimated to cost in excess of $750,000. The entire project will include the development of raw material properties in Josephine County and the construction of a private railroad line, to involve a total expenditure of about $1,200,000.

Pennsylvania

MCKEES ROCKS—The Federal Enameling & Stamping Co., Thompson Ave., is completing plans for the erection of a new 3-story plant addition. A portion of the structure will be equipped as a furnace department. C. E. Christian is in charge.

PITTSBURGH—The Pruett-Schaffer Chemical Co., Tabor St., manufacturer of paint, etc., has acquired a tract of vacant property at Lincoln Ave. and Ohio St., for $15,000, for future expansion.

Tennessee

COLUMBIA—The plant and property of the Ruhm Phosphate Co. have been purchased by J. P. Greenlaw and associates. The new owners plan for extensions and improvements in the grinding plant and other departments.

MEMPHIS—Fire, Oct. 22, destroyed a building at the plant of the Plough Chemical Co., with loss reported at about $125,000. It is expected to rebuild.

Texas

GONZALES—The Gonzales Cement Works, Inc., has plans under way for the erection of a new plant, 50x90 ft., with adjoining structure, 40x50 ft., for the manufacture of cement tile and kindred products. A. O. Neumann heads the company

JACKSONVILLE—The Jacksonville Cotton Oil Co. is reported to be planning for the rebuilding of its plant, totally destroyed by fire, Oct. 16. An official estimate of loss has not been announced.

TEXAS CITY—The Terminal Oil & Refining Co. is planning for extensions in its topping plant to more than double the present capacity. Work will be commenced at an early date. C. E. Robertson is superintendent.

Utah

SALT LAKE CITY—The Salt Lake Insecticide Co. is pushing construction on its new local plant for the treatment of ores from the properties of the Western Utah Copper Co. The plant is designed to recover the arsenic in the form of calcoum arsenate, utilizing lead or zinc oxide in the process. Dr. Frank W. Cameron is general manager.

Washington

VANCOUVER—The United States Molybdenum Metals, Ltd., operating in the St. Helens mining district, near Spirit Lake, has acquired the former shipyard property of the Standifer Shipbuilding Co., as a site for the erection of a new smelting and refining plant. Work will be commenced at an early date. Headquarters of the company are at 16 Natoma St., San Francisco, Calif.

SEATTLE — The Washington Iron Works will commence the immediate erection of a new 1-story foundry, 130x660 ft., for the production of iron and steel castings, estimated to cost about $90,000. Richard Ellis is company engineer.

West Virginia

WHEELING—Plans are being prepared for the construction of a new filtration plant at the municipal waterworks, and bids for equipment are expected to be asked early in December. The plant will have a capacity of 20,000,000 gal. With new power house, tanks and pumping station, the project will cost about $1,000,000. J. N. Chester, Union Bldg., Pittsburgh, Pa., is engineer.

Canada

MONTREAL — The Howard Smith Paper Mills, Ltd., has authorized plans for the construction of a new plant for the production of bleached soda pulp, to have an initial capacity of about 15,000 tons per annum.

New Companies

THE RENSSELAER PAPER CO., New York, N. Y., care of J. L. Holtzman, Woolworth Bldg., representative, has been incorporated with a capital of $50,000, to manufacture paper products. The incorporators are S. Berkman, A. Krissoff and M. Carberry.

THE AMERICAN VAT COLOR MFG. CO., 3223 Western Blvd., Chicago, Ill., has been incorporated with a capital of 4.500 shares of stock, no par value, to manufacture synthetic organic chemical products. Incorporators: William J. Loeffler, E. C. Kohlsaat and H. F. Clark.

THE CLINTON CHEMICAL CORP., Irvington, Newark, N. J., has been incorporated with a capital of $125,000, to manufacture chemical products, gasoline intensifiers, etc. The incorporators are Henry S. DeForest, Francis W. Wilcox and George F. Schmitt, 1045½ Clinton Ave., Irvington. The last noted represents the company.

THE CHEMICAL PRODUCTS CORP., Providence, R. I., has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts. The incorporators are James B. Littlefield, Fred A. Otis and Gilbreth Brown, 24 Audubon Ave., Providence. The last noted represents the company.

THE CRYSTAL SOAP & CHEMICAL CO., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws with capital of $100,000, to manufacture chemical products, soaps and kindred specialties.

THE MORRIS PETROLEUM CO., Somerset, Ky., has been incorporated with a capital of $25,000, to manufacture petroleum products. The incorporators are Jackson Morris and Leslie Combest, Somerset; and Henry J. Stites, Louisville, Ky.

THE CASS CHEMICAL CO., 4405 Cass Ave., Detroit, Mich., has been organized under state laws to manufacture chemical specialties, synthetic products, etc. The incorporators are Edward Hirschfeld and Benjamin Meyers.

THE YOUNGSTOWN HIDE & TALLOW CO., Youngstown, O., has been incorporated with a capital of $25,000, to manufacture tallow, greases, and kindred specialties. The incorporators are George J. Bickler and L. J. Ferbstein, both of Youngstown.

THE RED BALL REFINING CO., 1400 Consumers' Bldg., Chicago, Ill., has been incorporated with a capital of $100,000, to manufacture refined oils, etc. The incorporators are F. G. Howell, B. Groh and L. E. Walther.

THE DRURY MFG. CO., Mineola, L. I., care of T. C. Horton, Rahway, N. J., representative, has been incorporated with a capital of $15,000, to manufacture brick, tile and kindred burned clay products. The incorporators are W. F. Drury and R. C. Hunt.

THE SEMINOLE PRODUCTS CO., Jacksonville, Fla., has been incorporated with a capital of $400,000, to manufacture cement products. J. R. Nordquest is president; and Harry Mills, secretary, both of Jacksonville.

THE DEN-WAL MFG. CO., Newark, N. J., has been incorporated with a capital of $100,000, to manufacture chemicals and chemical byproducts. The incorporators are H. L. Davis, Nathan P. Walton and James A. Dennis, 8 Jefferson St., Newark. The last noted represents the company.

THE LOUISVILLE PETROLEUM REFINING CO., Louisville, Ky., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., representative, has been incorporated with a capital of $500,000, to manufacture refined petroleum products and byproducts.

THE SHO-FORM CO., Buffalo, N. Y., care of Persons & Blair, White Bldg., Buffalo, representatives, has been incorporated with a capital of $25,000, to manufacture soap products. The incorporators are W. F. and E. G. Messing, and L. E. Moschel, all of Buffalo.

THE STENSEL-SPEAR MICA CO., New York, N. Y., care of Oscar Lowenstein, 27 Cedar St., New York, representative, has been incorporated with a capital of $12,000, to manufacture mica products. The incorporators are H. S. Spear, E. and A. Stensel.

THE VAL-O CHEMICAL CO., 823 North Broadway, Decatur, Ill., has been incorporated with a capital of $50,000, to manufacture chemical specialties. The incorporators are Val H. Chronister, H. M. McMillan and N. Stookey.

THE ADANAC-TEXAS OIL CO., San Antonio, Tex., has been incorporated with a capital of $150,000, to manufacture petroleum products. The incorporators are B. W. Somers, C. L. Watson and J. D. Reese, all of San Antonio.

THE EASTERN REFINING CO., New York, N. Y., care of the United States Corporation Co., 65 Cedar St., New York, representative, has been incorporated under Delaware laws with capital of $50,000, to manufacture refined petroleum products.

THE TEXARKANA PAINT CO., Texarkana, Ark., has been incorporated with a capital of $25,000, to manufacture paint, varnish and kindred products. The incorporators are B. H. Kuhl, H. H. and J. H. Harrell, all of Texarkana.

THE ROYAL PAPER PRODUCTS CO., New York, N. Y., care of M. I. Murzin, 233 Broadway, representative, has been incorporated with a capital of $25,000, to manufacture paper specialties. The incorporators are I. Levy, D. and C. Rosenthal, all of New York.

THE MOHAWK OIL CO., San Francisco, Cal., has been incorporated with a capital of $3,000,000, to manufacture petroleum products. The incorporators are C. E. Ward, L. B. Cook, F. R. Stewart and Joseph C. Meyerstein, 57 Post St., San Francisco. The last noted represents the company.

THE NOUN CHEMICAL CO., New York, N. Y., care of J. F. Neuman, Jr., 601 West 144th St., New York, representative, has been incorporated with a capital of $5,000, to manufacture chemical specialties. The incorporators are E. D. Neuman and H. C. Harvey.

THE NATIONAL TILE WORKS, INC., New Brunswick, N. J., has been incorporated with a capital of $25,000, to manufacture ceramic tile products. The incorporators are Samuel and Joseph LiCausi, 146 Neilson St., New Brunswick. The last noted represents the company.

THE MCELMORE COVE OIL CO., Chickamauga, Ga., has been incorporated with a capital of $50,000, to manufacture refined oil products. The incorporators are J. P. Dunaway, Chickamauga; Frank P. Case and D. H. Mitchell, both of Chattancoga, Tenn.

THE PHARAOH PARCHMENT CO., San Francisco, Calif., has been incorporated with a capital of $50,000, to manufacture paper products. The incorporators are E. Hepner, G. E. Lund, J. Politizer and George A. Connolly, Mills Bldg., San Francisco. The last noted represents the company.

THE PALADO OIL CO., Houston, Tex., has been incorporated with a capital of $50,000, to manufacture petroleum products. The incorporators are F. H. Sheffield, Claude Kavanaugh and H. P. Porter, all of Houston.

THE M. A. WELLIN OIL CO., Syracuse, N. Y., care of C. S. Carr, White Memorial Bldg., Syracuse, representative, has been incorporated with a capital of $50,000, to manufacture oil products. The incorporators are M. A., F. and J. Wellin.

THE J. & J. CHEMICAL CO., Buffalo, N. Y., care of Clarence MacGregor, Ellicott Sq., Buffalo, representative, has been incorporated with a capital of $5,000, to manufacture chemicals and chemical byproducts. The incorporators are J. Sansone, and J. Barone.

THE VIM OIL CO., 175 West Jackson Blvd., Chicago, Ill., has been incorporated with a capital of $50,000, to manufacture oil products. The incorporators are A. J. Minster and Oscar A. Steffels.

THE STAR SMELTING & REFINING CO., Philadelphia, Pa., care of the Corporation Guarantee & Trust Co., Land Title Bldg., has been incorporated under Delaware laws, with a capital of $10,000, to manufacture refined metal products.

Capital Increases, etc.

THE BAKELITE CORP., 8 West 40th St., New York, N. Y., manufacturer of rubber composition products, has filed notice of increase in capital from $3,100,000 to $5,100,000.

THE REX STEEL STAMPING CO., Joliet, Ill., has filed notice of increase in capital from $40,000 to $100,000.

THE INLAND GLASS CO., Chicago, Ill., has filed notice of increase in capital from $1,500,000 to $2,000,000.

THE HERCULES POWDER CO., Wilmington, Del., has filed notice of increase in capital from $20,000,000 to $40,000,000.

THE MADISON TIRE & RUBBER CO., Buffalo, N. Y., is arranging for a bond issue of $750,000, a portion of the proceeds to be used for general expansion.

THE GENERAL REFRACTORIES CO., Oliver Bldg., Pittsburgh, Pa., has purchased the plants of the Hayes Run Fire Brick Co., Orviston, Pa., and the Pennsylvania Fire Brick Co., Beech Creek, Pa., at the same time increasing its capital to $18,000,000. The acquired properties will be merged with other plants recently secured in this district.

THE JOHN LUCAS CO., 322 Race St., Philadelphia, Pa., manufacturer of paints, varnishes, etc., has arranged for an increase in capital from $1,500,000 to $7,000,000.

Herman Ringel and William C. Ridgway have been appointed receivers for the HOBOKEN PAPER MILL CO., 1 Newark St., Hoboken, N. J. The assets are stated to be $798,000, and liabilities, $759,100.

THE INDEPENDENT OIL & GAS CO., Okmulgee, Okla., is arranging to increase its capital to $10,000,000 for proposed expansion.

Industrial Notes

THE CUTLER-HAMMER MFG. CO., Milwaukee, Wis., in order to give greater attention to business in western New York and the Province of Ontario, has opened a branch office at 358 Ellicott Sq., Buffalo, N. Y. B. A. Hansen, formerly located in the New York office, has been placed in charge.

THE DURIRON CO., INC., Dayton, O., has opened an office at 495 Ellicott Sq., Buffalo, N. Y., to take care of business in that territory. The new office will be in charge of N. E. Philpot, who for the past 2 years has been engineer in charge of the company's Cleveland office.

AUTOMATIC & ELECTRIC FURNACES, LTD., has moved to larger works and offices at 173-175 Farrington Road, London, E C. 1, England. In addition to the Wild-Barfield electric furnaces and laboratory muffles it is introducing new types of muffles for laboratory use, etc.

THE SEMET-SOLVAY CO., Syracuse, N. Y., has been awarded a contract for the construction of a byproduct coke plant of 500 tons daily capacity for the Hoskins Iron & Steel Co., Sydney, New South Wales, Australia. The contract has been awarded as a result of competitive tests on low-grade "zig-zag" Australian coal.

THE WESTON ELECTRICAL INSTRUMENT CO., of Newark, N. J., announces that G. P. Atkinson has opened an office in Atlanta, Ga., for the territory of Georgia, South Carolina and northern Alabama. In addition to Weston instruments, Mr. Atkinson has in charge the sale of other electrical equipment. This company also announces a new line of small portable instruments for use on alternating-current circuits, known as "Weston, Jr." The group comprises wattmeters, voltmeters, ammeters and milliameters.

THE HERCULES POWDER CO., Wilmington, Del., has recently employed the following men at various plants and the research station: Roderick Eskew, Roy S. Hancock, Carl B. Durr, Robert C. Brown, B. I. Stoops, Charles W. Woodrow, H. W. Botts and H. E. Krueger.

Manufacturers' Catalogs

THE BROWN HOISTING MACHINERY CO., Cleveland, O., has issued Catalog L, on Brownhoist drop-forged chain for conveyors and elevators. Copies will be mailed to any reader who is interested.

THE METAL & THERMIT CORP., New York, has issued the fourth edition of its Thermit Locomotive Pamphlet, No. 21, which is of interest to railroad superintendents of motive power, general foremen, blacksmith foremen and Thermit welders. The new pamphlet contains many revisions since the last edition was published, chief among which are instructions for applying important improvements in practice in Thermit welding which have been developed by exhaustive research. The drawings and instructions illustrate and describe the making of Thermit welds in various parts of locomotive frames and other locomotive and railroad equipment, and show improved practice.

THE CENTURY WOOD PRESERVING CO., Pittsburgh, Pa., has issued Bull. 24, on "Treated Ties and Timbers for Industrial Plants."

BALLARD, SPRAGUE & CO., New York, are issuing a new catalog on boiler settings and chimneys. Illustrations of actual installations are given as well as descriptive matter.

THE COLORADO IRON WORKS CO., Denver Colo., in Catalog 32-B discusses the drying of fine materials, with a description of the Lowden patent drier.

THE JEFFREY MFG. CO., Columbus, O., has published three new catalogs: No. 277, "Jeffrey Machinery for Fertilizer Plants," which has 35 pages of illustrations and description and data covering equipments which have a wide range of service in the handling and treatment of materials in the fertilizer and allied industries; No. 258, which illustrates and describes Jeffrey Standard Apron Conveyors in both wood and steel types; and No. 368, which is on Jeffrey Swing Hammer Pulverizers adapted for reducing all kinds of friable materials. This catalog has 42 pages of description, data and other information, together with numerous shop illustrations and installation views showing the wide application of Jeffrey swing hammer pulverizers.

Coming Meetings and Events

AMERICAN CHEMICAL SOCIETY will hold its spring meeting April 3 to 7, 1923, at New Haven, Conn.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting May 3, 4 and 5, 1923, at the Commodore Hotel, New York City.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its winter meeting at Richmond, Va., Dec. 7 to 9.

INTERNATIONAL CHAMBER OF COMMERCE will hold its second general meeting in Rome, Italy, March 19-26, 1923.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, 52 East 41st St., New York City, Nov. 10—American Chemical Society (in charge), Society of Chemical Industry, American Electrochemical Society, Société de Chimie Industrielle, joint meeting. Nov. 17—American Electrochemical Society, regular meeting. Dec. 1—Society of Chemical Industry, regular meeting. Dec. 8—American Chemical Society, regular meeting. Jan. 5—American Chemical Society, regular meeting. Jan. 12—Society of Chemical Industry, Perkin Medal. Feb. 9—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting. March 9—American Chemical Society, Nichols Medal. March 23—Society of Chemical Industry, regular meeting. April 20—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting. May 4—American Chemical Society, regular meeting. May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting. May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.

An Engineer As Ambassador

IN THE appointment of GELASIO CAETANI as Ambassador from Italy to the United States, engineers generally, but particularly mining and metallurgical engineers of the West, will find a new source of pride and gratification. We are no longer unaccustomed to the appointment of engineers to high places in civic affairs, but occasionally a conspicuous example like this excites our admiration. Our Western readers will recall Mr. CAETANI as a man of charming personality and an engineer of exceptional ability who made his mark in ore dressing. In a fine democratic spirit he began at the bottom, following his graduation from the Columbia School of Mines in 1903, and worked his way to recognition through sheer merit. To only a few of his friends was it known that he was the son of the Duke of Sermoneta, and a descendant of a noble Italian house that has been prominent in the national life of Italy for nearly a thousand years.

During the late war Mr. CAETANI served in the Italian army, rose to the rank of Colonel, and gained fame by destroying an Austrian stronghold, the Col di Lana. Since the armistice he has been a prominent figure in Italian affairs, first being elected Mayor of Rome, and subsequently serving as a member of the Chamber of Deputies. It is with this fine heritage that Mr. CAETANI will return to the United States as the Ambassador of his native country; and without disparagement of his eminent predecessors, we feel that he will bring qualities of mind and personality that will add fresh luster to this diplomatic post.

Specifications for A Government Post

IN THE resignation of Dr. STRATTON as director of the Bureau of Standards, the government finds itself confronted with no mean problem—that of discovering a successor technically fitted for the position and financially able to support it.

The Bureau of Standards is probably the greatest physical institution in the world, and in view of its close relation to science and industry it requires a many-sided director. But like most government posts, the salary is not commensurate with the requirements. And while it is a sad commentary on the unwillingness of the government properly to compensate its technical servants, the fact remains that in most of these positions the incumbent must accept honor as a large part of his remuneration.

Imagine a position in industry with the following requirements: (1) A knowledge of industry, from the practical rather than the academic point of view. (2) A broad and profound knowledge of the science of physics. (3) Ability to command the confidence of Congress in order to obtain appropriations for projects of great importance but not particularly spectacular. (4) Administrative experience and executive ability. (5) A quality of social leadership among scientific men and laymen that will command respect for professional standards and scientific workers in the community. And then imagine the salary that would be offered to the happy possessor of these qualifications. It would certainly be several times that established for the director of the Bureau of Standards. And yet these are practically the specifications for the man to fill Dr. STRATTON'S place. But if these were all the task might not be so difficult. We must still add the requirement of a private income sufficient to eke out the salary that Congress has seen fit to establish for the heads of scientific bureaus in Washington.

During the recent war it was not uncommon for men of exceptional ability to abandon their regular vocations and give their services to their country at nominal salaries. Such evidence of patriotism is not unexpected at a time of national crisis, but should not be called for in civil service in times of peace. The dollar-a-year man of war times has returned to his job, but we can almost find his counterpart in the scientific servants of the government today.

Treating Symptoms or Establishing Principles?

IT IS illustrative of our loose habits of thought, or disinclination to think at all, that there was a very favorable popular reaction to the announcement that Congress intended to set up a commission to "get the facts" in the coal industry. Apparently the public had an idea that there was confusion as to the facts. The miners had made various claims as to excessive capacity of coal mines, as to miners being very poorly employed in point of time, and the like. The public was probably assuming that the operators were denying most of the statements. As a matter of fact they were not, and they were making very few statements of their own.

In an industry that employs hundreds of thousands of men and produces hundreds of millions of tons a year there are naturally many facts. The coal commission will probably assemble thousands of facts, perhaps hundreds of thousands if the figures in the tables are counted as facts.

But the whole coal situation may be regarded as an industrial symptom. Here is an industry said to be overdeveloped, overcapitalized and overmanned. The natural laws of trade are expected to correct such conditions. Usually they do; in coal they do not. Surely we all know that this failure is not due to any essential economic quality of coal, differentiating it from iron ore, copper or zinc. If we suspected a difference, we should seek for a great mass of facts not simply in coal

but in all industries to show by comparison how it happens that coal is different.

The great fact in coal is one that requires no commission to find. It is simply that a great labor union has grown up in that industry, one of the results being that the law against restraint of trade is ineffective. For while that law forbids producers to agree with one another to restrict production, it does not forbid coal operators and coal miners from disagreeing with each other, whereby a restriction in production actually occurs.

Herein is involved a definite principle. Is it in accord with public policy to permit workmen to form unions and to permit the unions to restrict production? The tendency of labor unions in the United States is to do this. They do it in the building trades and they have done it with the railroads. These are the most powerful unions in the United States.

What has occurred in coal is merely an industrial symptom resulting from the practice of permitting labor unions to restrict operations. We do not need a great mass of facts about coal in this connection, showing how or to what extent they do it, what their various excuses are and how the money is divided that is thus obtained from the public. We know enough about that already.

What we need is clear thinking as to what principle should be laid down, as a matter of public policy, to govern the relations between employers and employed, whether the work is in coal mining or any other industry. Obviously the coal industry furnishes an excellent opportunity for experimenting in the application of any new principle we may adopt, but if harm is being done by our permitting restraint of trade by employees when we do not permit it by employers, it would be very unfortunate if we should act only when the restraint goes to such outrageous lengths as it has in coal. Public opinion needs to be formed, and for this leadership is usually requisite. Public opinion now holds that workmen will be imposed upon unless they are permitted some latitude. There is only dissatisfaction, and then not a great deal, when the latitude covers arson and murder. Let us adopt the principle, if we find it right, that workmen do need protection and then let us give them the protection freely and properly, instead of letting them commit crimes to protect themselves.

The Chemical Game Of Hide and Seek

A HIGHLY esteemed subscriber writes to ask if we cannot find place for a regular column or department devoted to the results of investigations that are in progress relative to atomic and molecular structures. These problems, he says, "are in a similar position to those of engineers not very long ago. When they desired to build a bridge they first made a model, then loaded it with sandbags, found where it gave way, made these parts stronger, and repeated the process until they finally concluded that the bridge was strong enough. Then, using the model as a criterion, the bridge was built with its stresses and strains computed by a 'cut and try' method. Today they know the characteristics of their materials, and, by simple mathematics, they compute the size of beams and braces when once the load is given." It seems to us he is harking back a considerable time in regard to general engineering methods, but that is not germane to the subject. He wants to see chemists at work, for example, at synthesis, having the facilities of the engineer to compute the units of his structure. So do we.

Our correspondent's appeal for more light is indeed the cry of the chemical world today. We need more study, more definitions and more understanding of chemical forces. Our power, our heat, and water flow, all come from the sun. When we burn coal we are recovering, as the late Professor CIAMICIAN said, the fossil energy of the sun. This is true in that the sun furnished the energy to bring about the endothermic synthesis of cellulose, lignin, gums, etc., in the trees and plants. But chemical energy comes from within the atom.

The Lewis-Langmuir theory is a grand beginning, although progress is slow. Here we have approximately definite geometrical shapes for atoms. The arrangement of protons and electrons is such that there is not complete balance of positive and negative charges on the faces of the atoms, except in those of the inert gases. The pair- and octet-forming drive of electrons in the presence of positive charges accounts for the wandering of electrons from one atom to another to make up or to approximate octets and thus form ions which are held together by electrostatic force, or to cause combined atoms to hold pairs of electrons in common. In this manner molecules are built up. Here is a world of study ahead to enable us to visualize every molecule.

Given this, and we have again a lack of balance on the several faces of the molecule, owing to the preponderance or greater proximity of either positive or negative charges to every face in question. These produce electropositive or electronegative fields of force over the molecular faces, and indicate a reason for the formation of crystals. Granted geometric shapes with definite and similar fields of force on the same face of each, then we can well imagine how the dominant electropositive face will attach itself and cleave to the dominant electronegative face of the molecules of a substance. This would provide for Sir WILLIAM BRAGG'S crystal units made up, as he says, in quartz for instance, of three molecules of SiO_2 arranged in a particular and specific manner. The strongest fields of force would be within the crystal unit with electropositive and electronegative faces joined and held together by electrostatic force. But, so far as we are aware, we have not reached the study and computation of these fields of force as yet.

Within the domain of colloid chemistry the situation is, as usual, rather muddy, foggy, hazy and indefinite. Why is it that some substances form crystals and others do not—so far as we know? Or, granting the above reason for crystal formation, why are some substances amorphous? We are now over in the domain of armchair chemistry, without anything but imagination to help us. We do not know whether amorphous particles are made up of indefinite aggregations of molecules or of crystal units or of both. But suppose the fields of force on the faces of the molecules or crystal units are so evenly balanced that they join "at haphazard," as the saying is; then any electropositive face will join any electronegative face at haphazard, and the resulting aggregates will be irregular. And as soon as the surface of the particle becomes completely electropositive or completely electronegative, then aggregation will cease.

This is mere guessing, and yet it shows how fascinating the field is and how sorely we need additional study and research. Exposition should not be difficult in the end, if we could only get at the facts.

Political Fortunes Of Chemical Industry

ASIDE from its purely political aspects, the recent election has an incidence on chemistry in this country in so far as it determines the attitude of Congress toward our chemical industry. In the Senate we have lost two good friends, T. COLEMAN DU PONT of Delaware and J. S. FRELINGHUYSEN of New Jersey. On the other hand, WILLIAM H. KING of Utah was re-elected and we still have with us Senator MOSES of New Hampshire, both of whom are known to be unsympathetic with the hopes and aspirations of the chemical industry. In the House we have been fortunate in retaining Mr. LONGWORTH, while HERMAN METZ was defeated by OGDEN L. MILLS of New York. The defeat of Mr. VOLSTEAD may have some effect in getting fair treatment for industrial alcohol, because his place as chairman of the Judiciary Committee of the House probably will be taken by Mr. GRAHAM of Pennsylvania, who, we hope, will not be so absorbed in the administration of the prohibition features of the Volstead act that he will fail to recognize the mandate for the encouragement of industrial alcohol.

Intelligent Use of Fire Extinguishers

UNDER the caption "Turning Accident Into Disaster" we commented editorially in our issue of July 19, 1922, on an accident in one of New York's subways in which Pyrene was used to extinguish a fire resulting from an electric short circuit. Current press reports of the accident stated that a large number of passengers had been overcome by fumes of Pyrene and its decomposition products. Knowing something of the chemical properties and physiological effects of carbon tetrachloride, phosgene, chlorine and hydrochloric acid, and accepting as reliable the reports that passengers had been gassed and taken to hospitals for recovery, we drafted an editorial condemning the use of Pyrene in the subway and holding that its use had added to the disastrous consequences of the accident.

Subsequently the official report of investigation by the Transit Commission exonerated Pyrene as a factor in the distress and illness of the passengers. In the light of this report, which was summarized in our issue for Aug. 16, it is obviously incumbent upon us to retract our strictures on the use and effect of Pyrene as far as they pertain to this particular accident. In its investigation the Transit Commission had the benefit of the experience and service of experts from the U. S. Bureau of Mines who are competent authorities on the subject; and if they found that there were no "really serious cases resulting from the effect of possible toxic gases" we are quite willing to accept their verdict.

As a byproduct of the incident we were led to investigate the general use of Pyrene and other forms of carbon tetrachloride fire extinguishers. The results show conclusively that, owing to its poisonous properties, great care should be exercised in its use, since illness and even death may result under some conditions. We are also convinced that, in offering for sale a chemical product of this kind, the manufacturers are in duty bound to protect the public against the consequences of unintelligent use.

We acknowledge error in our interpretation of the subway accident, but feel justified in maintaining the general principles here expressed.

Current Investigations On Fatigue of Metals

ABOUT three years ago a notable investigation into the endurance of metal under rapidly alternating stresses was started by Prof. H. F. MOORE. An enormous amount of work has since been done on a group of steels, some fundamental information of extreme practical value discovered, and at a very low cost—in fact, it amounts to less than one cent on every ton of alloy steel produced during the period. It would be ridiculous to assert that the makers and users of fine steels have not profited to that extent. As a matter of fact, they have gone untaxed, since the cost has been borne by the Engineering Foundation, the General Electric Co. and the University of Illinois.

Within a few weeks the original program will have been completed.

It has established high probability to the belief that metal has a true endurance limit—that is, a unit stress which no matter how often repeated can be successfully resisted. Fortunately for the testing engineer, a slightly higher stress causes failure in less than ten million repetitions, so that these time-consuming tests can then be discontinued.

The investigators have also determined that a very close approximation to the endurance limit may be had by measuring the heat generated in a loaded beam, rapidly rotating, and have devised a simple machine for this purpose. Such a test takes as many hours as formerly required weeks or even months.

An idea of the endurance of a tough steel may even more rapidly be had by assuming it to be 45 per cent of the ultimate tensile strength or 250 times the Brinell hardness.

Designers, manufacturers and users of turbines, high-speed engines, axles or springs will not now have to rely upon factors of safety, or rather factors of ignorance, ranging up to 20. Of course, ripe experience and service records are the ultimate judges of excellence, but such judgments may not be had rapidly. Actual tests are continually needed to pick out the best material from several attractive analyses or heat-treatments. Furthermore, manufacturers of such things as cast steel, drop forgings, wrought aluminum or manganese bronzes and malleable iron are often called upon to make pieces which are subject to alternating stresses. How much do they know about the fitness of the material they furnish for that particular duty? In nearly every case it is less than nothing.

Ultimately, a great many plant laboratories will be equipped with facilities for conducting endurance tests. Purchasers will demand it. But these will require no little money and competent supervision, both of which seem to be rare just now. At the present moment such work can be submitted to Professor MOORE'S department at the University of Illinois and be handled by an experienced test party. It is estimated that reasonably complete data on one lot of metal can be had at a cost of not more than $600—certainly a modest sum compared to the damage resulting from one disastrous failure or, for that matter, to the money already expended by more than one progressive concern in its own laboratory, studying fatigue.

The pioneering work has already been done. American industry doubtless will recognize the economy in making best use of this organization—it can skim the cream, as it were!

Readers' Views and Comments

Impressions Concerning the European Steel Industry

To the Editor of Chemical & Metallurgical Engineering

SIR:—The outstanding impression one receives from a rather extended tour of the north European countries is that business conditions, particularly in iron and steel, are extremely unsettled, and there is a great deal of unemployment.

The output of pig iron in England has increased over 1921 figures, but is still less than half 1919 and 1920 figures. The 1922 output of steel ingots and castings has averaged around 400,000 long tons per month; the average for 1919 was around 700,000, and over 800,000 in 1920. In June, 1922, 115 blast furnaces were operating, against 298 for June, 1920. In June, 1922, 212 open-hearth plants were operating and 497 in June, 1920. Average weekly wages of iron and steel workers are lower now than any time since 1914. The official figure for June, 1922, was £2/16/0 ($12.30) per week, against $22 in June, 1919, and $8.25 in 1913.

Taxes are extremely high in England, many employees and salaried men paying up to 60 per cent of their total income in taxes. This high taxation is blamed for the present stagnation in British industries—the employer will not risk capital or engage in new enterprises and most of them are just waiting for sane business legislation and reasonable taxation.

As is doubtless well known, the British Government has a system of unemployment insurance doles and probably one-quarter of the whole working population is in receipt of these weekly payments. It was stated by the lately deposed government officials that such payments for unemployed were necessary to prevent, possibly, a revolution, but the result has been extremely bad. The worker draws sufficient to keep himself comfortably without working and does not appear anxious to work and earn a somewhat better wage. The employer of labor feels he is unfairly taxed to keep idle these drones and he has no incentive to find more work. He knows the British workmen are too sensible to be gulled by "revolution" talk, but all the same they will take money without working just as long as the government is fool enough to pay. In addition to the unemployed drawing government "doles" there are larger numbers of unemployed not on "dole" who are affected indirectly by the shortage of work in the main industries such as steel, coal and shipbuilding. Co-operative effort by workers and employees, as understood here, is practically unknown and the future looks very dark for many British industries.

The Welsh tin plate mills appear to be the only works running on anything like normal capacity—their output is quite up to previous good years.

From a short visit to France it would appear that there is much less unemployment than in England. A great deal of building and reconstruction work is going on, particularly on the old battle areas. To the writer the one outstanding feature of France was the amount of ground that is being put into cultivation. Contempt and hatred of Germany are still much in evidence but not interfering with their getting down to real work.

Norway appears to be in a transition stage betwee war profits and after-war losses. Their experiment with prohibition were quite farcical. They prohibite wines, so the Spanish and Portuguese prohibite Norwegian dried fish and sardines, practically closin down the Norwegian fishing industry. Then the Nor wegian Government permitted light wines and beer and agreed to take the Spanish and Portuguese win crop in return for the lifting of the embargo on fish.

Just a little example of too much independence!

American products are in considerable demand i Scandinavia, but the unfavorable rate of exchange i preventing much business in American material. Th Fordney tariff has created a very unfavorable impres sion abroad, particularly in those countries which ar large debtors to the United States. The fear is openl expressed that they will be unable to meet these debt until the tariff wall is removed and reasonable trad facilities are given. It is the only way some of thes countries can pay, and if we stop trade we stop pay ments also.

FRANK HODSON.

Electric Furnace Construction Co.,

Galvanic Corrosion on Yacht Sea Call

To the Editor of Chemical & Metallurgical Engineerin

SIR:—In the Oct. 4 number of *Chemical & Metallurgica Engineering*, page 678, and referring to Montreal meet ing of the American Electrochemical Society Henr Howard of Cleveland, Ohio, refers to the disintegratio of the Monel yacht Sea Call. Mr. McKay of the Inter national Nickel Co. explained this by pointing out tha it was a case of electrolytic action—the stem and ster of the yacht and likewise the rivets and bolts were mad of iron.

The general understanding is that the Monel meta showed evidences of depreciation, *and not the iron parts* As Monel metal is quite strongly electronegative to bot cast and wrought iron as well as steel in an electrolyt of sodium chloride solution, the disintegration referre to can scarcely be attributed to electrolytic action.

It will be interesting to hear what Mr. McKay has t say in regard to this.

A. HOUGH.

Summit, N. J.

To the Editor of Chemical & Metallurgical Engineerin

SIR:—If Mr. Hough will refer to the *Engineering New* of Sept. 9, 1915, and to the *Metal Industry* for Novembe 1915, he will find the question of the yacht Sea Call full described by men who made a personal examination o the yacht after she was taken out of the water. Thes reports show clearly that, contrary to Mr. Hough's un derstanding of the situation, the iron and steel showe depreciation, and *not the Monel metal parts.* I agre with Mr. Hough that Monel metal is strongly electro negative to iron in sodium chloride solution. In such cell Monel metal will be the negative pole and the curren in the solution will flow from the iron electrode to tha of Monel metal, disintegrating the iron and protectin the Monel metal, which explains the disintegration re ferred to, contrary to the conclusion drawn by M Hough.

ROBERT J. MCKAY.

New York City.

British Chemical Industries

FROM OUR LONDON CORRESPONDENT

LONDON, Oct. 21, 1922.

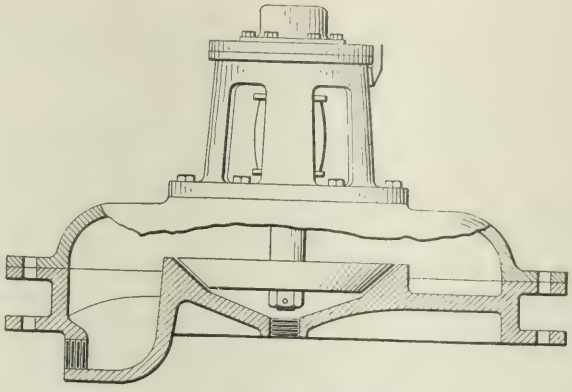
THERE has been a marked improvement in the chemical trade, particularly in heavy chemicals, although there are few changes in price to record. The policy of buying from hand to mouth which has been pursued for so long has probably spent itself and in the near future purchases should be on a larger scale. The recent spectacular rise by which the price of rubber has been doubled is only partly due to the decision to restrict output; similarly, when buyers come forward with more substantial orders, those who have held off too long may also find themselves at a grave disadvantage in regard to certain chemical commodities. The present political upheaval has, if anything, been a bull point, as the policy which a Conservative Government is likely to pursue should benefit British chemical industries at the expense of foreign competitors. This does not necessarily mean that there would be additional tariff legislation and the program would not be influenced materially by the Fordney tariff, the effect of which has already been discounted to some extent, although its precise consequences are not yet clearly realized.

A BRITISH MILL FOR EMULSIFICATION AND DISINTEGRATION

Several articles have recently appeared in the technical press descriptive of the Plauson colloid mill. The Plauson Research Institute has taken out hundreds of patents in connection with the possible application of the principles on which the invention is based, and it would seem that many of the claims formulated are rather in the nature of intelligent anticipation, with actual practical results to follow. Much play has been made with the word colloid, which perhaps may be likened to the diagnosis of "gout" when the routine medico does not quite know what ails his patient. It is therefore refreshing to find a British mill put on the market by the Premier Filterpress Co. working on an entirely different principle, apparently achieving at least equal results and perhaps studiously refraining from the use of the word colloid. The Plauson mill works on the impact principle, while the Premier mill depends on a shearing action in liquid suspension. The object seems of sufficient importance to give a short description in these notes.

DESIGN OF PREMIER MILL AND ITS APPLICATION

Reference to the diagram shows that the mill comprises a conical rotor revolving vertically at 1,000 to 000 r.p.m. in very close proximity to a corresponding achined conical surface in the outer casing, the materials to be treated passing upward between the two urfaces and the whole arrangement bearing a close esemblance to an automobile clutch. The gap between he two surfaces is adjustable by means of a micrometer ead and in practice the clearance may be anything etween 0.003 and 0.025 in., according to the nature of he work being done, without ever permitting the two urfaces to touch. When the mill is working, the material is pumped through in liquid suspension at a suitable ate and, owing to the enormous speed of the rotor, the uspended particles are rapidly torn apart in the passge of the fine film between the conical surfaces. As here are no grinding surfaces, wear and tear are practically eliminated and the power required for the mill itself varies between 2 and 5 hp. when treating 5 to 10 gal. per minute of oils or milk. In practice two liquids normally immiscible become so finely divided that they coalesce and form an emulsion, while solid particles are very minutely disintegrated, the machine being jacketed



THE PREMIER MILL

if necessary, for heating or cooling during operation. As instances of successful application, the regeneration of milk from the dried powder, the manufacture of vanishing cream using about 10 per cent of magnesia, the grinding of ferric oxide and the mixing and incorporation of all kinds of paints, varnishes, enamels, disinfectants, etc., may be mentioned, and the purification of naphthalene, benzene, etc., is also facilitated. Experimental work is continuously being carried out in regard to further new applications, two mills having been installed for that purpose and, as is usual, many initial failures have subsequently developed into real successes by the use of small quantities of additional reagents and by suitable modifications of clearances and other working conditions.

THERE IS LIME AND LIME

Old Buxton lime has held the field for so long that the advent of a serious competitor entailed extensive propaganda. Now that Callow rock lime is making progress we are in the midst of antagonistic advertising by the rival producers on ingenious and even ingenuous lines that remind one of the salesman's comparison between lubricating oils having spherical and triangular molecules respectively. Both firms claim greater chemical reactivity for their product, the Callow interests basing their statements partly on scientific control of the burning operation and on fineness and purity, while the Buxton firms rely largely on reputation and some indefinable "natural properties" possessed by their raw material. Good chemical lime is of considerable importance in the manufacture of bleach and for the alkali, paper, textile, ammonia and other industries, and the booklet issued by the Callow company is instructive in spite of its quite natural bias. Reactivity is presumed to be measured by the rate of reaction with water, and both firms claim that a ton of their lime will go further than a ton of "any other lime." The lesson to be drawn seems that just as for feldspar, standard tests and specifications are needed and also the publication of comparative test results under reliable expert supervision for each particular application in the chemical industry. The fact is that competition has made the producer realize that lime is really a chemical and cannot be placed in the same category as common brick.

European Conditions as I Saw Them*

Comparative Fundamental Conditions in France, Belgium and Germany — Grievances of France as to Her Monetary Status — Analysis of the French Coal Situation, Showing That There Is No Foundation for the German Bitter Complaints Against France's Coal Policy

By J. S. Negru

COMPARING existing conditions in France and Belgium, I am inclined to believe that, taken altogether, France is much better off.

During my trip through these countries I learned of some conditions that are far worse in France than in Belgium, but, in my judgment, these are more than counterbalanced by others which are in her favor. In the unfavorable group of conditions, of course, is the enormous loss in life and devastation of property during the war. But among those things that are of first importance in France's favor are the following:

France is and always will be a self-supporting country, whereas Belgium has always depended and will have to depend on imports for the daily necessities of life and for the raw materials needed to support her old-established industries, such as iron, zinc and glass. France can readily find markets for her products at home, as well as in her extensive colonies, besides being well assured of a large export of goods in the luxury class to practically all the countries of the world. Belgium, on the contrary, can scarcely find markets at home for her products, while her only colony, the Belgian Congo, does not yet absorb appreciable quantities of manufactured goods. As for foreign markets, Belgium has to contend with strong competition from surrounding industrial countries, and this is not lightened by the fact that she must import so much of her raw material.

The great losses of France may be classed as temporary. It may safely be expected that within a very few years she can be reconstructed in population, if I may use such an expression, as well as in devastated property. Her inherent advantages are stable. Belgium, on the contrary, is and will be for a long time to come at the mercy of outside factors that will determine whether she can regain and hold her absolutely necessary foreign market.

These, briefly, are my reasons for saying that, taken altogether, France is much better off than Belgium.

Distinctive Characteristics Between France and Germany

In comparing conditions in France and in Germany, I am led to set down two main points that appeal to me as the fundamental reasons why France is in a far better position than Germany.

First, France has proved in the past that she can be a good loser, and as such, has enjoyed deserved consideration at the hands of the other nations. Everything points to the fact that Germany, too much imbued with a sense of her own importance, was unable to accept the consequences of the war, however hard they may have been, with the result that she is gradually becoming the ward of others.

Second, France is an entity, whereas Germany is merely an artificial aggregation of peoples who have only the language in common. As a result, France was and is one in adversity as well as in prosperity, whereas Germany seems to be on the road to disintegration at the first appearance of adversity.

To the foregoing also may be added the fact that the French demanded revanche (revenge) in all that the word implies, and took it as the best guide of their thoughts and actions. The Germans, on the contrary, are apparently dominated by a spirit of Hass (hatred). Revenge breeds a will to regain superiority by reasoned deeds, however wrong the reasoning may be; hatred breeds bad blood, a kind of animal savagery that prevents clear thinking. "Ich hasse Wilson und mit die Franzosen kein Mitleid" (I hate Wilson and have no pity for the French) was the parting statement given me by Dr. von H. In view of all that is now being written in Germany on the psychology of this and that, it would seem to be timely for them to consider the comparative psychology of revenge and hatred as applied to co-operation among neighboring countries.

Grievances of France as to Her Monetary Status

I had not been long in France before I discovered what one would naturally expect—namely, the grievance of France as to her monetary status. The official figure for reparation expenditures in the devastated regions was put at a little over 80 billion francs in March, 1922. Part of this was advanced by the French Government in monthly installments up to February, 1921, and the remainder was obtained from the sale of shares offered by the devastated industries. Not one pfennig had been paid by Germany for reparation up to March, 1922. Such a statement, coming from many sources and especially from E. Gruner, vice-president of the Comité Central des Houillères de France (Central Committee of French Collieries), was quite evidently a fit subject for conversation with representative Germans. As a consequence, I learned later that although large sums had already been paid by Germany, they had not in the least been used for reparation purposes, but had been expended on the different commissions with their large number of experts and for the maintenance of allied soldiers in Germany.

It is idle for me to pass judgment on the advisability or necessity of having so many allied soldiers in Germany, but with respect to the numerous commissions and their experts I may say that the impression I got of their work is that they are like buckets with screen bottoms, through which huge sums have been poured that might have been used to better advantage.[1]

Another monetary difficulty in France is a consequence of the failure of the Russian Government. Before the war over 20 billion gold francs was invested by the French people in Russian industries, and this sum now looks to be a total loss.

It is not difficult to see, therefore, that the failure

*This is the fourth of a series of articles by Mr. Negru on this subject. The first appeared in the Oct. 18 issue, the second in the Oct. 25 issue, the third in the Nov. 8 issue.

[1]From de C. in France I learned that a very good engineer of "Postes et Télégraphes" was a coal expert in Germany, and on one occasion I dined with a Belgian expert who gave small evidence of fitness for his position.

of both debtors, Germany and Russia, to meet the claims of the French people and the accumulation of huge debts contracted for carrying on the bitter struggle of war are weighing heavily on the French people, and explain somewhat the stand France is taking.[5]

Germany's Bitter Complaint Against the French Coal Policy Unfounded

Germany is making a capital case of her coal situation, and bitter complaints are being made by the intellectuals, as well as the common people, that France is squeezing her out of the much-needed coal which is then used for export purposes. From what I learned I know that this accusation is not warranted but that it is used with great efficacy to keep alive the deep hatred of the German people against the French. I openly expressed this opinion and recorded it in my diary as late as March, 1922, and I shall now endeavor to substantiate it.

According to the stipulations of the peace treaty, it is known that the Saar district is to be worked for a limited number of years by the French as compensation for the devastated French coal mines and that Germany will have to export to France certain tonnages of coal on account of reparations.

Lately Germany has also lost part of the Upper Silesia coal fields. Circumstances did not permit my getting from both sides any impressions about the Upper Silesia coal, so I shall content myself by expressing my personal opinion, gathered in casual conversation, that this loss is more on paper than in reality. Apparently, little of the Upper Silesian coal has been used outside of what is now the lost district. But as this is merely a personal impression, I prefer not to consider it particularly, and I shall dwell only on what I learned from both sides regarding the Saar district and about the export to France.

German Official Coal Figures

Although I am in possession of data and figures gathered during my trip, I shall use instead those presented in an official document of the German Government that came into my possession lately—namely, the "Bericht des Reichskohlenrates über die Kohlenwirtschaft im Jahre 1921," (Situation of the German coal industry in 1921), trusting that conclusions derived from this document will carry more weight.[6]

In 1913, the production of the Saar district was 13,071,000 tons of coal, and that of the Pfalz and Lorraine districts was 4,790,000 tons, respectively 6.8 and 2.5 per cent of the total German coal production for that year. These districts, which in 1913 had a total production of 17,861,000 tons, or 9.3 per cent of the total German coal production, are now in French hands. During the same year the production of coal in what is now the French devastated region was 18,662,000 tons.

In 1921, the Saar, Pfalz and Lorraine districts produced 9,574,000 tons of coal, and the French devastated district 5,365,000 tons, a total of 14,939,000 tons, as against 18,662,000 tons in 1913. Thus, France still has a deficit of 3,723,000 tons with the Saar, Pfalz and Lorraine districts included.

In 1913, the total French production was 40,278,000 tons of coal,[7] of which 21,616,000 was in the non-devastated area. In 1921, the total production was 27,516,000 tons, of which 22,151,000 tons was in the non-devastated area. This gives an excess of 535,000 tons in 1921 over the 1913 production in the non-devastated area.

The French import and export of coal for 1913 and 1921 were as follows:

Year	Import Tons	Export Tons
1913	23,889,000	1,511,000
1921	23,132,000[8]	2,360,000

In 1913, the amount of coal in France was: 40,278,000 tons mined in France plus 23,889,000 tons imported minus 1,511,000 tons exported—i.e., a net total of 62,656,000 tons. In 1921, the amount of coal in France was: 22,151,000 tons mined in the non-devastated area plus 5,365,000 tons mined in the devastated area plus 9,575,000 tons from the Saar, Pfalz and Lorraine districts plus 23,132,000 tons imported minus 2,360,000 tons exported—i.e., a net total of 57,863,000 tons, as compared with the net total of 62,656,000 tons in 1913, a difference of 4,793,000 tons.[9]

These figures show clearly that the 1921 export of 849,000 tons in excess of that of 1913, the decrease in import of 757,000 tons in 1921 as compared with 1913 and the deficiency of 4,793,000 tons between the French total coal in 1913 and 1921 do not warrant in the least the bitter accusation of the Germans that their coal industry is crippled by the French, who, they contend, use all of the coal imported from Germany for export purposes only, while Germany is forced to buy English coal with her depreciated marks.

It might be well to give here additional figures showing German coal production, import and export, for 1913 and 1921:

Year	Production Tons	Import Tons	Export Tons
1913	209,467,000	16,257,000	45,986,000
1921	163,286,000[10]	3,223,000	26,903,000[11]

Nor do these figures show that the German coal industry is thoroughly crippled by the French, for the import in 1921 was less than 20 per cent of that in 1913, and the reduction in the total amount of coal mined was not due solely to the loss of a maximum of 17,861,000 tons from the Saar, Pfalz and Lorraine districts (1913 production), but to the diminished working capacity of the miners. Similarly, the 26,903,000 tons export for 1921, of which less than 70 per cent goes to the Entente for war reparation, is not in the least as discouraging as the Germans make out, when compared with the export of 45,986,000 tons in 1913.

While I was still in Germany I was aware of the existence of these figures, and I used them in conversation with industrial leaders. Some of those with whom I spoke contended that quality as well as quantity of coal had to be taken into consideration. Granting this, I wish to add that, from personal experience, I know

[5] In confirmation of these impressions that I gained in April, I may cite the following enumeration of conditions by Lord Henry Bentinck, published in the London *Times* for Aug. 1, 1922:

"1. Great Britain and America together are claiming from France a far larger sum than France can ever hope to receive from Germany.

"2. While Great Britain has secured, as spoils of victory, large accessions of territory and the removal of the menace of the German navy and the competition of her commercial fleet, France has not yet received any substantial payment for the restoration of her devastated areas.

"3. While France's claim is a just one, Great Britain's claim for payment of pensions and allowances, while being of doubtful justice and questionable morality, has contributed to the present impasse by piling on Germany a burden of debt impossible to discharge."

[6] The document is dated April 1, 1922.

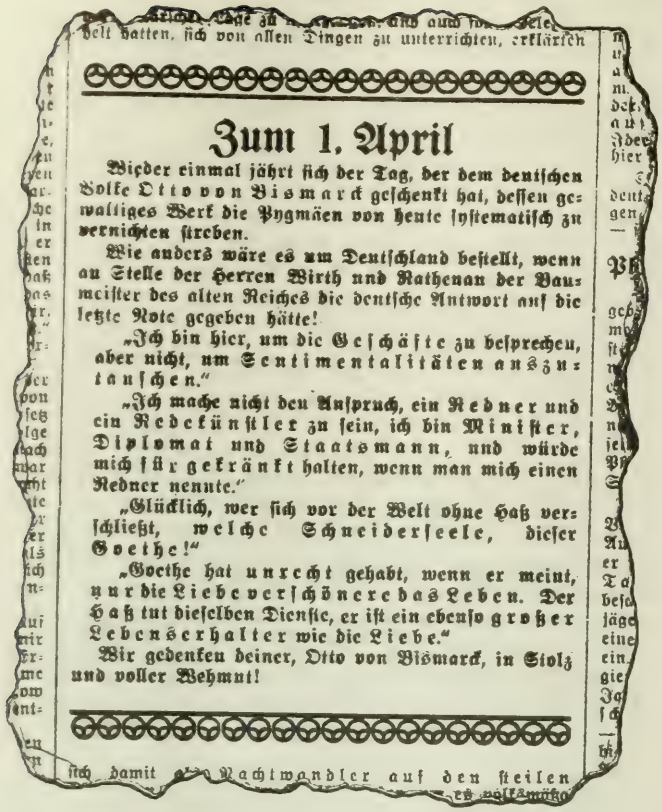
[7] All the figures of coal tonnage refer to the sum of the separate items of coal, coke and lignite, calculated on a coal basis.

[8] This includes also the total amount imported from Germany on account of war reparations.

[9] I have learned from authoritative sources that the present French demand for coal is practically the same as before the war, even with her western industries not yet fully reconstructed.

[10] This does not include the Saar, Pfalz and Lorraine districts.

[11] This includes also the total amount exported to the Entente on account of war reparations.



Zum 1. April

Wieder einmal jährt sich der Tag, der dem deutschen Volke Otto von Bismarck geschenkt hat, dessen gewaltiges Werk die Pygmäen von heute systematisch zu vernichten streben.

Wie anders wäre es um Deutschland bestellt, wenn an Stelle der Herren Wirth und Rathenau der Baumeister des alten Reiches die deutsche Antwort auf die letzte Note gegeben hätte!

„Ich bin hier, um die Geschäfte zu besprechen, aber nicht, um Sentimentalitäten auszutauschen."

„Ich mache nicht den Anspruch, ein Redner und ein Redekünstler zu sein, ich bin Minister, Diplomat und Staatsmann, und würde mich für gekränkt halten, wenn man mich einen Redner nennte."

„Glücklich, wer sich vor der Welt ohne Haß verschließt, welche Schneiderseele, dieser Goethe!"

„Goethe hat unrecht gehabt, wenn er meint, nur die Liebe verschönere das Leben. Der Haß tut dieselben Dienste, er ist ein ebenso großer Lebenserhalter wie die Liebe."

Wir gedenken deiner, Otto von Bismarck, in Stolz und voller Wehmut!

TRANSLATION

For the First of April

Once again has arrived the date when Otto von Bismarck was given to the German people, the man whose gigantic work the pygmies of today try systematically to destroy.

How different it would have been for Germany if the answer to the last note had been framed by the builder of the old empire, and not by Wirth and Rathenau.

"I am here to talk business, and not to discuss sentimentalities."

"I do not pretend to be an orator nor a master of oratory; I am a minister, diplomat and statesman, and I would feel injured were I to be called an orator."

"Happy are those who have lived without hatred. What a simpleton this Goethe!"

"Goethe was wrong when he stated that love alone beautifies life. Hate does the same thing. It stimulates life just as strongly as love does."

We remember you, Otto von Bismarck, with pride and deep sorrow.

that the quality of coal exported from Germany in prewar time was the same as that of 1921.

Only those who have witnessed the exalted spirit of hatred of the Germans against the French on account of their wrong conception of the coal situation can realize how well it would be for the Germans to study the above-mentioned official German report and reason out the actual conditions. This, and similar reports, would do much to counteract and perhaps stop the hate-breeding propaganda carried on through German papers.[12]

Other articles by Mr. Negru on this subject will appear in subsequent issues.

[12] The official coal report is dated April 1. On the same date, which is the anniversary of Bismarck's birth, the Berlin weekly newspaper *Die Gesellschaft* published in heavy black letters the item reproduced herewith, the quotations being selections from Bismarck's utterances.

Russian Chemical Industries

THE FIRST nitric acid factory in Russia has recently been opened in a small town near the Black Sea. The Russian Government has offered important concessions to foreign capital for the establishment of three such factories. In the meantime Russia has gone ahead with this factory, known as the "Yousovsky," which occupies 21½ acres near the Novo-Snolianikev mine, formerly owned by the Novorossiisk company. The liquid ammonia process is used, with a platinum catalyst in the oxidation reaction. The yield is extremely satisfactory, as the following table shows. The yield at the Yousovsky factory is here compared with those of well-known foreign factories:

Process	Percentage Yield	Quality of Ammonia in Kg. Used Per Oz. of Platinum Per Day
Ostwald	85	14.7
Amer. Cyanamid	90.92	22.65
Bureau of Mines	90.91	27.2
Yousovsky Factory	93.97	17.27

PHOSPHATE WORKS IN RUSSIA

Two superphosphate works, one at Kineshma and the other at Nijni, are at present at a standstill owing to lack of capital and the necessity for re-equipment. The Briansk factory, although working, is in a not much better condition. On the other hand, the exploitation of the huge rediscovered phosphate deposits in the Province of Viatka and near Moscow has begun, but the work is still on a small scale. A proposal was made to import phosphates, but it has been decided first to investigate fully the possibility of home production. Large stocks of phosphates exist, but a market cannot be found for them owing to the high cost at which they are produced and to the low purchasing capacity of the peasants. A commission has been appointed to see whether these stocks cannot be sold (*a*) through a company; (*b*) by direct credits to the peasants; (*c*) by lowering the price of phosphate. If these measures are not successful, phosphates will have to be imported from abroad.

Extensive deposits of kaolin, graphite and manganese have been discovered in the Province of Odessa; work on these has already begun. Large quantities of bismuth have been discovered in the Trans-Baikal Province, on the territory of the Far Eastern Republic.

SUGAR AND SOAP INDUSTRIES

For lack of necessary and modern equipment the sugar and soap factories in Russia are operating on very low production. The price of sugar is very high. Soap sells for from two to three times the price in the United States.

SANTONINE IN TASHKENT RUSSIA

The santonine factory in Tchikment, in the Province of Tashkent, was nationalized in 1918 and placed under the control of the Supreme Council of National Economy. The latter body had the factory put into shape and operation in 1920, with the result that now 100,000 poods (3,600,000 lb.) of raw materials is worked annually and 5,000 kg. of pure santonine is produced.

The santonine plants (*Artimisia citæ*) grow in the Tashkent district of Russia. Over 1,000,000 acres are devoted to the growth of this plant. An acre yields about 60 kg. of the plant, which is brought over for processing to the Tchikment factory. Before the war santonine was chiefly purchased from Merck in Germany.

Fireclay Refractories

Outline of Manufacturing Operations at the Laclede-Christy Clay Products Co., St. Louis—Dry Press and Stiff-Mud Process Fireclay Brick—Special Shapes—Glass House Refractories—Washed Pot Clay

By Alan G. Wikoff

IT IS PROBABLE that the fireclay refractory industry in the United States dates from 1812, when a firebrick plant was erected in New Jersey, although he exact location of this first plant is uncertain. With he increasing industrial demand for materials more efractory than common brick, the industry developed apidly, deposits of suitable clay being abundant in any localities. By 1842 the industry had progressed s far west as St. Louis, where 2 years later the Laclede 'ire Brick Manufacturing Co. was established. In 857 the Christy Fire Clay Co. was founded, and the ombination of these two firms in 1907 formed the resent Laclede-Christy Clay Products Co.

Owning 240 acres of clay mines right in the heart f the famous Cheltenham clay district, the company is ssured of a constant supply of this essential raw mate- ial. The two main plants are located within the city mits of St. Louis, the larger of these, known as the aclede plant, being located on Manchester Ave. south f Forest Park. The Christy plant is about 2 miles rther south on Kingshighway Boulevard.

Practically every variety of fireclay article is made these plants. The refractories line is particularly mplete, including six grades of firebrick adapted to eet the different conditions of heat, abrasion and flux- g action encountered in industrial furnaces; chemical ick and acid tower packing rings; special shapes and le for boilers, stokers and furnaces; glass house re- actories. In addition clays are prepared for use in number of other industries, such as the manufacture f glass house pots, lead pencils, crucibles, oilcloth and per filler. Sewer tile, drain tile and related products e also made from fireclay, a considerable portion of e Laclede plant being devoted to their manufacture. he total daily capacity of the plants is 700 tons.

In spite of the great variety of products, the number different manufacturing methods is not large, so that rather brief outline will serve to indicate the opera- ons at these plants.

Laclede Plant

Three plants comprise the Laclede group, numbered follows: 1, brick and tile; 2, sewer pipe; 3, refrac- ries.

Dry Press Process Brick

Two brands are made by the dry press process, the ss refractory having a fusion point of Seger cone 29 us, or about 3,100 deg. F., while the other melts at ne 32 plus, or about 3,200 deg. F. While the clay ixtures differ, the process remains the same for both ades.

Cheltenham plastic clay forms the raw material for the s refractory grade. It is brought from the mines st back of the plant on a narrow-gage high line so at the clay can be dumped through hoppers into orage bins. When ready for use, the clay is shoveled to a measuring car having adjustable vertical parti- ons which determine the proportions of raw and rnt clay, or grog, in the mixture. The mix is dropped rough a chute onto an apron feeder which supplies a conveyor running to the dry pans, where the material is ground. It is then transferred to storage bins on an upper floor by means of a bucket elevator.

Mixtures for the more highly refractory grade contain, in addition to the plastic clay, raw and burnt semi-flint clay from mines owned by the company in northern Missouri.

Chutes from the storage bins deliver into agitators which are simply cylindrical wooden tanks provided with a mechanical stirring device. These serve to maintain a steady flow of material to the three Boyd dry presses on the floor below. The tremendous pressure applied forms brick so firm that they will stand almost any amount of handling, even before drying.

Waste Heat Driers

For drying, the brick are carefully arranged on double deck cars holding about 540 9-in. brick. The driers consist of a series of parallel tunnels through which the cars are pulled by an electric crab. The motion is not continuous, as the cars must remain in the drier for about 2 days. At regular intervals cars of dried brick are drawn, a corresponding number of cars of green brick being run in at the other side of the tunnel so that it is always full.

Heat from kilns which are cooling is supplied to the driers by a powerful blower so as to maintain a temperature of about 210 deg. F. at the exit end. A Bristol recording thermometer gives a permanent record of drier conditions. Every 2 months anemometer readings are taken to make sure that the flues leading from the kilns to the driers are open and free from obstruction.

There is a space in front of the driers so that the brick can cool off before going into the kiln. In case no kiln is ready the cars can still be drawn on schedule and held there. Fig. 1 shows several cars of brick ready for the kiln and also the electric crab which is used to pull the cars. This runs on a track laid at right angles to the drier tracks. Transfer cars also use this track in distributing cars of brick to the tracks in the kiln yard.

At first sight it would seem possible to conserve heat by transferring the brick immediately from the driers to the kilns, but as the brick must be set by hand, they would be too hot to handle. Further, about 2 days is

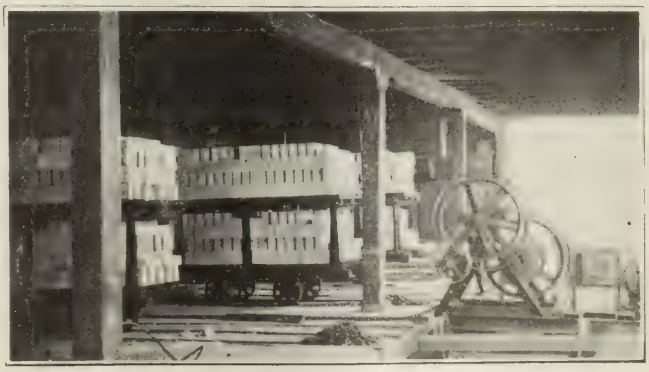


FIG. 1—DISCHARGE END OF DRIERS

FIG. 2—SETTING RECTANGULAR KILN

required to set a kiln, so that most of the heat would be lost anyway before the kiln could be fired.

Burning

Refractories are all burned at this plant in down-draft periodic kilns of either the round or rectangular type, there being seventeen kilns at the brick and tile plant and nine at the refractories plant. The capacity varies from 240 to 350 tons. As a 9-in. brick weighs about 7 lb., the latter figure is equivalent to about 100,000 9-in. brick.

In setting a kiln, unnecessary handling is eliminated by running the cars of dried brick right into the kiln, as shown in Fig. 2, which also illustrates the method of setting a rectangular kiln. Brick in the lower part of the setting are arranged according to a definite plan which will give the most uniform burn throughout the kiln. Tile and special shapes are placed in the upper part.

The burning schedule is followed by the indications of a Price pyrometer. A recording instrument of the same make serves as a check on the burners and also gives a permanent record. Kilns are finished at about 2,350 deg. F., the exact time being determined by drawing trial pieces from the kiln and observing Seger cones.

Kiln turnover is from 14 to 16 days, as follows: Setting, 2; burning, 5 to 6; cooling, 5 to 6; drawing, 2.

Stiff Mud Process Brick

As in the case of the process just described, two brands are made by the stiff mud process. Here again the only difference is in the composition of the mixtures, the more refractory grade containing flint clay as well as plastic clay.

Ground mixtures are fed from the storage bins to a poidometer which controls the delivery of clay and water to a pug mill in the exact proportions necessary to form a mud of the desired consistency. The clay is then worked in a vertical auger machine, discharging in the form of a continuous column from which the brick are formed by a wire cutter. The rough brick are then put through represses to insure true dimensions and a clean-cut finish. The brand is also stamped into the brick during this operation.

Subsequent operations of drying and burning are similar to those for dry press brick.

Special Shapes

Of particular interest is the recent development of machine molding for certain special shapes which have hitherto been molded by hand. Of necessity the designs must be small, fairly simple and in sufficient demand to warrant the expense of preparing special dies. Pourin nozzles for use in steel mills are being made this wa successfully.

Mixtures for special shapes are brought to a worl able consistency with water in an auger machine, th proportions of water and clay being regulated by poidometer. Numerous mixes have been developed t meet the conditions to which a particular shape will b subjected in service. Whenever possible wooden mol are used and the pieces are set on steam-heated woode drying floors until ready to go to the kiln. Their di position in the kiln has already been indicated.

Christy Plant

While brick are also made at the Christy plant, th processes are so similar to those already outlined tha further consideration is unnecessary. Features of pa ticular interest at this plant are the manufacture glass house refractories, preparation of clays for speci uses, and the ceramic laboratory. Fig. 3 is a gener view of this plant.

Glass House Refractories

Owing to the unusually severe service conditions, th manufacture of refractories for use in the glass indu try presents many difficult problems. For exampl modern continuous tanks are operated at about 1,5 deg. C., or 2,750 deg. F., and the refractory bloc which form the bottom and sides of such furnaces mu resist the fluxing and wearing action of molten gla at this temperature. In addition, the blocks must n check or crack with changes in temperature and shou be good non-conductors of heat. The requirements f glass pots are even more exacting. The Cheltenha deposit is one of a very few in the United States whi yields clay suitable for these purposes.

Tank blocks are carried in stock in sizes varyi from 12x12x18 in. to 12x24x36 in., and the care whi must be exercised to obtain uniformity of compositio drying and burning in pieces of such size can readi be appreciated.

Pot clay purified by washing is used in the prepar tion of tank blocks of the flux grade, the grain size a proportion of raw to burnt clay being carefully adjust to give the desired properties to the finished block. T mixture is tempered with water in wet pans to th proper consistency, aged, pugged and worked into th molds by hand. The blocks are permitted to dry the floor very slowly in order to prevent cracking. Aft drying, the blocks are trued by the action of eme wheels in a machine made by the Niles Tool Machine Co. The emery wheels themselves wear very rapid and have to be trued about once a day.

The blocks are burned in round down-draft period

FIG. 3—GENERAL VIEW OF CHRISTY PLANT

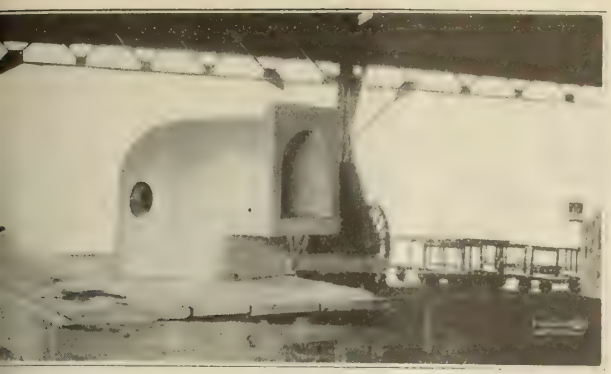

FIG. 4—BOOT FOR GLASS FURNACE

ıs, the blocks being set in the center surrounded by -ft. ring of washed clay blocks.

Many other interesting shapes are made for the glass ustry, such as gathering rings 4 ft. in diameter, ter legs up to 8 ft. in length and boots as shown in . 4. Nor are the products of this plant limited en- ly to glass house materials. Figs. 5 and 6 are ical of the wide range of complicated shapes. The er is particularly interesting because of the core ch in the finished block passes completely around the tral circular opening. The photograph shows only right-hand portion of a complete block split through center.

Washed Pot Clay

he use of washed pot clay in the manufacture of k blocks has already been referred to. This is also pared for sale in various forms. In wooden tanks ided with agitators, a slip is prepared by beating selected pot clay with water. The slip passes ugh a screen into a trough which leads from the agitators to six wooden settling tanks. The trough a chain drag conveyor to prevent settling in transit. r the clay has settled in the tanks, the clean water rawn off and the thick clay soup pumped through a ery of eight Johnson filter presses. These have a city of 15 tons of clay and it is possible to fill them times per day, giving a daily capacity of 60 tons. cakes are dumped to a conveyor which feeds a pug The washed clay emerges from this in the form continuous column which is cut up into blocks hing about 23 lb. when dry. Some of the blocks alcined and ground to form grog. The clay may be as blocks or ground, either dried or calcined accord- o the requirements of the purchaser.

Bagging Clays

ny of the prepared clays are shipped in a finely d state. The material is fed through an automatic weighing hopper into bags which pass on a very short conveyor belt to a stitching machine made by the Union Special Machine Co. The bags proceed on a gravity roller conveyor to another conveyor which delivers them right to the car. One man at the machine and one man at the car can handle 2,000 100-lb. sacks of clay per day in this way.

FIG. 5—TYPICAL SPECIAL SHAPE

Ceramic Laboratory

The laboratory is located at the Christy plant but it serves Laclede plant as well. It is up to date in every respect and is a vital department of this company. Here experiments are conducted for developing new mixtures and products for almost every conceivable refractory use.

In addition to new work, a careful check is kept on the standards of quality of each product. This entails periodical control tests. The various products and mixes have been developed to meet particular requirements and it is to assure the necessary characteristics of each that the control tests are made. The most important of these are: chemical analysis (ratio of silica-alumina content to flux); spalling (action under sudden changes of temperature); fusion or melting point; reheat (linear changes after having been fired at high temperatures); load (compression under load at high temperature); resistance to slagging action.

FIG. 6—COMPLICATED SHAPE WITH CORE

For assistance in obtaining data for this article, the writer is particularly indebted to Richard D. Hatton, vice-president and general manager, W. F. Godejohn, industrial engineer, and John B. Lyons, superintendent of the Christy plant.

The Ural Platinum Mines

The provisioning and financial condition of the Ural platinum mines have considerably improved since the end of July, which in turn favorably affected production. Up to July 1 production was considerably below the program, whereas the July program was exceeded by about 30 per cent. The estimated output of private prospectors was realized only to the extent of 28.45 per cent up to July 1, due to shortage of supplies for paying the prospectors, which was also the cause of thefts of metal. The mines are provided with fuel to the end of the fiscal year.

The output of platinum and the incidental production of gold in all the Ural mines from Jan. 1 to July 15 amounted to 700 lb. of the former and 158 lb. of the latter metal; also 111 grains of iridium were recovered. Apart from this, 87 lb. of platinum was purchased from outsiders.

Use of Bleaching Powder for Sweetening Gasoline

By H. W. Young* and A. W. Peake†

Development of Process at the Midwest Refining Co.'s Plant at Salt Creek, Wyo., for Treating Natural Gas Gasoline or Product From Stills — Description of Plant and Operating Practice

GASOLINE is considered sweet or sour, depending on whether it is negative or positive to the doctor test.[1] A positive doctor test indicates the presence of sulphur compounds which may be objectionable in themselves, or may, in decomposing, impart to the gasoline certain undesirable properties. The principal claim to superiority for sweet gasoline is that it is more stable in storage, showing less tendency toward the development of a yellow color and an objectionable odor.

During, and for some time following, the world war, the demand for gasoline was so great that much was marketed which would not now pass inspection. With the return of conditions more nearly approaching normal, competition among marketing concerns again became a factor. This competition led to a demand for sweet gasoline which increased to such a degree that many marketing companies would not accept sour gasoline from the refiners. In the spring of 1921 the sales department of the Midwest Refining Co. issued instructions that it would be necessary to sweeten the blend produced at the Salt Creek gasoline plant, a natural gas gasoline plant owned by that company and located in the Salt Creek Oil Field, Natrona County, Wyoming.

Usual Methods of Sweetening

In order to bring out more clearly the difficulties involved in meeting this situation, a review of the established methods of sweetening gasoline and of the conditions surrounding the production and shipping of the blend is presented.

The usual methods of sweetening involve the use of sulphuric acid, caustic soda, litharge and sulphur. Local conditions frequently render the use of certain of the reagents unnecessary. The application of doctor solution discolors the gasoline. This discoloration may be removed in part by a water wash, but usually sulphur is added, followed by a water wash. An immense volume of water is ordinarily used.

Natural gas gasoline is produced at the Salt Creek plant by the compression method. This is blended in about a 50:50 ratio with naphtha topped from crude petroleum at the plant. The blend is weathered to the desired vapor pressure then pumped to the refinery at Casper, 42 miles away.

The local supply of water in the Salt Creek field is an uncertain quantity. During times of protracted drought —a not unusual condition in central Wyoming—very little, if any, water can be drawn from the gravels in the creek beds. The supply from wells is inadequate and water pumped from the North Platte River at Casper is too expensive for use in large quantities.

Three conditions made the usual methods of sweeten ing unsuitable for use at Salt Creek:

(1) The water supply was inadequate to permit suffi cient washing of the treated blend.

(2) The high initial cost of such a plant couple with the high cost of attendance and of transportatic of supplies.

(3) Steam stilling the treated blend to remove c color would involve heavy expense for equipment ar would be a serious drain on the already meager wat supply.

It was imperative therefore to develop, if possibl an inexpensive method which would not discolor t blend and which would involve a minimum of washin

Preliminary Tests

In view of the fact that sourness is ordinarily attri uted to the presence of certain easily decomposal sulphur compounds, the problem naturally resolv itself into two lines of investigation:

(1) The precipitation and removal of the sulphur insoluble sulphide.

(2) The oxidation of the sulphur to a more sta form.

A series of tests was made with reagents, which, the presence of soluble sulphides, form insoluble s phides. Ferrous sulphate did not prove of any ben whatever. Copper sulphate sweetened momentarily, It was of no permanent benefit. Soluble salts of sil r sweetened permanently, as did also mercury and m curic oxide. This is strong evidence that the sulpl r is in the form of mercaptans. Additional proof of t s view was developed in later investigations.

While the results recorded above were interest g from a scientific standpoint, they were of no pract l value. The first oxidizing substance used was brom e water, which proved an excellent sweetening ag t. Iodine likewise gave good results. Freshly prepa d chlorine water proved excellent for the purpose. 'e high cost of bromine and iodine prohibited their se on a commercial scale, but it was certain that chlo e could be obtained at a reasonably low cost. The bl d was not discolored during treatment and was practic ly freed from chlorine and chlorides by relatively l le washing. To sum up, the work to this time had s closed the essentials of a process which apparently et all requirements for use under local conditions.

However, since chlorine is an extremely active e ment, there naturally arose a question as to the poss il ity of reactions between it and the liquid hydrocarb during treatment. Such reactions would incr s unduly the consumption of chlorine and might y products deleterious to the blend.

The literature relative to the formation of subs u tion products by reaction of chlorine with liquid pa f fine hydrocarbons is meager and conflicting. In ge a it may be said that these reactions are favored by g temperature, light and catalytic agents. Since h

*Research engineer, gas department, Midwest Refining Co., Salt Creek, Wyo.

†Chief engineer of field division, Midwest Refining Co., Casper, Wyo.

[1] Tech. Paper 214, U. S. Bureau of Mines, covers all details of the doctor test.

proposed treatment would take place at low temperature, in the dark and with no catalytic agent present, it was considered unlikely that such reactions would occur.

Hydrocarbons of the olefine and acetylene series react readily with chlorine, forming addition products. The low consumption of chlorine indicated that hydrocarbons of these types were either absent from the blend or present only in very small amounts.

Chlorine contained in steel cylinders could scarcely be considered on account of high transportation costs. It was thought that by electrolyzing a solution of sodium chloride in a suitably designed cell chlorine could be produced rather cheaply. In addition, if desired, the chlorine could be absorbed in the caustic solution produced in the cell, forming sodium hypochlorite. This would make possible the use of an alkaline solution which would considerably reduce the outlay for specially constructed equipment.

Dr. Loy, chief chemist of the Midwest Refinery at Casper, suggested the use of bleaching powder as a substitute for chlorine or sodium hypochlorite. Bottle tests proved this a good sweetening agent.

Small-Scale Plant

A small-scale plant was built to determine as nearly as possible the conditions under which plant operation should be conducted. Two 5-ft. towers made from 6-in. pipe were about half filled with broken sewer tile, which served as baffling. The first tower was filled to about two-thirds capacity with a solution of bleaching powder in water, the second was filled to like capacity with water. The blend, weathered to about 35 lb. vapor pressure, was introduced at the bottom of the treating tower, passed upward through the solution to the top of this tower, then downward through a small pipe to the bottom of the washing tower. It passed upward through the wash water, then to a storage tower, where it was measured. The pressure drop in the treating system was kept as small as possible. In all tests made with this equipment ½ lb. of bleaching powder was used.

Several tests were made with the apparatus as described, in each of which ½ lb. of powder sweetened about 100 gal. of blend. This was considerably below the efficiency which bottle tests had shown should be obtained. It was decided to try the effect of aërating the solution. A small tower was connected with the bottom of the treating tower, with connections so arranged that a portion of the solution could be drawn off and aërated, then returned by air pressure to the tower. Several tests were made in which, by repeated aëration of solution, each half pound of powder sweetened about 166 gal. of blend.

Tests made on the spent solution showed that considerable available chlorine still remained. There seemed to be a minimum strength of solution below which sweetening would not take place in this apparatus. A second half pound was added to the spent solution and the test repeated, the volume sweetened being 225 gal. A third test gave results checking the second. This test was repeated a number of times, and in every case ½ lb. of powder, with an available chlorine content of about 30 per cent, sweetened 225 gal. of blend. This is at the rate of 2.22 lb. per 1,000 gal., or 0.0933 lb. per barrel.

These results were considered sufficiently encouraging to warrant proceeding with the design and construction of a plant capable of treating the entire volume of blend being produced.

Tests made on the spent solution revealed the presence of sulphate. In one bottle test and one test with the small-scale plant, distilled water was used in making up the solution and the sulphate determined by precipitation with barium chloride. The weight of sulphur oxidized to the sulphate condition per 1,000 gal. of blend treated was found in each test to be 2 grams.

Frequent mention is made in the patent literature of the use of chlorine and hypochlorites for decolorizing and "purifying" petroleum products. The only specific mention so far encountered of the use of bleaching powder for sweetening gasoline is contained in the U. S. Patent 723,368. This patent was issued March 24, 1903, and expired 17 years later. Excerpts appear in "Gasoline and Other Motor Fuels," by Ellis and Meigs, p. 106 *et seq.* This book appeared several weeks after the plant at Salt Creek was placed in commission. The process described in the above-mentioned patent is unnecessarily complicated, and, so far as known, was never employed on a commercial scale.

Large-Scale Plant

Some modifications were made in the plant as originally constructed, during the first few weeks of operation. The following description applies to the plant which has been in service for about 14 months.

The building housing the treating plant is steam heated and thoroughly ventilated. This building is divided into two rooms, the pump and control room, and the treating room proper. In the treating room are five towers, placed in a row. An open top tower of 500-gal. capacity, in which the solution is aërated, is placed next to the pump room. The remaining four are, in order, for weathering, treating, washing and settling. These towers are 6½ ft. in diameter and 20 ft. in height, with dished heads, designed to operate at 50 lb. pressure. These were not especially designed for the purpose, being "daily run" towers which were no longer needed. Standard wrought-iron pipe couplings were welded on for gage glass fittings, intake, discharge and such other connections as were desired.

In the pump room are located two steam-driven duplex pumps, each 5¼x3½x5 in., one for circulating solution, the other for circulating wash water. There is also a box in which fresh charges of bleaching powder are dissolved; a cabinet contains all chemicals and apparatus necessary for determining the available chlorine in the solution and for making doctor tests on the treated product.

The four large towers are provided with one set of relief valves connected to a common header which carries the weathered gas from the building. As an additional precaution each tower is provided with an independent relief valve, which is set to operate at slightly higher pressure. A pressure gage board is located in the pump room and a separate pressure gage is placed on the side of each tower. Each tower is provided with a complete set of gage glasses.

The blend, received from the plant accumulators, passes through a valve into the weathering tower, where the vapor pressure is reduced to about 42 lb., which is sufficient to force the blend through the system and to storage. From the bottom of this tower the blend passes through a knothole mixer (Fig. 1) and enters the treating tower near the bottom.[2] The treating solution is pumped into the mixer. During the brief interval of

[2]This knothole mixer is extensively employed at the Midwest Refinery at Casper.

intimate contact practically all the treating takes place. The blend entering the treating tower rises through about 5 ft. of solution, then continues slowly upward to the outlet, which is about 18 in. from the top of the tower. It then passes downward through a 4-in. pipe to near the bottom of the washing tower, in which it rises through about 8 ft. of glazed tile baffling submerged in water. It continues upward to the outlet about 18 in. from the top of this tower, then downward to near the bottom of the settling tower, in which it rises to the outlet about 8 ft. from the bottom, thence to storage. Any water or emulsion which collects in this tower is drawn off.

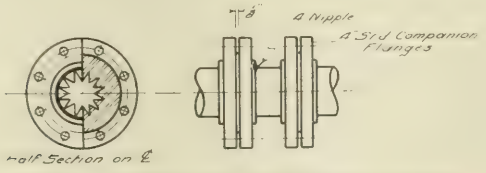

FIG. 1—DETAIL OF KNOTHOLE MIXER

The solution returning from the treating tower may be run into the 500-gal. tower, where it is aërated by splashing over a baffle, or it may be drawn directly into the pump. The latter is called the "closed circuit" plan. The average volume of solution maintained in the system is about 2,000 gal. The weight of bleaching powder in solution varies from 50 to 75 lb.

The wash water is drawn from a tank outside the building and introduced into the washing tower through two pipes which discharge it about 5 ft. below the top of the tower. The water returns to the flow tank through a pipe connected near the bottom of the tower. As the plant was originally designed the purpose of the outside tank was to provide a collecting place for emulsion and to furnish additional storage capacity for wash water. Experience has shown that little emulsion ever collects there. In cold weather it has been found more convenient to discontinue the use of this tank, the wash water being circulated on the "closed circuit" plan. Where conditions are such that it is possible to change the wash water frequently, an outside tank is quite unnecessary.

The use of baffling in the washing tower would be unnecessary if a knothole mixer were provided similar to that in the solution system. This would be cheaper, and, on the whole, more satisfactory, provided the water pump could be adjusted to handle any desired volume. If an excessive amount of water were introduced with the blend into a knothole mixer, a considerable volume would probably be carried over into the settling tower.

Solution is frequently carried over into the washing tower. The available chlorine of this solution is of course lost. If a settling tower were provided between the treating tower and washing tower this solution could be recovered.

Plant Operation

When once the valves are adjusted and the speed of the pumps regulated, very little attention is required. The regular duties occupy less than one-fourth the time of one man on each shift. These duties consist of determining the strength of solution, adding fresh charges of bleaching powder, making doctor tests on the treated product and making such adjustments of valves and pumps as may be needed to care for changes in the volume treated. Repairs requiring more than a few minutes are made by the regular repair gang in the plan In making up fresh batches of solution the powder i drawn into the box through a chute from a dru located on a platform outside the building. The chut delivers the powder into a screen-bottomed box sus pended in the upper portion of the larger box. B spraying the powder with water delivered through hose and breaking the lumps with a shovel or hoe, i is possible to work the charge through the scree with a moderate dusting loss. The enriched solutio is transferred from the mixing box to the aëratin tower. The supply pipe to the mixing box is so cor nected that the box may be filled with fresh wate circulating wash water, or solution.

A more convenient method of putting the bleachin powder into solution is being devised. While all detail have not been agreed upon, a small tube mill will prob ably be provided into which the powder may be drawn water added, and the powder reduced to a fine stat of subdivision. This will increase the recovery c hypochlorite somewhat, but the chief gain will be i reduced dusting loss and increased comfort to th attendant.

When the blend is excessively cold, trouble is exper enced with the formation of "mush" ice in the knothol mixer and the treating tower. This trouble may b obviated by warming the solution between the pum and the knothole mixer.

Experience has shown that it is well to hold th level of the blend in the weathering tower quite lov Storage capacity to care for the accumulating blend i thus always at hand, should it be necessary to shu down the plant for a short time for repairs.

Corrosive Action of Bleach

It is well known that a solution of calcium hypo chlorite is corrosive to iron and brass, especially th latter. A word in regard to the effect of this solutio on pumps, pipes and the interior of towers is c interest.

Until very recently the solution pump has been use to draw the enriched solution from the mixing bo A considerable amount of undissolved lumps and gritt residue was always drawn out and passed through th pump. The natural result was a rapid impairment c wearing parts, necessitating frequent replacements an repairs. The effect of corrosion was thus masked an could not be accurately estimated, but it was certai that it was small in comparison with mechanical wea

At present the enriched solution is drawn from th mixing box into a submerged tank and elevated by ga pressure into the aërating tower. This should greatl prolong the life of the wearing parts of the solutio pump. Also, tests are being made with several pater alloys with promising results to date. It is probabl that the use of one or more of these for all wearin parts, in connection with relieving the pump fro handling gritty residue, will solve the difficulty.

After more than 8 months of service three sho lengths of pipe were removed from the solution lin for inspection. One, which was in contact with a bra valve at the discharge end of the pump, was found t be badly corroded. In the others an impervious linin about one-sixteenth of an inch thick had formed, whic had protected the pipe perfectly from corrosion. Thi lining was found to be largely calcium sulphate, wit some lime.

After the plant had been in operation more tha

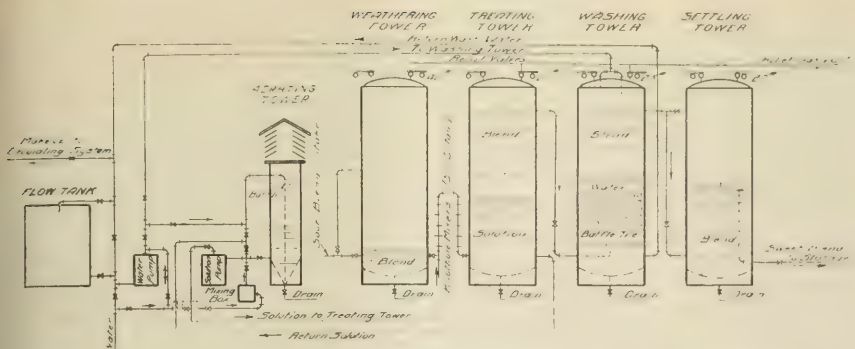

FIG. 2—DIAGRAMMATIC SKETCH OF GASOLINE SWEETENING PLANT USING BLEACHING POWDER

a year the manholes near the bottom of the treating tower and washing tower were opened and the interior of these towers inspected. The interior of the treating tower was found to be covered almost completely with a coating, which, however, was not as dense nor as adherent as the coating found in the solution line. Some corrosion had occurred, but when the accumulated oxide was scraped off, the metal beneath was found to be practically free from pitting. It is impossible to state whether the oxide was formed shortly after the plant was started and that corrosion had ceased, or whether it was the result of continuous action. Even if the second assumption were correct, it would require many years for corrosion to proceed so far that the tower would be in danger of failing.

Several feet of sediment, largely lime, was found in the treating tower. This was sluiced out with a hose. A tank with a cone-shaped bottom would permit the complete removal of this sediment at intervals while the plant is in operation.

Little corrosion had taken place in the washing tower. In spots the interior was somewhat roughened but for the most part it was smooth and bright. Some consideration has been given to the selection of a material suitable for lining the towers, should a more extended experience prove this necessary.

Resistant Materials

Tests are now in progress to determine whether acid-proof paint will withstand the corroding action of the solution. Test-pieces, thoroughly cleaned, were painted and immersed in the aërating tank. These tests have not proceeded far enough to warrant a decision as to the suitability of such paint for the purpose. A lead lining such as is used in acid-treating plants would undoubtedly give satisfactory service, but a zinc lining would be still more durable. This metal is practically inert when exposed to hypochlorite solution[3] and possesses the added advantage of being electropositive to iron.[4] Should it be decided to employ this metal, serious consideration should be given to the method of application.

The use of galvanized iron plates in the construction of those tanks which are exposed to the solution is not altogether satisfactory since the film of zinc would be broken in many places during the construction of the tanks, thus exposing the iron. Also the film of zinc deposited in the galvanizing process is not as thick as seems desirable for this purpose. A method which seems applicable was described by Henry Hess in *Chemical & Metallurgical Engineering* several years ago.[5] Finely powdered zinc, to which finely powdered lead and tin have been added, is mixed to a paste with a suitable flux and applied with a brush. By heating with a blast torch the metals are melted and form a tough, adherent coating. By adding the proper amounts of tin and lead it is claimed that greater toughness is obtained without losing the electropositive property of the coating.

Experience to date indicates that the oxide formed by contact with the hypochlorite solution furnishes quite efficient protection to the metal beneath. If the treating and washing towers were constructed from extra heavy steel there is little doubt that a long life could be obtained at moderate cost. For both solution and water lines the use of pipe galvanized inside is recommended.

Operating Practice

The consumption of bleaching powder is about 2.75 lb. per 1,000 gal., or 0.1155 lb. per barrel. This is somewhat higher than the consumption indicated by the preliminary tests. Probably the greatest contributing factor is the carrying over of solution into the washing tower. Other sources of loss are leakage of solution through the pump, exposure of solution in the aërating tower to diffused light and occasional overflows of the aërating tower.

As both the naphtha and the compression product are sour, it is necessary to sweeten the entire volume of blend. At present the plant is producing about 75,000 to 85,000 gal. of blend daily, which the treating plant is handling very satisfactorily. Construction is now in progress for doubling the output of the gasoline plant, and it is the opinion of the authors that the present treating plant, with possibly some minor changes, will handle the increased production.

Tests on Refinery Products

A series of experiments were made during the months of July and August, 1921, at the Midwest Refinery at Casper to test the adaptability of the process to refinery products. These tests proved that some heavy naphthas could be treated economically, while others could not be treated at all. Lighter naphthas could be treated, but with a somewhat higher consumption of bleaching powder than that experienced in handling the blend at Salt Creek. Gasoline which had passed the steam stills could be treated easily and economically. A large amount of such gasoline was in storage which the management was particularly anxious to prepare for market. It was decided to connect up four towers of a plant formerly used for treating pressure still distillate to form a plant for treating this product.

This improvised plant differed in some respects from the plant at Salt Creek. Since the gasoline was not "wild," the weathering tower was omitted. The towers were, in order, for treating, settling, washing and settling. All the towers were about about 20 ft. in height; the diameters were, in order, 5 ft., 5 ft., 6 ft. and 7 ft. Three pumps were used, one for gasoline,

[3] "A Comprehensive Treatise on Inorganic and Theoretical Chemistry," by J. W. Mellor, vol. 2, p. 253.

[4] "The Protection of Iron by Electroplating," by Oliver P. Watts and Paul L. DeVerter, *Trans. Am. Electrochem. Soc.*, vol. 30, p. 145.

[5] *Chem. & Met. Eng.*, vol. 16, p. 13, Jan. 1, 1917.

one for solution and one for wash water. The bleaching powder was mixed in a tank from which the solution would gravitate into the aërating tank. The pump drew the solution from this tank and forced it through the mixer into the treating tower, from which it was returned by pressure to the aërating tank or to the mixing tank, as desired. Due to the limited capacity for both aërating and treating, only about 4,200 gal. of solution could be handled advantageously. During the first continuous run, lasting over 20 hours, gasoline was treated at the rate of about 6,500 bbl. per 24 hours. This plant was operated until the entire volume of sour gasoline in storage was treated.

Very little solution was carried over into the first settling tower, but a considerable volume of emulsion was drawn from this tower. There was a decided tendency for the gasoline to be carried into the aërating tank with the returning solution. The treating tower was so small and the circulation of the solution so rapid that there was no opportunity for the mixture to "break," thus allowing the gasoline to rise and the solution to settle.

Chemical Tests

The details of preparing doctor solution and the procedure in making the test are described in detail in several publications.[6]

A standard solution of either sodium arsenite or sodium thiosulphate may be used in the determination of the available chlorine present in solutions and in samples of bleaching powder. A solution approximately tenth normal is convenient.[7]

In calculating the pounds of bleaching powder in solution the following formula may be used:

$$\frac{0.003546 \times (X) \times \frac{3785}{25} \times (Y) \times \frac{100}{Z}}{453.6} = \text{pounds of bleaching powder in solution.}$$

In this formula,

X = c.c. of $N/10$ sodium arsenite or sodium thiosulphate to titrate 25 c.c. of solution.

Y = gallons of solution in circulation.

Z = per cent of available chlorine in the bleaching powder.

For example, should $X = 15$, $Y = 3{,}000$ and $Z = 35$,

$$\frac{0.003546 \times 15 \times 151.5 \times 3000 \times 2.855}{453.6} = 152.6 \text{ pounds of bleaching powder in solution.}$$

Treatment of Emulsion

If any considerable volume of emulsion forms during treatment, provision for the recovery of the gasoline which it contains would probably be a paying investment. This emulsion should be collected in a lead-lined tank, permitted to settle, and the clear solution returned to the system. Some acid, either muriatic or dilute sulphuric, should be added and the contents of the tank thoroughly stirred. After being permitted to settle, the gasoline may be recovered and the sludge run to waste.

[6]Tech. Paper 214, U. S. Bureau of Mines, pp. 24-25; "Gasoline and Other Motor Fuels," Ellis and Meigs, pp. 59-60; "The Examination of Petroleum," Hamor and Padgett, pp. 59-60.

[7]Descriptions of methods of preparing standard solutions of sodium thiosulphate and sodium arsenite and for the determination of available chlorine in bleaching powder are contained in practically all books on quantitative analys's. Good descriptions may be found in "Analytical Chemistry," vol. 11, by Treadwell-Hall, "Quantitative Chemical Analysis," by Olsen, and "Quantitative Analysis," by Mahin.

Precautions for Economical Use of Bleach[8]

When dissolving bleaching powder all lumps must be broken up. This may be done in a box fitted with a screened bottom, suspended in water. To avoid dusting loss, the transfer of the powder from drum to mixing box should take place where there is no wind.

The powder should not be exposed to the air unnecessarily, especially where it can absorb moisture continuously.

The drums should be stored in a cool, dry, place.

The solution should be protected from diffused light as much as possible and never exposed to direct sunlight.

The solution should be maintained at the lowest strength compatible with safety of operation. This minimizes losses from both mechanical and chemical sources.

Provision should be made for aërating the solution, either by the splash method or by bubbling air through the body of the solution.

Careful attention should be given to the packing of valves and pumps. A seemingly small loss occurring frequently as in case of an improperly packed pump will soon amount to a considerable volume.

As little weathering as possible should be allowed to take place in the treating tower. Ebullition in this tower carries solution over into the washing tower. Loss from this source will greatly increase the consumption of bleaching powder.

Conclusions

The process described is not suitable for sweetening heavy naphthas, but is suitable for sweetening gasoline from the steam still or direct from the fire still, and is especially suitable for treating natural gas gasoline.

With a well-designed and well-constructed plant a large volume of gasoline can be sweetened with low cost for supplies, attendance and upkeep of plant.

Acknowledgments

The design and construction of the plant was under the supervision of W. R. Finney, superintendent of gas department; A. C. Andrews, superintendent of the Salt Creek gas plant, was in direct charge of construction. Both offered many suggestions which were incorporated in the plant, and have since helped in many ways in improving the operation of the plant.

E. Buddrus, laboratory foreman at the time the preliminary tests were being made, exercised painstaking care in making these tests.

A. J. L. Hutchinson, who joined the staff after the plant was in operation, has aided in clearing up some of the chemical problems which were not fully investigated when the details of the process were being worked out, and has also offered valuable suggestions in the preparation of this article.

Sensitiveness of Gasoline Vapors to Ignition

Tests have been conducted at Pittsburgh, Pa., by the United States Bureau of Mines to obtain data as to the comparative sensitiveness of gasoline vapors and methane with respect to their ignition from electric flashes

[8]The properties of bleaching powder are covered in great detail in "A Comprehensive Treatise on Inorganic and Theoretical Chemistry," by J. W. Mellor, vol. 2, p. 258 *et seq.* Information of value is also contained in "Outlines of Industrial Chemistry," by Thorp, 3rd ed., pp. 132-135.

A New Induction Furnace*

By J. Murray Weed

Power and Mining Engineering Department, General Electric Co., Schenectady, N. Y.

IT IS the object of this paper to describe a new induction furnace for melting non-ferrous metals, possessing some features which differ radically from those found in any previous furnace and affording great flexibility of design and a broad scope of application.

In this furnace, as in other induction furnaces, the heat is produced by an electric current induced by transformer action in a looped portion of the molten charge, which we will call the secondary. This secondary is distinct from the melting chamber pot, in which the cold charge is received, melted and held for refining and pouring. The success of the furnace depends upon a continuous, automatic circulation of the molten metal between the secondary and the melting pot, to prevent overheating in the former and to deliver the heat to the cold metal in the latter. It is in the form of the secondary, and in the character of the circulation and the method of producing it, that the new fundamental features of this furnace are found.

The secondary loop in this furnace closes upon itself without passing through the melting chamber, as illustrated by sectional views in Fig. 1. It is in the form of a hollow cylinder, of considerable length, which communicates with the melting chamber through two distinct ports or passages, from opposite ends of the cylinder. The current flows around the cylinder in a circumferential direction without entering the chamber or communicating passages, while the circulating charge flows through it in an axial direction, transverse to the current. The movement of the molten metal is unidirectional, from the secondary cylinder to the melting chamber by one passage and from that chamber back to the secondary by the other.

Mechanism of Circulation in Secondary

The circulation in this furnace is effected by the force of electromagnetic repulsion, set up through the medium of the magnetic leakage field, which exists between primary and secondary in any transformer. This force is proportional to the square of the current flowing, and is familiar to all transformer engineers as having caused much trouble in the wrecking of transformers when the windings were not held with sufficient rigidity to withstand the enormous forces of this nature which are set up when short circuits occur.

The induction furnace is, in fact, a special case of a short-circuited transformer, in which the internal impedance is comparable with the total full load impedance of the secondary circuit of the ordinary transformer. The repulsive force in this furnace, therefore, is not excessive, as in ordinary transformers when short-circuited, but only such as exists in ordinary transformers when normally loaded.

Some explanation may assist in understanding how this repulsive force becomes effective in producing circulation of the molten material through the secondary, while the secondary itself is fixed in position.

In the case of an ordinary transformer, with solid secondary, relative motion between primary and secondary occurs only when the strength of the structure supporting the windings is not sufficient to withstand the force corresponding to the current flowing, and when such motion does occur, the current and its conducting medium, the solid metal of the coil, necessarily move together. In this furnace the case is quite different. The repulsive force will always be small, relative to the physical strength of the structure as a whole, and while the secondary current and the position of the secondary do not shift, yet the secondary conducting medium can and does flow. This difference is understood after considering the nature of the magnetic leakage field, which is the same in both cases, and the natural effect of the modified conditions upon its action.

The physical characteristics by which any magnetic field makes itself apparent are those of mechanical attraction and repulsion, and of inducing voltages in conducting media when relative motion not parallel to the field occurs between it and the conducting medium. A force of attraction exists between unlike magnetic poles, while a force of repulsion exists between like poles. The former force is due to a tractive effort or tensile stress exerted by the field in directions parallel to itself, while the latter is due to a pushing effort or compressive stress in a direction at right angles to the field. These stresses are true mechanical stresses, measurable in grams per sq.cm. or pounds per sq.in., which exist simultaneously in any magnetic field and which produce the results which such stresses would be expected to produce.

The stress involved here is that of pressure at right angles to the field, this field being the leakage field between primary and secondary. In the case of the solid secondary of the ordinary transformer, if it is free to move, bodily motion will be produced. If it is properly supported, although mechanical pressure is produced, no movement occurs. In the case of the fluid secondary of the furnace, the mechanical pressure appears as a fluid pressure and even though the secondary as a whole is not free to move, this fluid pressure, if not uniform and if permitted to do so, will cause the metal to flow from points of higher pressure to points

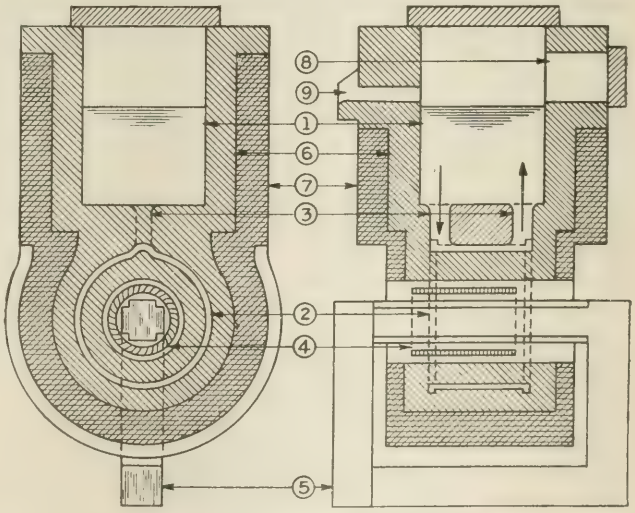

FIG. 1—TWO VERTICAL SECTIONS OF THE FURNACE AT RIGHT ANGLES TO EACH OTHER

Primary winding; 5. Laminated iron core; 6. Refractory lining; 7. Thermal insulation; 8. Charging door; 9. Pouring spout.

Note the thickened sections at the ends of the secondary cylinder, one serving as a channel for distributing the metal around the perimeter of the cylinder and the other for collecting it. The flow within the main body of the cylinder is in an axial direction.

Note the axial displacement of the primary winding with respect to the secondary. The velocity of the circulation of the metal may be varied by shifting the position of this winding.

*Paper presented at the forty-second general meeting of the American Electrochemical Society in Montreal, Sept. 21, 22 and 23, 1922.

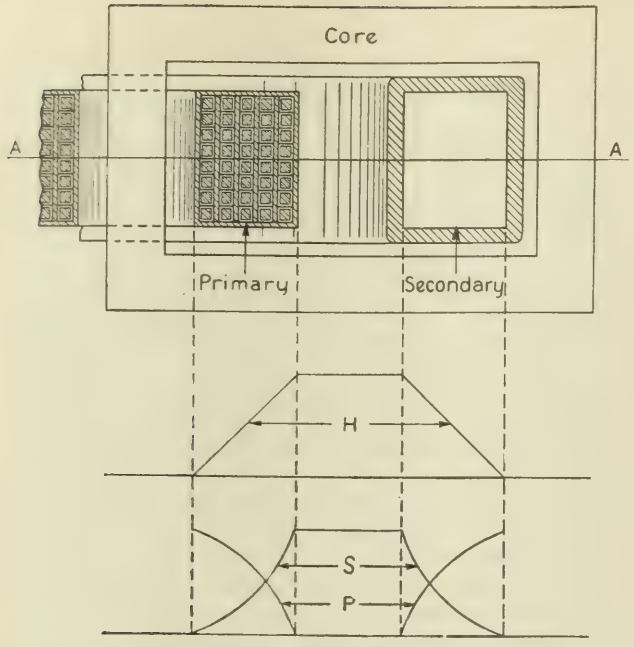

FIG. 2—TRANSVERSE SECTION THROUGH PRIMARY AND SECONDARY OF A HYPOTHETICAL FURNACE, WITH CURVES

H shows the variation of the density of the magnetic leakage field between primary and secondary along lines parallel to *A-A*.
S shows the variation of the stress in the field which is proportional at every point to the square of the density.
P shows the variation of the fluid pressure in the molten metal. The difference between the fluid pressures at two points is equal to the difference between the corresponding stresses of the field. The maximum fluid pressure occurs in the part of the secondary most distant from the primary where the minimum stress is found.

of lower pressure. It remains now to show that the pressure is greater at certain points in the secondary than at certain others, and to show how this pressure difference is utilized to produce the desired circulation.

The leakage flux between primary and secondary is not all confined between their adjacent boundaries. This matter has been carefully investigated for transformers, and for an arrangement with transverse cross-section, such as is illustrated in Fig. 2, for instance, the distribution of the leakage field is shown by the curve *H*, the ordinates representing the magnetic densities at points along lines parallel to *A-A*. In both primary and secondary, the density falls away gradually, from its maximum value at adjacent boundaries, and disappears at the further boundaries. As the stress in the field at any point is proportional to the square of the density, the variation of the stress along the line *A-A* is in accordance with the curve *S*. This, however, does not signify that the mechanical or fluid pressure imparted to the secondary (or primary) is represented at each point by the ordinate of curve *S*.

Were the density of the field uniform throughout, the magnetic stress at any point would be counterbalanced by equal stresses at all other points, and no mechanical pressure would be imparted to the material medium. It is only the difference between the magnetic stresses at given points in the secondary that appears between those points as mechanical pressure.

If the differentials of pressure be added along the line *A-A*, from the side of the secondary nearest to the primary to the side farthest from it, the integrated or effective pressure will be represented by curve *P*, such that the ordinate of *P* at any point added to the ordinate of *S* equals the maximum value of *S*. The ordinate of curve *P* at any point represents a pressure difference between that point and a point at the side of the secondary nearest to the primary.

In the case of the fluid secondary found in the furnace, this pressure difference constitutes a difference of fluid pressure. It cannot equalize itself within the secondary, since it is opposed by the stresses of the field which sets it up. If, however, a passage or passages be provided external to the secondary, from the point of maximum pressure (farthest from the primary) to the point of minimum pressure (closest to the primary), as illustrated in Fig. 3, the pressure difference will cause the fluid to flow, as indicated by the arrows.

The pressure causing this flow will be maintained by the field, with a corresponding internal flow from the point of minimum pressure to the point of maximum pressure. The strength of flow will be such that the sum of the internal and external pressure drops due to friction will be equal to the total pressure imparted or generated by the field.

Figs. 2 and 3 have been used here for the purpose of illustrating, in the simplest manner, the principle involved. The arrangement of primary and secondary in the furnace, as actually developed and represented in Fig. 1, differs from that in Figs. 2 and 3 for practical reasons, but the principle is the same. Maximum and minimum fluid pressures are found at the ends of the secondary cylinder which are respectively farthest from and nearest to the primary winding as a whole, or to use a form of expression common with transformer designing engineers but somewhat lacking in definition, at the ends which are farthest from and nearest to the magnetic center of the primary winding. This pressure distribution results from the diagonal arrangement of the leakage field, due to the axial displacement between the primary and secondary. It is the radial component of this field which generates the pressure difference between the two ends of the cylinder.

That the axial forces set up in such an arrangement are substantial realities has been demonstrated by experience in transformers with windings of the concentric cylindrical type. Comparatively small axial displacements of these windings have, upon numerous occasions, resulted in crushing the mechanical supports of the coils and deforming the coils themselves, the primary being driven in one direction against the yoke

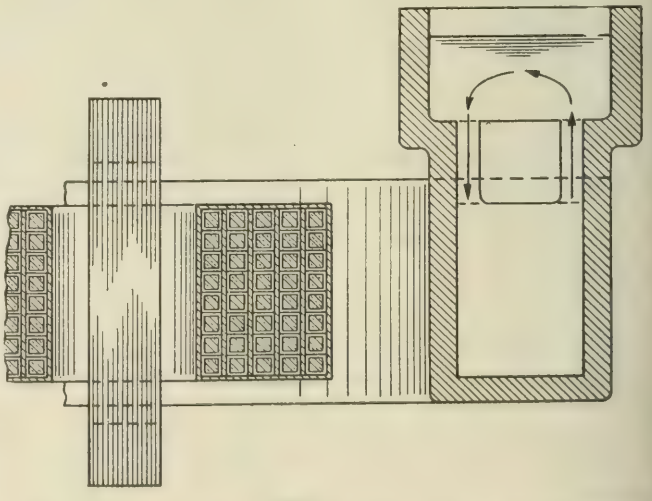

FIG. 3

Section of hypothetical furnace shown in Fig. 2, perpendicular to the section in that figure. The arrows show the way molten metal would flow through the external channel and reservoir, from the point of higher fluid pressure in the secondary to the point of lower fluid pressure.

of the core, and the secondary in the other. The differences in fluid pressure between the two ends of the secondary cylinder in the furnace are demonstrated by the flow of the molten metal in the furnace. Any reasonable velocity of the circulation can be easily obtained, by merely adjusting the axial position of the primary winding with respect to the secondary, for which provision is made in the mechanical design of the furnace.

As intimated at the beginning of this paper, the chief significance of the new physical features which have been described above lies in their effects upon flexibility of design and scope of application. The free unidirectional circulation, set up by a force which can be controlled within desirable limits, not only restricts the temperature variation of the metal to a small value but also avoids the danger of magnetic choking.

This makes it practicable to force the furnace to any extent which is feasible for the primary winding and core, and particularly adapts it for the melting of high conductivity metals, such as copper, as well as of metals of lower conductivity. The form of the secondary is favorable to flexibility of design as regards size and capacity. The only limiting feature in this direction consists in the refractory lining, due to considerations of mechanical strength and general reliability. Such limits are probably capable of indefinite expansion. Increased size and capacity will have no necessary effect upon the power factor, which is inherently high with the long thin section of the secondary.

Notes on the Swedish Paper Industry

IN *Commerce Reports* for Aug. 21, 1922, there is an interesting summary of the history and present status of the paper industry in Sweden. The establishment of the Swedish paper industry dates back to the sixteenth century, but it was not until recent years that it came to occupy a place of prominence in Swedish economic life, and the firm establishment of Swedish paper as an article of export is of still more recent date.

The Swedish mills are thoroughly modern, employing electrical power to a great extent, and produce a great variety of paper, such as newsprint, wrapping, parchments, smooth foolscap, writing, thin printing, colored tissue, crêpe and waxed tissue, affiche, catalog, envelope, sealings and toilet. Production of cardboards includes leather board, duplex and triplex boards.

There are at present 74 mills in Sweden, with a total yearly capacity of 400,000 tons of paper and 75,000 tons of cardboard. Of this amount, approximately 45 per cent is exported. While most of the mills are comparatively small, some are quite large, the three most important (Karan, papyrus, and Holmen) having yearly capacities of from 30,000 to 50,000 tons. The chief grades produced for export are newsprint and wrapping paper, both of which enjoy an excellent reputation in foreign markets.

Great Britain has always been the chief market for Swedish paper products and remained so during and after the war, with France, Brazil, Australia, Denmark, Hungary, Argentina and Rumania following in the order named. Exports to the United States, especially newsprint, have increased steadily. The total exports of newsprint from Sweden to the United States in 1912 amounted to only about 300 tons, while the estimated figure for 1921 reached 30,000 tons. The growing importance of the American market to Swedish paper manufacturers can best be appreciated when it is noted that, of the 12,345 tons of newsprint exported during May, 1922, 7,000 tons were shipped to the United States.

Exports of Swedish Papers

The following table shows exports of Swedish newsprint and other paper and cardboard during 1913, 1920, 1921 and the first 5 months of 1922:

SWEDISH EXPORTS OF PAPER AND CARDBOARD

Years	Newsprint, Tons	Other Paper, Tons	Total, Tons
1913	61,650	151,020	212,670
1920	116,430	169,760	286,190
1921	111,530	71,570	183,100
1922:			
January	10,360	7,980	18,340
February	3,560	4,950	8,510
March	6,600	12,250	18,850
April	5,070	7,730	12,800
May*	.....	.....	26,000

* Estimated.

The preceding table illustrates the extreme depression which the Swedish paper industry suffered during 1921 and from which it is now very slowly recovering. The crisis is by far the most serious experienced since the industry's establishment. The competition from the countries with low-value exchanges, such as Finland and Germany, has been keenly felt, because both of these countries possess large and highly developed paper industries.

Furthermore, the cost of production for the Swedish mills was for a long time kept above a point permitting successful competition, because of the extraordinarily high wages which were being upheld by strongly organized labor.

Recovery of Industry Expected in 1922

Developments which have so far taken place during 1922 promise a return to normal conditions. Production costs have been cut considerably through wage reductions averaging from 25 to 40 per cent. Furthermore, the competition from Finland, while still felt, is not so severe and that from Germany is rapidly disappearing, owing to the steady rise of German prices toward world market levels and the difficulties experienced by German manufacturers in effecting prompt deliveries. On June 15 all mills except those producing boards were running at full capacity and were reported as having advance orders assuring steady occupation for some time to come.

Organization of Paper Manufacturers

Practically all Swedish paper and cardboard manufacturers are organized in what is known as the Sveriges Papperbruksforening (Swedish Paper Manufacturers' Association), which is a general trade organization serving the industry much in the same way as other trade organizations do their industries, without having any price regulations or control features.

During the last week of June an export association has been formed by Norwegian, Swedish and Finnish paper manufacturers of newsprint. The scope of this association is not yet known, but it is understood that it is organized for the sole purpose of promoting sales of Scandinavian and Finnish newsprint in the United States. It is reported that German exporters are to be affiliated with the new export organization.

Non-Metallic Inclusions and Ferrite Segregation in Steel*

Traces of Manganese and Sulphides Are Present in the Steel Surrounding a Sulphide Inclusion, and Cause Precipitation of Ferrite Shells—Such Tiny Inclusions Have Much to Do With the Locus of Excess Ferrite

By E. G. Mahin and H. W. Botts
Department of Chemistry, Purdue University

In THREE earlier papers[1] experimental evidence has been submitted indicating that the effect of non-metallic inclusions upon carbon segregation in steel is due to the fact that in a narrow surrounding zone the steel is saturated with the material of the inclusion itself and with equilibrium products of reactions between the inclusion material and other constituents of the steel. In this zone the ideal equilibrium between austenite and ferrite at the upper transformation point is upset by the dissolved impurities so derived, this resulting in premature ferrite separation. As soon as such separation begins, the supersaturation of austenite with ferrite, as it ordinarily exists at Ar_3, is relieved by continued separation about these localities.

Reference was made to Stead's theory[2] that iron phosphide is alone responsible for ferrite segregation, the presence of inclusions in the same localities being regarded by him as a coincidence, rather than a cause. But we called attention to the fact that iron phosphide is probably only one of a considerable number of such impurities, any of which may exert a similar influence. There is reason for believing that many of these may come from non-metallic inclusions, remaining permanently segregated about the latter.

Segregation of ferrite and cementite about non-metallic inclusions is a phenomenon that has long been familiar to metallographists; the only difference of opinion is with regard to the cause. Most of the theories that have been proposed also are familiar. Ziegler's theory[3] that inclusions act as crystallization nuclei for ferrite has never been generally accepted. Howe supposed[4] that inclusions are rejected from crystallizing austenite to the grain boundaries, where ferrite also is expelled during passage through the temperature range Ar_3 to Ar_1. It was shown by one of us[1] that neither Stead's nor Howe's theory accounted satisfactorily for all of the observed cases. The form and relative positions of inclusions remain practically unaltered by protracted and repeated heat-treatment that totally changes pre-existing grain sizes and forms. Such treatment results also in complete elimination of ghosts of phosphorus and ferrite in rolled steel, but it does not eliminate, in any degree, ferrite segregation about inclusions.

Oxidized Inclusions

Giolitti has vigorously supported[5] his conclusion that it is only "oxidized" inclusions that show any effect upon ferrite segregation and that if the steel is cooled during or immediately after carburization, inclusions do not surround themselves with ferrite. He has argued that the well-known fact that all steels contain certain quantities of dissolved gases is responsible for the reversible reaction within the body of the steel:

$$3Fe + 2CO \rightleftarrows Fe_3C + CO_2$$

the equilibrium of which is shifted in either direction, according to whether the piece is bathed in oxidizing or in reducing gases. The "oxidized" inclusion would be supposed to suppress this reaction to some extent, thus producing a thin sheath of ferrite about the inclusion, which would naturally act as a nucleus for further ferrite crystallization. On the other hand, if the piece of steel were heated in a reducing atmosphere, the resulting carburization and excess of carbon monoxide would be expected to prevent the "free iron" formation. In the last paper just cited Giolitti stated that if a piece of steel[6] containing ferrite segregated about inclusions be heated to a temperature of 1,000 deg. C. for 24 hours in carbon monoxide, ferrite segregation is eliminated, only to reappear if the piece is reheated in carbon dioxide.

In none of the available papers by Giolitti nor in his book "Heat-Treatment of Soft and Medium Steel" is there given any clear definition as to what are to be considered as "oxidized" inclusions. It is difficult to see how such inclusions as sulphide of manganese (the most common and abundant of all inclusions in even the "cleanest" steel) or sulphide of iron could be oxidizing in any sense of the word, and we are quite certain that the ubiquitous manganese sulphide is one of the most active of all inclusions in connection with ferrite segregation. If the "oxidized" inclusions are to be understood as being, for the most part, of the general nature of silicates (the ordinary slag inclusions of iron and steel), it is worth our while to examine the thermochem-

[6] [Dr. Giolitti's experiments were made on medium carbon-chromium and nickel steels made in an acid open-hearth furnace.—Editor.]

istry and the general physical conceptions involved in Giolitti's assumptions.

If this is the true mechanism of ferrite segregation about inclusions, any influence of the material of the inclusion upon the shifting of equilibrium conditions of the reaction expressed above would mean, as a *net* result, that carbon would be oxidized at the expense of silicon dioxide of silicates. The relatively large positive heat of oxidation of silicon ($Si + O_2 = SiO_2 + 180{,}000$ cal.) and the heat of formation of iron carbide ($3Fe + C = Fe_3C + 8{,}460$ cal.) makes it appear improbable that more than a very minute amount of carbon could be oxidized at the expense of silicon dioxide, even at high temperatures. Without regard to intermediate steps, the following changes are to be considered as representing final conditions:

$$SiO_2 + 2Fe_3C \rightarrow 6Fe + 2CO + Si$$

$$[2(29{,}160 - 180{,}000 - 2(8{,}460) = -138{,}600] \text{ cal.}$$

Naturally such a reduction of a silicate would involve the simultaneous formation of some sort of silicide. We have no thermochemical data regarding this reaction, but it does not seem likely that its consideration would materially change the conclusion that equilibrium would be established by a very slight reduction of the silicate, even at 1,000 deg. C. Of course there is to be considered also the possibility that the action of the inclusion may be of a catalytic nature.

If the inclusions that are considered to be responsible for ferrite segregation are understood to be oxides (of nickel or chromium?) only, we still have to account for the fact that plain carbon steels show the same effects.

The second objection to this conception lies in the difficulty in understanding how the preponderance of carbon dioxide or of carbon monoxide in the atmosphere surrounding the piece as a whole could have any such effect as Giolitti outlines at the surface of contact between metal and inclusion. A change in outside environment would, of course, alter the relative concentrations of the respective gases dissolved in the metal, but these gases would have to diffuse through the body of the steel in order to reach the inclusion and there seems no good reason why their action upon carbides should be delayed until contact with inclusions is established, unless the latter act as adsorption or catalytic centers—a hypothesis in support of which there appears to be no experimental evidence. In other words, if an inclusion acts at all in the sense of surrounding itself with an envelope of carbonless iron, this action should be noticed, no matter what might be the nature of the surrounding gases and, furthermore, the effect should be more striking in the case where the average carbon content is being *increased*, rather than decreased—that is, in the case where the piece is heated in a reducing atmosphere. This is because in such a case there would be the greatest possible difference between carbon content near the surface of the inclusion and that at a distance from it. This is the opposite of the conclusion as stated by Giolitti.

Ferrite Separation a Physical Process

In the attempt to understand the mechanism of the separation of ferrite in a cooling steel it is well to recall that this is a physical separation from a true solution and not simply a chemical oxidation of a compound. In order to act as a nucleus for continued crystallization of ferrite, any oxidation of carbon would have to *precede* the normal separation at the point that would otherwise be Ar_3. Whether austenite be regarded as a solution of elementary carbon or of iron carbide in iron (and this point appears to be more or less of a quibble, in the light of X-ray evidence as to the probable crystal lattice of the solution), the only sense in which "free" iron has any meaning is with reference to iron actually thrown out of solution as ferrite. Considering the system above Ar_3, if there is a certain amount of oxidation of carbon at the surface of the inclusion, the excess iron so produced is not essentially different from iron already present as a solvent for carbon and the only obviously possible effect would be a slight local increase in the per cent of iron in the solution. This, it is true, would promote a slightly greater ferrite supersaturation of the cooling solid solution, with consequent breaking down of austenite at these points slightly earlier than at others. The inclusions, then, if active as oxidizing agents (catalytic or direct as Giolitti supposes), should be regarded as surrounding themselves, when above the transformation range, with a zone of austenite slightly poorer in carbon than the average of the steel, rather than with a film of "free" iron. This action should be more or less independent of the nature of surrounding atmosphere. Considering the extreme narrowness of the zone of influence of the inclusion and the very appreciable speed of diffusion of carbon in austenite, one can scarcely suppose that this sort of action can be very important unless oxidation, with consequent gas production, is a continuous process. This is extremely unlikely. It may be remarked also that oxidizing inclusions should exert the opposite effect in hypereutectoid steel, being then found in pearlite grains—a supposition that is contrary to observed facts.

Ferrite May Segregate After Carburization

The foregoing paragraphs contain a brief discussion of some of the theoretical objections to the hypothesis that ferrite segregation about non-metallic inclusions is due only to the oxidizing properties of the latter. We may now mention an even more important objection in the fact that our own experimental results lead in the opposite direction. In Giolitti's paper on flaky and woody structures[7] the statement is made that if a piece of hypoeutectoid steel showing co-segregation of ferrite and inclusions is heated for 24 hours at 1,000 deg. C. in carbon monoxide, it no longer shows ferrite segregation, while if it be reheated in carbon dioxide the ferrite grains again surround the inclusions. We have heated a piece of 55-point carbon steel at 1,100 deg. C. for 72 hours in a cast-iron crucible and covered with fusible glass[8]. The environment here was certainly not oxidizing in nature. On the contrary, the portions of the piece that were in contact with the gray iron crucible were highly carburized, the effect being similar to that of ordinary case-carburizing. Fig. 1 shows a section, longitudinal to the direction of rolling, taken where the carbon had approached eutectic proportions and where, presumably, it was still increasing when the piece was furnace-cooled. Ferrite segregation is as pronounced as before. Transverse sections at higher magnification, taken at points in the interior of the piece, where the carbon had not increased to any notable degree but where the conditions were necessarily slightly reducing, show inclusions surrounded by much thicker shells of

[7] *Chem. & Met.*, vol. 20, p. 271 (1919).
[8] *J. Ind. Eng. Chem.*, vol. 11, p. 739 (1919).

ferrite. Fig. 2 illustrates a similar state of affairs in another piece. A ½-in. rod (0.07 per cent carbon) was packed in a carburizing mixture and heated at 1,000 deg. C. for 6 hours. A deep case was thus produced and Fig. 2 represents a portion near the inner border of the eutectoid zone.

The results of these experiments would not seem to indicate any necessary connection between the existence of an oxidizing atmosphere and co-segregation of ferrite and inclusions.

Inclusions as Centers of Contamination

Manganese sulphide is usually regarded as being formed by the reaction of manganese which has been added to liquid steel containing ferrous sulphide, the latter probably being largely in solution at this temperature. The formation of MnS inclusions would then be the result of precipitation from solution, analogous to precipitation by ordinary reactions in ordinary solutions. The reaction

$$Mn + FeS \rightleftarrows MnS + Fe$$

supersaturates the solution with MnS before precipitation begins. Under conditions otherwise static, equilibrium would finally result with the mother liquor saturated with MnS and containing a certain definite concentration of FeS. McCance[9] does not regard this reaction as being a "balanced" one, but his view can be correct only in a relative sense, for, even though the concentrations of Mn, MnS and FeS in the liquid immediately surrounding the precipitated globule may necessarily be very small, we are not justified in regarding either the formation or the precipitation of MnS as being absolutely complete. As the steel further cools through the region between the liquidus and solidus, these particles are usually caught between large austenite grains, and here they remain in the finally cooled solid steel.

We may assume also that metal in contact with each particle of true slag or of any other suspended material is saturated with the material of the inclusion and with products of any possible reaction between this material and iron. This statement does not imply that inclusion material is soluble to any large degree, but our ideas of physical equilibria make us reluctant to conclude that these particles could have zero solubility.

This conception leads to the conclusion that nonmetallic inclusions in iron and steel (and alloys as well) must always be surrounded by zones of segregation in which the metal is contaminated by soluble impurities or by eutectoids of these with the material of the body metal, and that no amount of heating can serve to eliminate this, because the supply is practically inexhaustible. No doubt these zones are extremely narrow in some cases, and the concentration of the contaminating elements or compounds is probably nearly always very low. But only a trace of such material is needed to upset the stressed condition which obtains as the solution cools past the ideal transformation point, and only a trace of ferrite, separated as a result of the influence of this material, is required to "seed" the solid solution and thus to start the breakdown of austenite.

[9] *J. Iron & Steel Inst.*, vol. 97, p. 239 (1918).

FIG. 2.—CORE OF 0.07 C STEEL, CARBURIZED AT 1,000 DEG. C. × 250

Fig. 3—Carbon steel heated after being plugged with aluminum bronze. × 100.

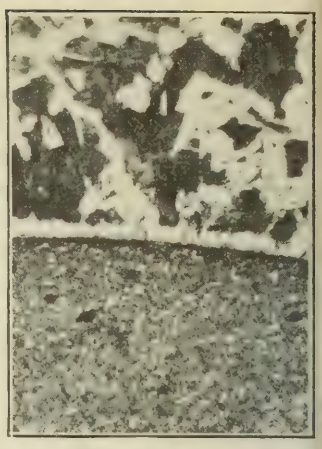

Fig. 4—Carbon steel heated after being plugged with high-speed steel. × 100.

Inclusions are occasionally found touching grains of pearlite or even entirely imbedded in them. We should expect certain exceptions of this kind, in view of the fact that constantly shifting temperature gradients involve corresponding shifts of dissolved impurities, including the contaminations associated with the inclusions as well as the carbon itself. This movement of dissolved matter may occasionally leave a given side of an inclusion unprotected, with the result that on this side there will be no premature ferrite separation.

We should note also that the most obvious cases of inclusions lying in pearlite grains are usually to be found in steels that are of nearly eutectoid composition. In such steels there is a very short temperature range between Ar_3 and Ar_1, the entire breakdown of austenite occurring in such a short space of time and from a system containing so little excess of ferrite that the latter could not possess any very great migratory power. Inclusions can then show little or no effect upon ferrite separation.

Experimental evidence has already been presented[10] to show that, in many cases, segregated impurities in hypoeutectoid steel cause decided segregation of ferrite and that phosphorus segregation is only one of many similar causes of this phenomenon. Specimens of the steel, into which had been driven small rods of dissimilar materials, were heated. These rods were of non-ferrous alloys and also of steels similar in composition to the body steel, except that each insert contained an abnormal per cent of some one element. After holding such composite specimens at temperatures above the transformation range for varying periods of time and then cooling in the furnace, the insert was often found to be surrounded by a well-defined ferrite ring. (Figs. 3 and 4.)

Oxidation Rings

Probably every metallographist has noticed that at times a polished specimen persistently develops minute

[10] *J. Ind. Eng. Chem.*, vol. 12, p. 1090 (1920).

dark spots which prove to be colored rings or halos with non-metallic inclusions at their centers. These rings usually form while drying the polished and washed specimen, either before or after etching, although they may appear also if the specimen is permitted to heat slightly during the final polishing or if it is heat-tinted. Colored rings are merely one example of selective oxidation. They indicate potential differences existing between the zones immediately surrounding the central inclusions and the main portions of the metal, and these potential differences are undoubtedly due to slight differences in the chemical composition of the metal at various distances from the inclusion. It seems obvious either that the inclusion is a source of contamination for the metal or that the metal retains a trace of the substance which was not expelled during the process of precipitation at high temperatures or upon cooling.

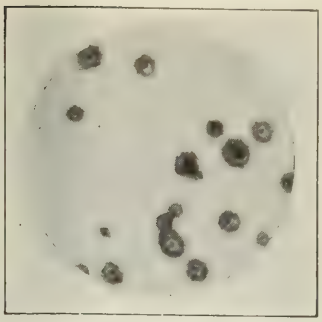

Fig. 5—Oxidation halos on Thermit iron; developed during drying of polished section. × 100.

We have examined a large number of oxidation rings in wrought iron and steel; some are shown in Fig. 5.

Whiteley's antimony solution[11] (5 grams of gelatin, 5 c.c. of glycerine, 0.05 gram of tartar emetic and 1 c.c. of dilute sulphuric acid in 20 c.c. of water) and McCance's silver nitrate modification[9] (substituting 0.1 gram of silver nitrate for tartar emetic) were applied to some of these materials to determine whether sulphide inclusions were centers of segregation. The evolution of minute gas bubbles, which were caught in the overlying gelatin, made it necessary to strip off the gelatin films before microscopic examination, and we finally omitted the gelatin entirely, simply dipping the specimen in the solution for a short time, then gently washing and drying.

Silver nitrate is not satisfactory for this purpose. Well-defined dark rings were produced, but the silver sulphide in thin layers is so nearly the color of the oxide rings that it was often impossible to decide whether the rings finally remaining were silver sulphide or iron oxide, the latter developed during drying. Antimony nitrate solution with the gelatin omitted is excellent for the purpose. Antimony sulphide is so distinctly yellow that it is easily distinguished (Fig. 6).

The alternating concentric rings, often constituting the halos of sulphide inclusions, are zones of higher concentrations of soluble sulphides. Their periodic recurrence is possibly due to different rates at which the various soluble impurities diffuse. With manganese sulphide inclusions we have to consider MnS, FeS and Mn, since all are presumed to be present at equilibrium.

From the results of these experiments it is possible also to confirm the assumption often made, that many of the small slate-gray inclusions found so abundantly in even high-grade steel and iron are sulphides, the natural assumption being that they are principally manganese sulphide. Even when the inclusion is so small as to make identification from its own appearance very difficult, the yellow antimony sulphide halo leaves no doubt as to its general nature. The application of the modified McCance's solution to the mottled "slag" inclusions of wrought iron and low-grade steel confirms the usual supposition that the lighter parts of these bodied are sulphides (Figs. 7 and 8).

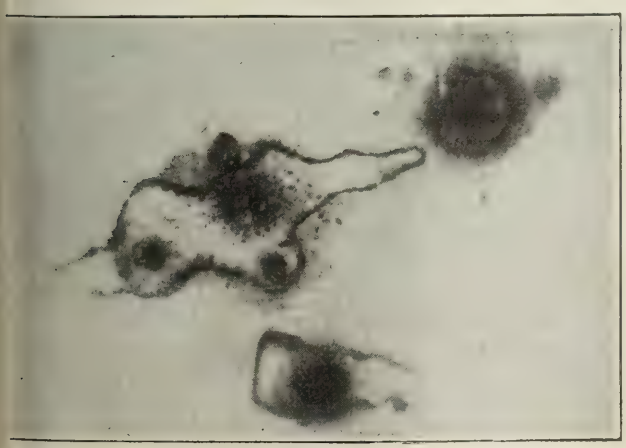

FIG. 6—ANTIMONY SULPHIDE HALOS ON POLISHED SPECIMEN. × 250

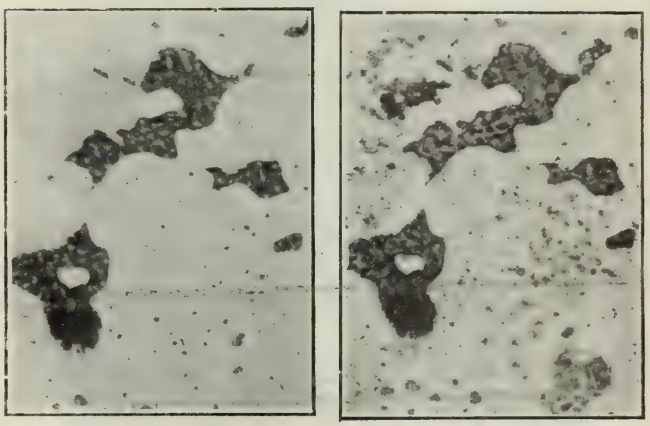
Genesis of Ferrite

In his paper dealing with this subject[12] Giolitti reasoned that ferrite is not expelled to the peripheries of



FIGS. 7 AND 8—TWO VIEWS OF SAME AREA ON WROUGHT IRON. × 100

Fig. 7—Unetched. Fig. 8—Etched with McCance's silver solution.

cooling austenite grains, as maintained by Howe[4] and others, but that it first separates at austenite grain centers as small β-grains, which coalesce as they grow, finally forming a semblance of a network. This assumption seems logical if we are to consider only hypoeutectoid steels, *cooling from the liquid state*. The mechanism of the crystallization of austenite between the liquidus and the solidus leads necessarily to the formation of grains in which the carbon content is lowest at the nuclei and highest in the outer portions. The natural tendency of grains of the solid solution to reject their excess ferrite to their boundaries at Ar_3 is then counteracted by the fact that the grain centers reach their transformation temperature first. We should then expect a preliminary formation of either (*a*) isolated ferrite dots alone, near pearlite grain centers, or (*b*) ferrite dots and ferrite network, according to the rate of cooling between the solidus and Ar_3, slower cooling favoring an approach to equalization of carbon content in the grains.

[12] *Chem. & Met.*, vol. 22, p. 737 (1920).

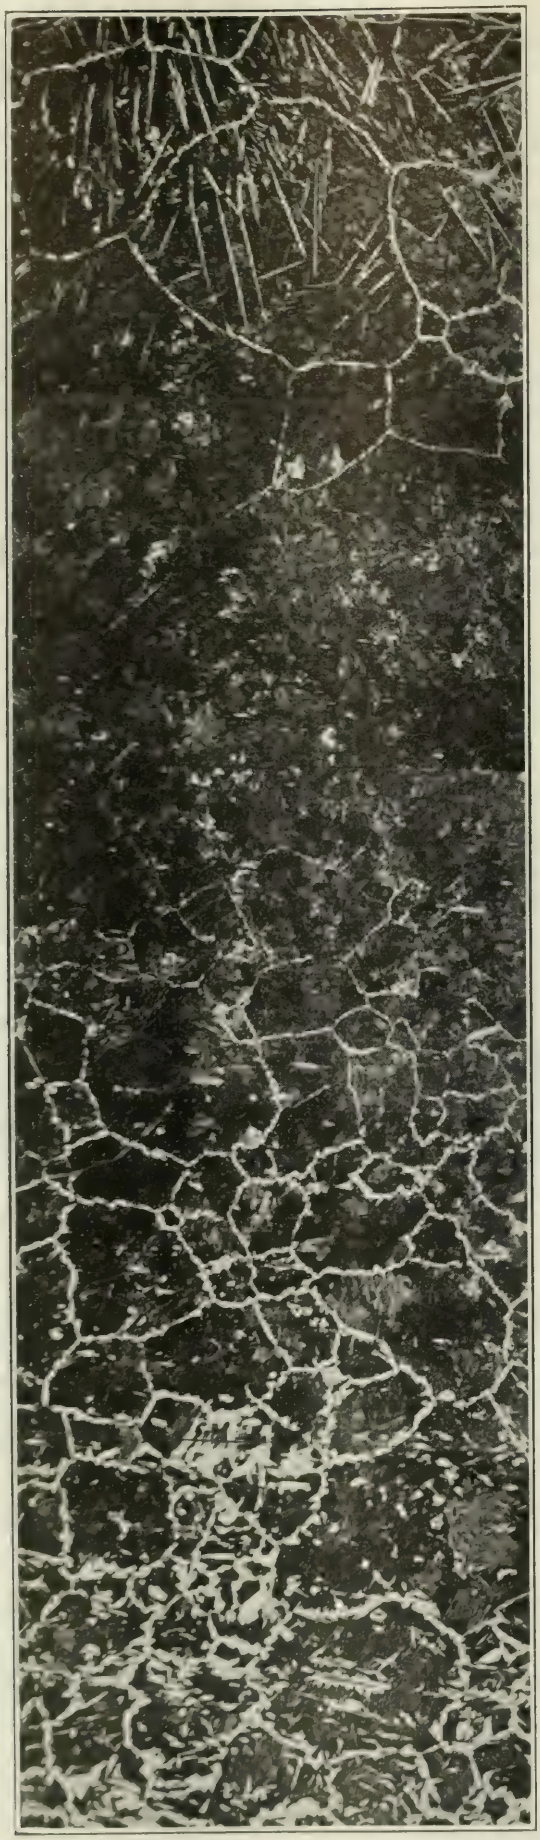


FIG. 9—SECTION ACROSS THE CARBURIZED CASE OF STEEL SHOWN IN FIG. 1. × 50

But if this conception is correct for steel castings cooled not too slowly from the liquid state, the case must be quite different for the reheated steel, which is far more common and important in practice. No matter by what mechanism the ferrite network was first formed when the piece is reheated this network will define a new system of austenite grains whose carbon content will be *highest* at centers. Absorption of the network begins at Ac_1 and is completed at Ac_3. It seems obvious that this reverses the situation. The new system is now in the most favorable condition for ferrite network formation upon cooling. Fig. 9 shows a section across the carburized case of the steel described in Fig. 1. It is easy to see here that the very distinct ferrite network thins out to disappearance in practically the same man-

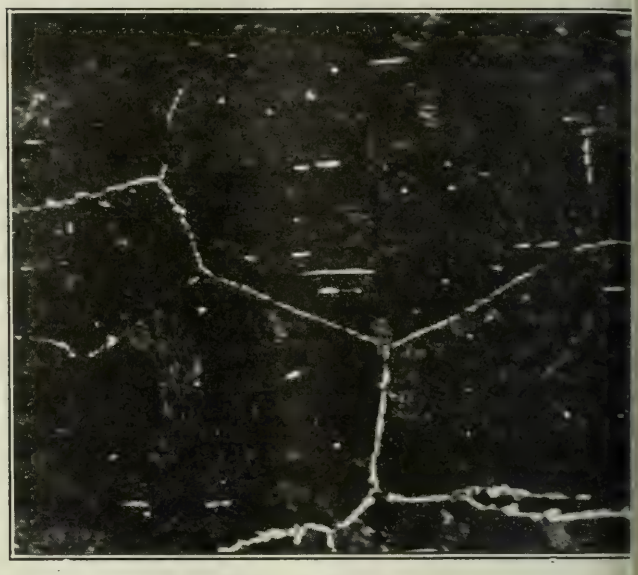

FIG. 10—DISAPPEARING FERRITE NETWORK OF STEEL SHOWN IN FIG. 9. × 100

ner as does the cementite network on the hypereutectoid side. There is no suggestion of random dots at isolated points. Fig. 10 illustrates this still more distinctly.

Fig. 11 shows the typical structure of a coarse-grained hypoeutectoid steel which has been held above the transformation range for some time and then air-cooled. Evidently the process has resulted in the formation of a primary network of ferrite, but, because of the fairly rapid cooling, migration from the interior of the grain was hindered so that excessive supersaturation finally expelled ferrite to cleavage planes between crystals to some extent, and this produced the characteristic fringes on the network. Ferrite separation is never complete in a steel cooled in this manner.

It seems reasonable to conclude that Giolitti's dot ferrite formation is largely the result of the influence of scattered non-metallic inclusions in a nearly normalized steel. His steel is stated to be "a well-made, clean steel and to be free from non-metallic inclusions, but it is well known that even the best grades of open-hearth iron or steel that can be produced contain multitudes of these minute bodies, scattered throughout the mass. Inclusions in good steel are minute and easily obscured by etching, but their influence upon segregation depends upon chemical characteristics rather than upon size, as already stated. It seems a fairly safe conclusion that the majority of ferrite "islands" found in pearlite grains in any steel are due to segregation of this character

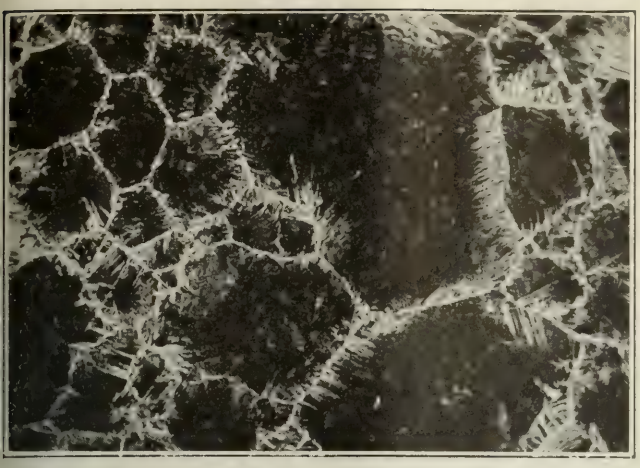

FIG. 11—AIR-COOLED HYPOEUTECTOID STEEL AFTER LONG ANNEALING. × 50

That the inclusion is not always seen in the specimen prepared for the microscope is not to be taken as proof of its absence. Of course the converse is not necessarily true, but since the inclusion is frequently a very small fraction of the ferrite grain surrounding it, the chance that a random section of the grain will contain the inclusion is relatively small.

Giolitti's steel had been heated at 900 deg. C. for 1 hour. Considering the rate of migration of carbon, as evidenced by such a process as case-carburizing or by carbon shift during decomposition of austenite, it is doubtful whether, after such heating, austenite grains a few hundredths of a millimeter in diameter in a 0.62 C steel could retain a carbon content in the grain centers low enough to precipitate β-ferrite granules. This would require that just before reaching Ar_3 these grain centers should contain less than 0.45 per cent of carbon, but in any ordinary hypoeutectoid steel carbon will migrate one-half the average diameter of the ferrite grains while cooling between Ar_3 and Ar_1.

Howe's assumption that ferrite is rejected to austenite grain boundaries in cooling steel, so vigorously attacked by Giolitti, does not involve any assumption of permanency of grain sizes and forms. On the contrary, such influences as coalescence of small austenite grains above A_3, constantly shifting temperature gradients and disturbances caused by non-metallic inclusions produce a state of unrest and continual shifting of high- and low-carbon areas, so that new grain systems are produced upon each reheating. But when this state is finally interrupted by cooling past Ar_3, ferrite will be rejected first where its concentration is highest and where disturbances produced by soluble impurities are first felt. This should give rise to a network structure, bounding austenite grains in general, but with its location modified by inclusions, whose influence can never be eliminated entirely. In addition to this network, certain ferrite grains will nearly always appear within pearlite, where zones of segregation due to inclusions or to other causes are too far from the low-carbon borders to cause a shift of the ferrite network.

Anomalous Behavior of Nickel and Manganese

In the second paper upon the subject of inclusions (to which reference has already been made) it was shown that nickel and manganese, migrating into carbon steel, resemble many of the other elements in inducing ferrite segregation in the regions thus invaded. This is an effect that at first appears to be inconsistent with the property usually attributed to these metals of lowering the transformation points of steel. If the temperature represented by Ar_3, for a steel of given carbon content, is thus lowered, one would ordinarily interpret the action as that of increasing the ferrite solubility in austenite. In a steel containing segregated nickel or manganese it would then appear reasonable to expect that ferrite would separate in these centers of contamination last, instead of first, as the steel cools, which would then leave them in pearlite grains. This is directly contrary to the observed facts.

We are unable to explain this apparent anomaly upon the basis of any direct experimental evidence, but we offer the suggestion that the localized ternary alloy produced by the invading metal, existing in direct contact with the binary solution, produces a system analogous to that of two dissimilar and immiscible solvents containing a common solute, in which the distribution ratio is not unity. Considered as the solvents in question, of course neither the iron-nickel nor the iron-manganese alloy is immiscible with iron above A_3, but the comparatively low mobility of manganese and nickel has the same effect as immiscibility, except in the case of protracted heat-treatments. If we may suppose that the distribution ratio for carbon in the two solvents (iron and iron-nickel or iron-manganese) is such as to cause a recession of carbon from the region invaded by the added (or segregated) metal, the transformation point of the system in this region will be the resultant of two opposing effects: (*a*) Lowering, primarily due to the formation of the ternary alloy, and (*b*) raising, due to the diminished carbon content. It is conceivable that the latter effect may be more pronounced than the former, the net result in a cooling steel then being that the system existing at centers of contamination will be the first to reach Ac_3 and that ferrite will be generated first in these regions.

This hypothesis is offered with some degree of hesitancy and it is to be regarded at present as merely suggestive and as subject to possible revision in the light of data yet to be obtained. The first part of the assumptions involved, having to do with the distribution ratio of carbon, is substantially the same as that offered by Stead to explain the effect of segregated phophorus. In his paper on the effect of phosphorus upon ferrite crystallization (*loc. cit.*) Stead reasoned that the "solid solution pressure" of carbon is lowered by the presence of phosphorus, with the result that carbon recedes from the regions of phosphorus segregation, the low-carbon austenite breaking down upon cooling, before the main body of the steel has reached its own transformation point.

Conclusions

It is believed that the influence of non-metallic inclusions upon ferrite segregation in slowly cooled hypoeutectoid steel is principally due to the fact that the inclusions are centers of contamination for the steel mass rather than to any connection between dissolved gases and the state of oxidation of the inclusion. The development of colored halos surrounding many of the inclusions of a polished steel or iron section, and of similar rings when such a section is treated with antimony tartrate solution, indicates the correctness of this assumption. Howe's hypothesis with respect to ferrite genesis is regarded as being correct, except for steels during their first cooling from the liquid state.

Dry Lime-Sulphur and Sulphur Dust Explosions

By Paul W. Edwards
Assistant Development Engineer, U. S. Bureau of Chemistry

PRACTICALLY any combustible dust will explode with violence, under favorable conditions, when mixed with the proper proportion of air and ignited by a flame or spark.[1] Investigations have been made by the Bureau of Chemistry of several recent explosions during the manufacture of dry lime-sulphur, an insecticide, and the grinding and collecting of powdered sulphur. Six men were seriously injured in one explosion in a plant grinding and collecting powdered sulphur.

Dry Lime-Sulphur

The following spray-drying process is used in an insecticide plant: The lime-sulphur solution is pumped from an adjoining plant to a large steel storage tank and it is then sprayed into the drier house. This drying chamber is approximately 18 ft. wide by 12 ft. deep by 12 ft. high, and below it are three hoppers equipped with a screw conveyor for collecting and discharging a large part of the dried product. Hot air, heated by means of a direct oil-fired furnace, is used as the drying medium. The products of combustion and the air used for drying are mixed and passed through a cyclone separator for the purpose of separating from the hot-air current incompletely burned particles of oil or carbon before they reach the drying chamber. Laden with dust, the air leaves the drying chamber through the sheet-metal ducts connected with the inlet of the suction-filter type collector, from the outlet of which the connection is made to the fan which induces the flow of air.

The dust collector consists of several vertical cylindrical compartments arranged side by side, each containing twelve bags for the collection of the dust. These bags are suspended at their closed ends at the same height in the compartment and are so spaced as to provide ample air channels between the individual bags and between the outer bags and the wall of the compartment. Metal rings are attached to the bags at intervals throughout their length, to keep the bags from collapsing during operation.

The dust-laden air entering near the bottom of the collector is compelled to make a turn in coming into the open lower ends of the bags. This has a tendency to make the heavier particles of dust drop into the hopper at the bottom of the collector. The bags are made of a special porous cloth suitable for holding the dust and permitting the purified air to pass through into the surrounding compartment. While the dust is being collected, the air enters the lower end of the bags, passes through the cloth and out to the fan. During the process of cleaning, a valve on the top of the collector opens, permitting a counter-current of air from the fan exhaust duct to pass from the outside to the inside of the bags and thence into the adjoining compartments. At the same time the bags are shaken violently several times. This cleaning process takes place in each compartment successively about every 2½ minutes.

Fires and Explosions

The first fire is thought to have started in the drying chamber, after the plant had been in operation for about 6 hours. The second fire occurred in the drying chamber after the plant had been in operation for 6 hours. The third fire, accompanied by an explosion, or explosion accompanied by fire, occurred after the plant had been in operation and seemed to start in the upper effluent duct. This fire occurred after a continuous run of 78 hours, during which period a large quantity of product had accumulated in the drying chamber and in the upper and lower effluent ducts, where the air velocity was not sufficient to keep the dry product in suspension. After the plant had been in operation for 61 hours, then idle for 28 hours, during which period the accumulation of the dry powder was permitted to remain in the drying chamber, and had again been put in operation for a short time, the fourth fire occurred.

The fifth fire or explosion evidently started in the dust collector, as it was confined entirely to the dust collector and the duct work connecting the dust collector and the fan, the return air duct from the fan to the dust collector, and the discharge duct from the fan through the ventilator on the roof of the building.

Cause and Prevention

It is reasonably certain that the first and second fires were caused by particles of burning oil or carbon from the combustion chamber. The combustion chamber was elevated and placed in a direct line with the main air intake trunk of the drier and it was known that particles of burning oil or carbon from the combustion chamber were entering the drier. The color of the product at that time was changed to a greenish hue, owing to the carbon which it contained. After these fires occurred a cyclone dust collector was installed between the combustion furnace and the drying chamber to remove the fine granular particles of carbon, and the finished product no longer has the greenish hue which it had before the cyclone collector was installed.

The causes of the third and fourth fires and of the first and second explosions have not been definitely determined. They may have originated from any one of the three possible sources: First, discharge of static electricity; second, sparks from oil-burning furnace; third, friction sparks due to presence of steel, wire nails, bolts, etc., in the conveyors. The presence of hydrogen sulphide and a chemical reaction generating enough heat to ignite the gas was considered a probable cause. It proved, however, to be an improbable rather than a probable cause.

This dry lime-sulphur has the following approximate chemical composition:

	Per Cent
Calcium polysulphide	75
Calcium thiosulphate	5
Free sulphur	8
"Inert" ingredients	12

L. J. Trostel, in the dust explosion laboratory of the Bureau of Chemistry, found that a 75 mg. sample of this dry lime-sulphur generated a pressure of 5.7 lb. per sq.in. when ignited in a 1,500-c.c. flask, as compared with 12.7 lb. per sq.in. for cornstarch, 11.2 lb. per sq.in. for wheat flour, and 10.1 lb. per sq.in. for Pittsburg standard coal dust. The ignition point of dry lime-sulphur was found to be between 275 and 300 deg. C. The ignition point of sulphur is 261 deg. C.,[2] and of hydrogen sulphide 364 deg. C.[3]

This would seem to eliminate the theory that the explosion was caused by the ignition of hydrogen sulphid

he ignition temperature of which is higher than that f either dry lime-sulphur or pure sulphur. The gen-ral opinion is that the fifth fire was caused by a static park. Everyone concerned was particularly interested n the cause of this fire, because it occurred in the dust ollector, a number of which are already installed in he starch, milling and other industries. It is of vital mportance that the hazard of explosions and fires be educed to a minimum in this equipment.

Dr. W. A. D. Rudge[4] has shown that any dust blown n a cloud imparts a charge of static electricity on each ust particle, the polarity and size of the charge depend-ng upon the chemical composition and fineness of the aterial. Sulphur and the sulphides when blown in a loud carry very strong charges of positive static elec-ricity. Since this particular grade of dry lime-sulphur ontained about 75 per cent of calcium polysulphide and per cent of free sulphur, it was concluded that a static harge of high potential must be accumulating on the ags of the filter type dust collector, owing to the fact hat large quantities of dry lime-sulphur were being lown from the drying chamber to the dust collectors.

Some preliminary readings were made with an elec-rometer to determine the difference of potential be-ween the filter bag and the shell of the collector which ad been thoroughly grounded. In some readings the tatic voltage exceeded 20,000 volts. It was found that y grounding one of the rings of the filter bag through copper wire, the static voltage would be decreased o 3,300 volts. The manufacturer had placed steel chains rom one end of the filter bags to the other, and ad attached both ends to the shell of the collector as means of grounding the filter bags. As a grounding edium the chain was very inefficient, owing to the igh resistance between links of the chain and to inade-uate contact with the bags. Under the circumstances would appear that the high electrical resistance of the ain was a fortunate condition; otherwise, static arks would have passed from the filter bag to the chain a very dusty atmosphere, causing explosion or fire.

Tests for Static Electricity

To obtain additional information on static electricity rmation and to devise definite methods of control, a mplete test was made on a similar equipment used in the manufacture of starch (See Table I). In compartment *A* the filter bag was not grounded and the wire to the electrometer was connected to the bag at a point midway between rings. In compartment *B* the bag was grounded with braided copper wire attached to all rings and to the top and bottom of the shell of the collector. In compartment *C* the bag was grounded with braided copper wire, sewed to the seam of the filter bag and both ends of the wire were thoroughly grounded to the shell of the collector.

The results of these tests showed conclusively that bags not properly grounded carried a high-voltage static charge while in operation, this voltage in some cases evidently exceeding 25,000 volts. In compartment *B*, where the grounding wire was attached to the rings of the filter bag, the charge was not completely carried off, a maximum of 5,000 volts being recorded in the last test. In compartment *C*, where the grounding wire was sewed to the seam of the bag, however, the bag was completely grounded. The electrometer in each of the six tests did not register any voltage.

A very interesting phenomenon was observed in the two cases where the filter bags were not thoroughly grounded. The instant the counter-current of air stopped flowing, the static charge would increase gradually until the bag started to shake, then drop to approximately 2,000 volts and remain there until the counter air current came on, at which time it would immediately drop to zero. This would seem to indicate that the charge which each particle of dust carried was not deposited on the bag, but was retained by the starch. In the sixth test, the wire to the electrometer was attached to one of the rings of the bag which was not grounded in compartment *A*. In this case the average reading was over 10,000 volts, showing that a high difference in potential existed between the ring and shell of the collector.

TABLE II—STATIC VOLTAGES NOTED ON DUST COLLECTORS IN DRY LIME-SULPHUR FACTORY

	A Chain in Stocking	B Chain in Stocking	C Wire Sewed On Bag	D Wire Sewed On Bag	E Chain in Stocking	Remarks

D—Braided copper wire sewed to bag along seam. Wire to electrometer connected to bag at a point midway between first and second rings and on side opposite to seam.
E—Steel chain through center of bag grounded to shell of collector. Wire to electrometer connected to steel chain.

[4] *Phil. Mag.*, vol. 23, p. 852 (1912), and vol. 25, p. 481 (1913).

A complete test was then made on the equipment used in the manufacture of dry lime-sulphur (Table II). These tests were made on one bag in each of five different compartments and under nine different conditions or phases of operation. In compartments *A*, *B* and *E* the test was made with a steel chain through the center of the bag. This was the method that had been used to ground the bags. In compartment *C* the braided copper grounding wire was sewed to the bag along the lengthwise seam, and both ends of the wire were grounded to the shell of the collector. It was known that the shells of all the collectors were thoroughly grounded. The wire to the electrometer was connected to the bag at a point midway between bottom of bag and the lower ring, and on the opposite side of bag from ground wire. In compartment *D* braided copper grounding wire was sewed to the seam of the bag and the wire to the electrometer was connected to the bag at a point midway between the first and second rings and on the opposite side of the bag from the ground wire. The wire to the electrometer in compartment *E* was connected to the steel chain.

No static charges were observed under the first four conditions of test—namely, when the plant was not in operation, when cold air was blown through the whole system, when air at 120 deg. F. was passed through the system and when air at 173 deg. F. was passed through the system. In test 5, where spraying had begun but the collectors were not shaking, static charges were observed on bags inadequately grounded by means of steel chains. In test 6, when the collectors were shaking, the static voltage increased almost instantly to a maximum of 5,000 volts on a bag which was inadequately grounded. It will be noted, however, that no static charge was registered on bags which were grounded with braided copper wire sewed to bag. In the seventh test, as soon as the door at the bottom of collector was opened, the electrometer registered a violent deflection over the graduated scale of the electrometer. This voltage was estimated at between 20,000 and 30,000 volts. In compartments *C* and *D* the ground wire carried off all charges. The remaining tests were repetitions of the preceding tests, for which they served as a check.

These results proved conclusively that under certain conditions extremely high static charges were generated and that these charges can be entirely eliminated by properly grounding the filter bags in the dust collectors.

SULPHUR DUST EXPLOSION IN EXPERIMENTAL GALLERY

Probably the most interesting phenomenon observed while making the tests was the fact that dry lime-sulphur builds up its static charge in a manner directly opposite to that of starch. In collecting dry lime-sulphur, a very small charge was observed when the bags were not shaking, but as soon as the shaking started it immediately built up to 5,000 volts in the bags which were insufficiently grounded with chains. When the door at the bottom of the collector was open, the voltage on these bags built up instantly to probably 20,000 or 30,000 volts, which is the reverse of the action of static charges on bags which were collecting starch dust.

Some tests were made to determine why the static charges on the filter bags collecting dry lime-sulphur did not build up gradually in the same manner that the static charges built up when collecting starch. A small installation similar to the dust collectors described was made. The filter bags were made from the same material as those used for collecting dry lime-sulphur and starch. The bags were insulated from the duct. The powdered lime-sulphur was passed through this collector at a constant rate and it was found that a static charge built up gradually to a maximum of 4,800 volts. The same condition was noted when a starch was used instead of dry lime-sulphur. It will be noted that the building up of the static charge when using dry sulphur in this test was similar to the way the charge built up in the starch collectors, and the reverse of the conditions observed in the dry lime-sulphur collectors. Since it was impossible to duplicate the static conditions as found in the dry lime-sulphur plant, it seems very probable that the difference in conditions was caused by the grounding chain used in the collectors at that plant. It was also discovered that dry lime-sulphur readily attacked the braided copper grounding wire. It is recommended that aluminum, brass, lead or steel grounding wires be used instead of braided copper wire.

Sulphur Dust Explosion

A disastrous explosion occurred recently during the collecting of powdered sulphur in the grinding section of a chemical plant. In this explosion six men were seriously injured. The equipment for grinding and the separation of the different sized particles of sulphur had been designed to operate continuously. Owing to the fact that several fires had occurred in the grinder, the grinder was operated only part of the time and the ground sulphur was bagged. The grinder was then stopped and the ground sulphur was dumped into the suction type pneumatic separating system. The sulphur was passed through a cyclone dust collector, where all particles less than 200 mesh were removed. The rest of the sulphur was carried to a filter type dust collector, where it was removed.

According to a number of workmen, the explosion occurred at the bottom of the filter type dust collector. The explosion propagated through one section of the filter type dust collector, then through the main trunk into the cyclone collector, which was completely destroyed. The explosion propagated from the cyclone collector through the trunking system to the point where the sulphur was being fed into the main trunk, at which point several feet of trunking were destroyed. An investigation showed that one end of the screw conveyor under the filter bag dust collector had become loosened. The probable cause of this explosion was the rubbing of the loose end of the conveyor on the metal jacket which produced sparks that caused the initial explosion. The explosion may have been caused by

static sparks discharged from the bag of the dust collector to the shell or hopper of the collector, and this initial explosion may have also loosened one end of the screw conveyor.

The photograph shows a sulphur dust explosion in the experimental gallery of the Bureau of Mines at Pittsburgh, Pa.

To prevent dust explosions caused by static electricity, it is essential to ground thoroughly all equipment on which charges of static electricity may be generated or accumulated. There are on the market several very efficient static detectors which can detect a difference of potential as low as 300 volts. These are valuable not only to detect static charges but also to make certain that the charges are being carried off after the equipment has been grounded.

Leaching Copper Ore With SO_2

A FEW years ago members af the Bureau of Mines experiment station at Tucson, Ariz., under the direction of C. E. van Barnevelt, made some tests on carload shipments of mill tailings and crude ores from that vicinity, having in mind the possibility that leaching by SO_2 might be utilized to increase the copper recoveries. So much success attended their efforts that the Miami Copper Co. built a 100-ton SO_2-leaching plant which was operated intermittently during 1919 and the early portion of 1920 under the personal direction of a member of the Tucson station staff. The feasibility of SO_2-leaching on copper oxides, carbonates and finely disseminated metallic copper was fully demonstrated. Certain silicates of copper occurring in the Miami ore in the form of a dilute solution of copper silicate in quartz proved quite refractory. Sulphuric acid appeared to dissolve these silicates much more readily. The SO_2-leaching plant at Miami was closed at the end of February, 1920.

When the Bureau of Mines entered the copper-leaching field the New Cornelia leaching plant at Ajo was in operation. The designers of this plant took advantage of all the accumulated knowledge on the subject of sulphuric acid-leaching and copper-refining practice and utilized the best available engineering ideas to design and build a 5,000-ton leaching plant for the treatment of their oxidized ore. Difficulties developed in the operation of the plant, attributable to soluble impurities in the ore, principally iron. An intermediate reduction process was installed to reduce the ferric iron to the ferrous condition. This alleviated but did not cure the trouble, and there is still a considerable loss of electric current. However, the New Cornelia plant was considered not only a commercial success but a decided advance on former practice. The recovery of copper ranges between 80 and 85 per cent. Three-quarters of the copper recovered is electrolytic copper and the remainder cement copper.

Coincident with the experimental work at the Miami Copper Co.'s mill, the Inspiration Copper Co. erected a 30-ton experimental sulphuric acid-leaching plant. The two mines adjoin and the ores are very similar. The Inspiration ores have the advantage over New Cornelia ores in that the amount of soluble iron is negligible. The Inspiration research staff did not venture afield outside of known practice. They did, however, take full advantage of available knowledge on the subject, with the result that they greatly simplified procedure and worked out what appears to be a highly efficient and economical sulphuric acid-leaching process. Decided advance was made in electrolysis. The absence of impurities in the ore permits the use of a very low electrolyte containing around 1 per cent copper, as against 3 per cent copper at New Cornelia. Furthermore, it was found possible to strip the discard solutions by electrolysis, thus avoiding the necessity of precipitation on iron, the entire product being electrolytic copper.

The great improvement of Inspiration results over New Cornelia results interested the Miami Copper Co. to the point of deciding to undertake similar experiments on its ores, with this modification: It was proposed to leach finely ground ore (48 mesh) as against coarse ore ($\frac{1}{4}$ in.) at Inspiration. This involved investigating the possibilities of filtration of acid pulp, and it was decided to close down experimental work on SO_2 leaching. The Miami sulphuric acid experimental leaching work has not been brought to a conclusion, though the experimental plant is temporarily closed.

In the meantime a small-scale pilot drum has been constructed at Tucson which has been developed to the point where it permits very nice control of all the variable factors. The apparatus not only gives qualitative results but gives a very dependable quantitative index. Recently, a decided advance has been made in the dissolution of the hitherto refractory silicates so that the SO_2-leaching process compares favorably with the best sulphuric-acid leaching results reported on these ores.

In 1920 the Arizona Copper Co. erected a 25-ton plant at Cliffton for leaching copper ores with SO_2. This plant began operations on June 1, 1920, and was closed down on April 15, 1921, in conformity with a rigid policy of retrenchment which resulted in closing all the Clifton operations. The Clifton work to date has fully demonstrated the applicability of SO_2 leaching to these ores. The average extraction by SO_2 about equals extractions obtained on parallel sulphuric acid work. On ores having high acid-soluble gangue content, SO_2-leaching results are particularly favorable. Former sulphuric acid-leaching tests on this material indicate a consumption of 8 lb. of acid per pound of copper recovered, equivalent to an acid cost of 4c. per pound of copper. It is estimated that the ratio of sulphurous acid (H_2SO_3) to sulphuric acid (H_2SO_4) required is 1.5 to 1 and that sulphurous acid can be made by roasting local concentrates, at about 0.06c. per pound, which is practically one-tenth the cost of sulphuric acid figured at $10 a ton. The reagent cost in SO_2 leaching would therefore be only 15 per cent of the reagent cost in sulphuric-acid leaching.

Manufacture of Salt in 1921

Census reports show a decrease in the activities of the establishments engaged in the manufacture of salt during 1921 as compared with 1919. The total value of products reported for 1921 amounted to $32,539,107, and for 1919 to $37,513,821, a decrease of 13.3 per cent. There were corresponding decreases in the number of persons employed and in the amount paid during the year for salaries and wages, but there was a slight increase in the cost of materials. Michigan, the leading state in the industry in 1921, produced 31.3 per cent of the total value of products in that year.

The combined output of all establishments was approximately 66 per cent of the maximum capacity, based upon a demand requiring full running time.

Synopsis of Recent Chemical & Metallurgical Literature

Inclusions and Ferrite Crystallization in Steel

Experiments with an open-hearth rail (analysis: C 0.55, Si 0.06, P 0.014, S 0.13, Mn 0.85 per cent) are recorded by E. G. Mahin.[1] Microscopic examination showed a banded ferrite structure, with many inclusions thought to be manganese sulphide. A cupric reagent also shows excessive phosphorus banding. This steel, when quenched from above the transformation range, showed uniform martensite—evidently slow cooling is necessary for the accumulation of ferrite, a conclusion verified by quenching samples which were furnace-cooled to various temperatures in the transformation range. The first ferrite to appear borders inclusions. However, inclusions and their ferrite shells are located indiscriminately within and without phosphorus bands.

Another sample heated for 3 days at 1,100 deg. C. under fusible glass revealed neither ferrite nor phosphorus banding in transverse or longitudinal directions. The heat-treatment coarsened the grain enormously, but did not affect the location and shape of the inclusions, nor the fact that they were still surrounded by ferrite.

Mahin concludes that while phosphorus is largely responsible for the existence of ferrite bands after ordinary heat-treatment, as held by Stead in several papers before the British Iron and Steel Institute, this is certainly not the reason for the persistence of ferrite shells about the inclusions, remaining even after long heating under carbonizing conditions.

To substantiate his hypothesis that this persistent structure was due to traces of the inclusions (or the products of the reaction which formed it) existing in a small volume of the surrounding steel, Mahin and Hartwig conducted further experiments.[2] A bar of rolled carbon steel containing 0.53 per cent of carbon was cut into disks 1 in. thick. These were drilled with ⅛-in. holes, using no lubricant. Clean rods, slightly oversize, of various metals, were then driven into these holes, and the plugged disk heated in a closed muffle at 850 deg. C. for 7 hours, cooling in the furnace. Alloys such as aluminum bronze, white metal, die-casting alloy, stellite, high-speed steel, manganese steel, chromium steel and nickel steel were used for plugs. Heat-treatment always produced a band of ferrite of greater or lesser thickness in the carbon steel at the junction. The conclusion is set forth that certain chemical elements of the high-alloy insert diffuse across the junction, enriching the carbon steel in that immediate neighborhood and so disturbing the solubility of carbon in austenite that ferrite precipitates in those impure portions somewhat above the normal recalescent temperature. This first ferrite to appear acts as a nucleus of crystallization and attracts a considerable mass of ferrite, forming subsequently.

Oxidation is held to have no influence on this decarbonized ring for several reasons. Ferrite production seems to be a minimum where contact between plug and carbon steel is poorest. The insert is never decarbonized. Furthermore, the action is too extensive to be referred to the minute amount of oxygen which could be retained. (In fact, pearlite grains reach the borders of actual cavities found at the junction, any carbon removed by gas being apparently replaced by diffusion.) Likewise, a high-phosphorus steel plug will produce a high concentration of phosphorus in the carbon steel, as can be shown by Stead's reagent. Finally, some inserts have given no ferrite bands.

That diffusion is easily possible across the junction is shown by the fact that a plug of Armco ingot iron shows a ferrite band on the sheath and pearlite at the plug.

Finally, in another paper,[3] Mahin and Brewer show that the electrode potential of the ferrite shell is 0.471 volt, while a corresponding value for ferrite in the unaffected body of the carbon steel is 0.522 volt. This is further evidence that the shell is more impure than the main body.

Doherty Washer-Cooler as a Water-Gas Condenser

In a paper presented at the 1922 convention of the American Gas Association at Atlantic City, F. W. Steere, of Detroit, Mich., described the use of the Doherty Washer-Cooler as a water-gas condenser. The Doherty Washer-Cooler method of direct condensation he defined as the process of cooling gas by bringing it in direct contact with its own recirculated condensate, the heat from the condensate being removed before recirculation. The apparatus required is a gas-tight tower with nozzles and connections, a spray-header for distributing the recirculated liquor, grids for bringing about contact between the gas and the liquor, a continuous tar and liquor overflow, a pump for recirculating the liquor, and cooling coils, or other means, for removing the heat from the recirculated liquor.

The gas to be cooled enters the washer-cooler tower at the hot gas inlet and passes upward through the grids in direct contact with the recirculated liquor. This recirculated liquor, after cooling, is sprayed over the grids at the top of the tower and runs by gravity over the surface of the grids to the bottom of the tower, where it is collected in the reservoir in the base.

In the theoretical ideal machine, the recirculated liquor in the base of the tower would be raised to the temperature of the incoming gas, and the gas at the outlet of the tower would be cooled to the temperature of the recirculated liquor at the top of the tower. Local conditions determine how close to these figures it is practical to go.

Data Required for Washer-Cooler Design

The success of the washer-cooler depends on the accuracy with which every part is designed and proportioned for the particular problem in hand. There is no such thing as a standard plant. This is obvious from the varying nature of the conditions encountered in every locality. The tendency in designing gas-works equipment is usually to "play safe." This invariably results in an unbalanced plant and an excessive charge for power and maintenance. Gas saturated with water vapor contains a known quantity of heat at all temperatures and the removal of this heat from the gas and its subsequent dissipation is all susceptible to very accurate figuring.

To determine the maximum demand on the washer-cooler, it is essential to have the data on two conditions—

First, The demand on the plant during the period of highest cooling water temperatures.

Second, The maximum hourly demand on the plant.

With these points determined, it is possible to design a condensing plant which will reduce the temperature of the gas to the lowest temperature possible under prevailing conditions.

Saturation Temperature

The real problem in cooling gas is not in cooling the gas itself, but in removing the heat carried by the water vapor. It is of the greatest importance that fairly accurate information be available on the water vapor saturation temperature of the gas to be cooled. Observations indicate that the saturation temperature of water-gas rarely exceeds 185 deg. F.

In water-gas plants it is found more suitable to locate the washer-cooler tower after the relief holder and get the benefit of the atmospheric cooling resulting from the high temperature in the relief holder. The importance of this is evident because 22,400 B.t.u. must be removed per 1,000 cu.ft. of gas in reducing a saturated gas from 19[illegible] to 185 deg. F. This is almost as much heat as must be removed in cooling

1,000 cu.ft. of gas from 160 deg. down to 90 deg. F.

Another advantage of placing the washer-cooler tower after the relief holder is obtaining a uniform flow through the condensing system without the variations resulting from the intermittent nature of the water-gas process.

Washer-Cooler Tower

The diameter, or cross-sectional area, of the washer-cooler tower cannot be figured until the design of the grids is determined. The space in the tower which is occupied by the grids reduces the gas capacity or the available cross-section of the tower to the extent of their volume. The grids, for this reason, should have the lowest possible volume in proportion to their surface.

Properly designed board grids have been found most effective for use in the washer-cooler tower. The grids must be constructed to have sufficient mechanical strength to support their weight after becoming waterlogged and to eliminate the possibility of their squashing over and closing off the gas passages. The bottom edges of the grids should be serrated to insure a uniform distribution of the cooling liquor throughout the entire height of the machine. The importance of keeping the entire surface of the grids uniformly wetted cannot be overemphasized, as dry surfaces will tend to accumulate solid matter.

With ¼-in. grids spaced ½ in. apart, the washer-cooler tower should have a minimum cross-sectional area of 1 sq.ft. for each 8,300 cu.ft. of gas passed per hour. A vertical height of 30 ft. of grids is about the minimum that can be used to bring about a complete heat transfer between the cooling liquor and the gas and at the same time thoroughly scrub the gas. These figures do not apply to volumes less than one-half million cubic feet per 24 hours, nor for handling gas through extreme temperature ranges.

Distributing Liquor Over the Grids

Since the gas outlet is at the top of the washer-cooler tower and the cooling liquor is introduced at the top, any tendency to fog the liquor as it enters the tower will result in an excessive carrying over of the liquor with the gas. The best design of spray header distributes the liquor over the entire cross-section of the machine as nearly as possible in the form of a rain, the larger the drops the better. The nozzles delivering the liquor should be placed below the level of the gas exit.

Cooling Coils

The first factor to be determined in cooling coil design is the rate at which heat is transferred through the walls. This, of course, depends somewhat on the design; but in any design the laboratory figure for the rate of heat transfer is higher than the figure which should be used for commercial operation. Experiments lead us to believe that a heat transfer of 1 B.t.u. per minute per square foot per degree of mean temperature difference is a safe figure for commercial operation. It must be noted that this figure is based on the mean temperature difference and not on the average temperature difference.

Cooling coil stacks may be either single-pipe or double-pipe. The liquor usually passes through the coils in single-pipe stacks and the cooling water over the outside. Double-pipe stacks are made by putting one pipe inside the other, with the liquor to be cooled passing through the annular space between the pipes. The cooling water flows through the inner pipes and over the outer pipes. The double-pipe stack is not recommended for water-gas cooling, as it is more liable to stoppage and not as accessible as the single-pipe stack.

In the ideal stack, using the countercurrent principle of heat transfer, the cooling water is raised to the temperature of the liquor to be cooled as it leaves the bottom tube, and the liquor is cooled to the temperature of the cooling water. If the stack is too high, the lower pipes of the stack are inoperative, as this temperature equilibrium has been attained before the cooling water reaches the bottom of the stack. If the stack is not high enough, the cooling water leaves the stack before it has been raised to the temperature of the incoming liquor.

The heat can also be taken from the recirculated liquor by passing it over the cooling coils instead of through the cooling coils. This requires an extra pump unless the cooling coils can be placed at a sufficiently low elevation so that the hot liquor can run over the coils by gravity. The cooling water is then run through the coils and this heated water, under pressure, can be utilized for other purposes without repumping.

When the cooling water passes over the coils, there is also a cooling of the cooling water resulting from evaporation. Under conditions of low humidity, this atmospheric cooling may amount to as much as 25 per cent of the total cooling. It should not, however, be taken into account in the calculations for those parts of the world where high humidity and high atmospheric temperatures may occur simultaneously.

Atmospheric Cooling

The heat may be extracted from the cooling liquor by atmospheric cooling. This may be done either in an atmospheric type of cooling tower, in a forced draft type of cooling tower, in a cooling pond or in a combination of these schemes which may fit in with local conditions.

With cooling coils, a washer-cooler tower with the smallest possible cross-sectional area should be always used. This means a lower first cost, and at the same time insures the highest possible heat transfer efficiency. With atmospheric cooling, a larger and more expensive washer-cooler tower is desirable and in many cases necessary. The reason for this is obvious when we recall that a given quantity of liquor is required to wet the grids irrespective of the quantity which may be required to take up the heat in the gas. If the cross-section of the washer-cooler tower is increased, thereby increasing the quantity of liquor required to wet the additional grids, the liquor at the bottom of the tower will be at a proportionately lower temperature, because there is more of it to absorb the same quantity of heat. The mean temperature difference, therefore, between the liquor to be cooled and the cooling medium is correspondingly lower. When cooling coils are used, this condition is serious, as there is a direct relation between the cooling surface required and the mean temperature difference. With atmospheric cooling of the recirculated liquor, the lower temperature of the liquor to be cooled is an advantage. This follows from the fact that as the temperature range through which the liquor must be cooled increases, the expense of the equipment and cost of power rapidly increases.

With atmospheric cooling, there is no cooling water required from any outside source. From this standpoint, atmospheric cooling has a distinct advantage. On the other hand, the mist, saturated with tar and oil vapors, which is given off during the process of atmospheric cooling, carries about the plant and the surrounding district. In spite of the most careful baffling, this at times is very disagreeable. If the plant is located in a settled district, this may result in serious complaints from the neighborhood.

On plants where cooling water is not available in sufficient quantities and where direct atmospheric cooling of the recirculated liquor is objectionable, a very satisfactory combination can be effected by using an atmospheric cooling tower for removing the heat from the water used over the coils. The only cooling water required with this arrangement is the make up to replace that lost by evaporation and windage.

One very interesting fact becomes apparent from a study of any condensing and cooling problem—that is, the key of the design of the entire condensing system is the design of the grids in the washer-cooler tower. This is obvious when we recall that the cross-sectional area of any tower is determined by the proportion between the area occupied by the grids and the free gas passages. The size of the tower, in turn, determines the quantity of recirculated liquor required to wet the grids. The quantity of recirculated liquor determines the temperature to which this recirculated liquor will be raised after passing through the tower. The temperature of the recirculated liquor directly determines the mean temperature difference available for cooling. The mean temperature difference is the factor which determines the number of stacks of cooling coils required. If atmospheric cooling is used, the same argument applies to the range through which the liquor must be cooled.

In conclusion, I might add that pos-

sibly the best proof of the fundamental soundness of this method of cooling and condensing gas is the fact that a great many plants have replaced their tubular condensers with washer-coolers, but I have yet to hear of a washer-cooler being replaced by a tubular condenser.

Rapid Sorting of Alloy Steels

M. Gallibourg presented a note before the French Academy of Sciences (Feb. 6, 1922) in which he proposed to distinguish between steels of equal hardness by measuring their contact e.m.f. against iron. A small pot of mercury, preferably kept at 120 deg. C., is needed. An ordinary galvanometer, potentiometer or delicate millivoltmeter is also required. Electrolytic iron wire is used for leads, the end of one being immersed in the mercury bath, and the end of the other welded to a water-cooled clamp.

Each piece of steel is first tested by the Brinell method and sorted into groups of approximately equal hardness. Every piece of steel of hardness 190-210, for instance, is then tested for contact e.m.f. by clamping each individually in the fixture and immersing the other end into the mercury bath. The latter acts as a heating medium and also establishes a perfect electrical connection. Within a few seconds the electrical indicator reaches equilibrium and a reading is taken. Steels having equal hardness and equal e.m.f. are quite certain to be of the same chemical composition; as a matter of fact, heat-treatment, which affects the hardness greatly, makes little or no change in the electrical characteristics. Only in rare instances would it be necessary to retest a group of steels having the same hardness and contact e.m.f. Such retesting should be done after normalization.

The Influence of Iron on Copper and Copper Alloys

In delivering his address as the chairman to the members of the Birmingham local section of the British Institute of Metals, of Oct. 10, Dr. F. Johnson took as his subject "The Influence of Iron on Copper and Copper Alloys." The following is a summary of the address:[1]

Copper—Iron up to 0.5 per cent deoxidizes, toughens and strengthens copper, even in the presence of arsenic. It is very detrimental to electrical conductivity and a very small quantity makes the metal paramagnetic and unsuitable for using in galvanometers. Copper is capable of holding about 3 per cent iron in solid solution.

Alpha Brass—There appears to be an overwhelming weight of opinion in favor of keeping the iron content low—say, 0.1 per cent—for the reasons that it increases (*a*) the casting difficulties, (*b*) the power required for mechanical operations, (*c*) the annealing costs, (*d*) the corrodibility. For special purposes—e. g., articles required to be stiff and springy—the addition of iron is advantageous, but it need not exceed 1.0 per cent for these purposes. Advantage might be taken of the influence of iron in raising the annealing temperature of cold-worked alpha brass to increase the convenience of the low-temperature annealing processes for the removal of internal stresses of cold-worked material. A slightly higher temperature of annealing would mean a shortening of the annealing period—an advantage in works practice.

Alpha + Beta Brass—Iron appears to serve a very useful purpose indeed in large castings of this type, particularly in reducing the grain size and improving the strength and toughness. The indications appear to be that the beneficial action is greater in the case of brasses in which the beta phase is in excess, and that 1 per cent need not be exceeded.

Beta Brass — The grain size is reduced, but no improvement in mechanical properties appears to accrue to castings. An improvement, especially in ductility, has been found to occur in the case of hot-forged and rolled bars. This may be due to retardation of recrystallization during the hot-working process.

Nickel Brass (Nickel Silver) — The addition of iron has been specially recommended for cutlery stock and extra hard springs.

Copper - Aluminum (Aluminum Bronze)—Iron up to 4 per cent has been found to be very beneficial in reducing grain size, retarding crystal growth and facilitating the production of die castings.

Admiralty Gunmetal—Iron up to 1 per cent does not appear to be detrimental if correctly alloyed. The mechanical properties are enhanced under such conditions, in the case of small chill castings.

In most of the alloys examined, the limit of solid solubility occurs at less than 1 per cent iron. In brass there are two forms in which the iron exists in excess of that entering into solid solution—viz., (1) As free iron-rich crystallites, globular or cruciform in shape. These are pale blue, but turn black when etched. (2) As very minute uniformly distributed dark-etching particles. As a rule, the beneficial influence of iron ceases at the degree of concentration at which the free crystallites appear.

[1] Reported in *The Engineer*, Oct. 20, 1922, p. 412.

Heat-Treatment of Gray Cast Iron

It has often been proposed to anneal gray iron castings in order to relieve internal strains and to machine more easily. Aging 2 months or more in the weather is also resorted to—corrosion will eat through hard spots on the skin at the same time.

J. E. Hurst has presented an article in *The Engineer* (July 4, 1919) in which he concluded that Fe_3C in cast iron containing more than 1 per cent Si gradually decomposed at 550 to 600 deg. C., regardless of the amount of cementite originally contained. Lower silicon irons were found to be very stable.

E. Piwowarsky, in *Stahl und Eisen* (Sept. 28, 1922), took a gray cast iron (combined carbon 2.68, graphite 0.5, silicon 0.07), remelted part with steel scrap (resulting in combined carbon 1.0, graphite 1.5) and another part with 1 per cent Ni. To soften these irons they had to be quickly heated a little above Ac_1 (800 to 825 deg. C.) and cooled at 2 deg. per minute through the transformation—i.e., down to 735 deg. C. Annealing below Ar_1 did not graphitize the carbon.

A second paper in the same issue was written by E. Schütz. He used castings containing (after reheating) 3.1 per cent of graphite, 0.5 per cent combined carbon and 2.3 per cent Si. Such castings varied in Brinell hardness from 126 to 155, surface to center. Cementite in the eutectoid pearlite started to decompose in these castings after 24 hours at 500 deg. C., and the reaction was completed and hardness uniformly reduced to 130 after 3 hours at 650 deg. C., or 24 hours at 600 deg. C.

Importance of Alloy Steels

A striking illustration of the present importance of alloy steels is given in production statistics recently issued by the American Iron and Steel Institute. Despite an extremely low tonnage for the whole industry in 1921, the relative amount of alloy steel remained very close to its record 1919 figure.

TABLE OF PRODUCTION OF STEEL INGOTS AND CASTINGS AND OF ALLOY STEEL INGOTS AND CASTINGS IN THE UNITED STATES. (000 omitted)

	Total Steel, Gross Tons	Alloy Steel, Gross Tons	Alloy Steel of the Total, Per Cent
1909.....	23,955	181	0.75
1910.....	26,094	567	2.17
1911.....	23,676	481	2.03
1912.....	31,251	792	2.53
1913.....	31,300	714	2.28

Book Reviews

THE MINERAL INDUSTRY DURING 1921. VOL. XXX. Edited by *G. A. Roush* and *Allison Butts*. Cloth, 6¼ x 9½ in. 895 pp. McGraw-Hill Book Co., New York, 1921. Price, $10.

It is a favor to the reading public not familiar with it to be informed regarding the "Mineral Industry." It is the only publication of its kind. Its object is the compilation annually of reviews of the progress during the preceding year in the different fields of mining and metallurgy. Authorities in various lines, after the calendar year has been completed and the statistics and data in the various geological and governmental reports are authentic, contribute articles on the general and economic phases of the industry, thus bringing together under about fifty headings, arranged alphabetically, accurate data on the different subjects, which include Abrasives, Fuels, Metals, Jewels, Precious Stones, and covering these both from the production and economic standpoint. The volume is international in its scope.

Engineers, economists and statisticians accept the publication as a matter of course and regularly add it to their library; but because of the fact that it is issued annually and the first cost seems high, its circulation is relatively limited. It is most probable that there are a large number of people interested in metallurgical products who would greatly appreciate such a book if its merits were brought to their attention; in fact, the writer showed this volume to one of the principal purchasers of one of our precious metals who had never seen it and his criticism was most favorable.

The 43 contributors to the volume include professors, statisticians, consulting engineers, government employees and authorities along various lines, the most of them contributing regularly.

The volume is necessarily published somewhat late after completion of the calendar year, as the governmental statistics must be complete and authentic and also because of the time required by the contributors to arrange the subject matter.

The value of a reference book containing accurate statistics and the possible errors that might occur from using figures containing preliminary reports as to data is illustrated by the fact that the writer has on his desk an annual publication of metal statistics published early in the year and for which a supplementary report was issued in July, correcting certain annual production figures to the extent of about 6 per cent.

The last volume of the "Mineral Industry" is of great interest at a time when industrial conditions are becoming more normal; it shows the lessening of production of metals and materials which were produced in more than normal quantities during the war and also shows the increased production of industrial materials used in times of peace. We look forward with interest to the publication of the volume covering the year 1922.

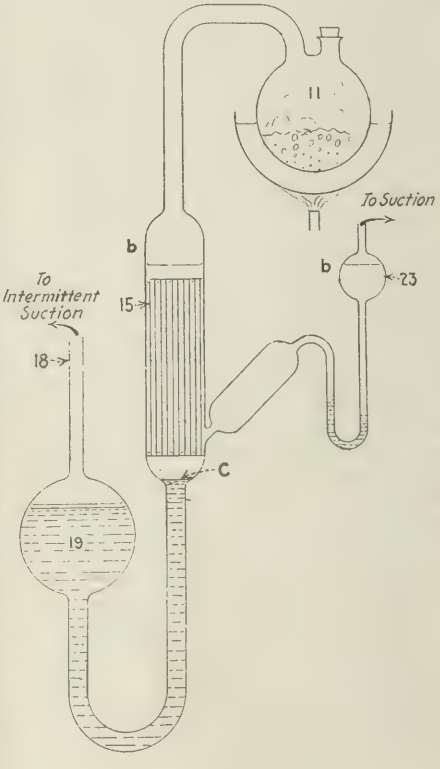
MARSHALL S. WALKER.

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Separating Aqueous and Other Vapors From Solids and Fluids — In this patent Dr. Otto Maass, of Montreal, points out that the absorption of water by dehydrators, particularly sulphuric acid, is relatively slow under normal conditions, but if the dehydrators are spread out in thin films, the absorption is extremely rapid. An illustration is given herewith of the laboratory apparatus which was used in this work. The liquid to be evaporated is placed in vessel 11, and vessel 19 contains the dehydrator, in this case sulphuric acid. The principle of operation consists of applying suction at both 18 and 23. First, this causes a diminution in the pressure inside the vessel, then atmospheric pressure is let in at 18, and the liquid rises to a point approximately equivalent to *b* in the diagram. Suction is then applied again at 18, and this draws the liquor down to a point approximately *C*. This acts simply to evacuate the system completely and to saturate the walls and surfaces in vessel 15 with the sulphuric acid. Pressure then becomes sufficiently low so that evaporation takes place at a very low temperature. This is facilitated by the absorption of the vapor evolved in vessel 15 by the sulphuric acid. The process is repeated as long as desired. The application in industry would consist in the evaporation of substances which require low temperature of evaporation due to their easy decomposition in atmosphere—for example, H_2O_2. (U. S. Pat. 1,417,618.)



Method of Conducting the Ammonia-Soda Process—Edward E. Arnold and Palmer St. Clair have conceived the scheme of using liquid ammonia and liquid carbon dioxide as cooling media instead of water in ammoniating and carbonating towers. They object to the complicated water piping systems necessary to effect cooling of the ammonia and carbon dioxide absorption processes in the ammonia-soda process for sodium carbonate. A great deal of water has to be used, and in summer, in many localities, this is unsatisfactory, as the water supply is apt to be fairly warm. By introducing liquid ammonia and liquid carbon dioxide, they would materially cut down the quantity of cooling liquor necessary, because the latent heat of vaporization of the two substances would be equivalent to a relatively large quantity of water in producing equivalent quantities of available heat.

An advantage lies in the fact that leaks in the cooling system would have no harmful effect. Take, for example, the cooling of the carbonating towers with liquid carbon dioxide. Suppose there were a small leak in the cooling system. It would mean the escape of small quantities of carbon dioxide gas into a tower in which carbon dioxide gas was being absorbed. The patent has been assigned by the authors to the Nitrogen Corporation of Providence, R. I. (U. S. Pat. 1,423,510. July 25, 1922.)

Making Low-Boiling Hydrocarbons—Benzol, toluol and other low-boiling hydrocarbon oils are the products obtained from various permanent gases in the process patented by Clive M. Alexander and assigned to the Gulf Refining Co. Natural gas, still gases and various other gases made by heating oil, etc., are submitted to a high temperature, specified as 500 to 100 deg. C. and under a pressure of 50 to 100 lb. A molecular rearrangement takes place to form vapors of the low-boiling or liquefiable hydrocarbons. The patentee states that catalysts may or may not be used in his process. Their presence, however, is often useful, since they lower the necessary heat and pressure. Most of the common metals have the power of catalyzing the operation. Copper, nickel, cobalt, iron, etc., or their oxides may be used. In order to present a larger surface for action and to distribute the heat more uniformly, the heating zone may be provided with some inert carrier material, such as diatomaceous earth, saturated with a solution of one of the catalysts. (1,411,255; April 4, 1922.)

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, Eng.and.

Synthetic Tanning Agents—Soluble tanning agents are produced by condensing at least two molecules of an aromatic hydroxy compound with one molecule of formaldehyde, using an alkaline condensing agent, sulphonating the product with one to two molecules of sulphuric acid and then partly neutralizing. Crude cresol is given as an example of the aromatic hydroxy body; oxides, hydroxides, carbonates or bicarbonates of alkali and alkaline earth metals, ammonia or alkaline salts such as sodium acetate are referred to as condensing agents; while as neutralizing agents, oxides, hydroxides or carbonates of alkali and alkaline earth metals, or ammonium hydroxide or carbonate, may be employed. Instead of formaldehyde, its polymers or compounds giving rise to it may be used; also the condensation may take place at ordinary or increased pressure.

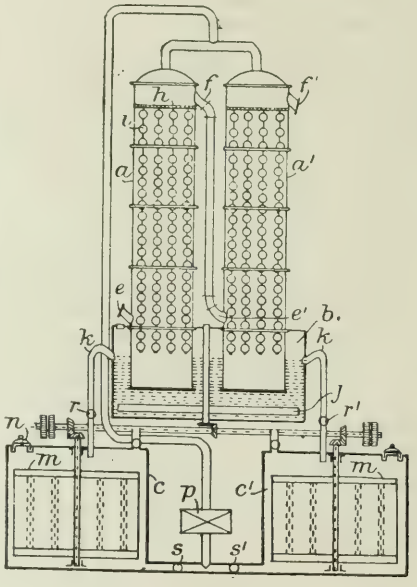
A separate specification covers a modification of the process, in which the sulphonation is followed by condensing the sulphonated resin with an aldehyde and an aromatic compound containing one or more sulphonic acid groups alone or in combination with hydroxyl or halogen groups before neutralizing.

The sulphonated aromatic compound used in the second condensation may comprise the sulphonated resin of the first condensation; and the aldehyde in the second condensation may be formaldehyde or its polymers, acetaldehyde or its polymers, trithioacetaldehyde, aldol or crotonaldehyde. For the partial neutralization, oxides, hydroxides and carbonates of alkali and alkaline earth metals, zinc and magnesium, and ammonium hydroxide and carbonate may be used. Crude cresol is given as the example of the aromatic hydroxy body employed in the first condensation; and crude cresol sulphonic acids and crude α- and β-naphthalene sulphonic acids are given as examples of the sulphonated aromatic body of the second condensation.

Both patents are assigned to McArthur & Co., Ltd., of Liverpool. (Br. Pats. 182,823 and 182,824. R. B. Croad, G. E. Knowles. Aug. 30, 1922.)

Artificial Silk—In the manufacture of artificial silk from solutions of cellulose acetate, nitrocellulose or other ester, ether or derivative of cellulose by a dry-spinning process, the spinning solution is composed of the cellulose ester and a mixture of one or more low boiling point solvents or liquids and a solvent or solvents of high boiling point, and the filaments or threads are drawn out during the spinning, the high boiling point solvent retarding the solidification of the filaments and facilitating the drawing out. Larger jet orifices can be employed for the production of a given denier. The use as high boiling point solvents of tetrachlorethane and like toxic chlorine derivatives is excluded. Suitable high boiling point solvents are acetone alcohol, acetylacetone, diacetone alcohol and cyclobutanone; such solvents are used in an amount not greater than 50 to 100 per cent of the weight of the cellulose ester. Acetone and methyl acetate are suitable low boiling point solvents, but the latter may be in whole or in part replaced by organic diluents of similar volatility. (Br. Pat. 182,166. H. Dreyfus, London. Aug. 23, 1922.)

Chlorates and Hypochlorites—Relates to the manufacture of chlorates and hypochlorites, more particularly the former, of calcium or magnesium by chlorination of the corresponding hydroxide, and to the preparation of potassium chlorate therefrom. A dilute suspension of calcium or magnesium hydroxide is chlorinated, to which fresh material is added from time to time, until a solution of chlorinated products of 60 to 64 deg. Tw. is obtained. For



example, milk of lime containing about 50 grams $Ca(OH)_2$ in suspension is prepared in the mixer *c*, agitated by the stirrers *m*, and, the valves r^1, s^1 being closed, is pumped by pump *p* to the top of the towers *a*, a^1, through which it descends into the vessel *b*. A distributing plate *h*, together with ebonite-coated glass balls *i*, serves to distribute the liquor and expose a very large surface to the action of the chlorine, while at the same time preventing the deposition of solid matter in the towers. Chlorine, of a suitable concentration, passes through the towers, entering at *e*, e^1 and leaving at *f*, f^1, as shown. The liquid in the vessel *b* is agitated by the stirrer *j* and returns by the siphon *k* into the mixer *c*. Thence it is again circulated through the towers. As the chlorination proceeds, fresh lime is periodically introduced into the mixer *c* through the inlet *n*. The temperature during chlorination is kept below 70 deg. C. by using diluted chlorine, and, if necessary, by adding water to the liquor in the mixer *c*. The product of the process, a solution of calcium chlorate and chloride, and possibly hypochlorite, of 60 to 64 deg. Tw., is pumped from the mixer and filtered. If it is desired to prepare potassium chlorate, potassium chloride, in an excess of 2 per cent over the theoretical amount, is added, and the bulk of the chlorate permitted to crystallize at atmospheric temperature. The mother liquor is diluted, if necessary, until there is present preferably 45 to 50 grams calcium chloride in 100 grams of water, when the liquid may be cooled to —20 deg. C. to separate further quantities of potassium chlorate, without simultaneous separation of ice or of calcium chloride. It is convenient to connect the outlet f^1 of the apparatus to a similar apparatus in which comparatively fresh milk of lime is being treated. Then when the liquor circulating in the first unit has been completely chlorinated, the valves *r*, *s* are closed, and the partly chlorinated lime in the second unit is pumped into the mixer c^1 for treatment as described above. Preferably, however, the conveyance of liquor is avoided by reversing the order of the units, and conducting the chlorine first to the second unit and then to the first unit, the mixer c^1 of which contains fresh milk of lime. The chlorine mains are provided with connections which permit this procedure, the connections not being shown in the diagram.

The process may be applied to the production of concentrated hypochlorite solutions. (Br. Pat. 183, 671. M. Wilderman, London. Sept. 20, 1922.)

Urea—In the manufacture of urea by forcing a mixture of ammonia and carbon dioxide into an autoclave, the gases are brought to the necessary pressure by expelling either or both of them from solutions capable of giving them off, by means of heat. By way of example, a concentrated solu- of ammonium carbonate or carbamate is forced into a heated column, the gas mixture produced passed through a cooler at about 110 to 150 deg. C., and the condensate run into an autoclave, where it is heated at 130 to 150 deg. C. until the conversion into urea no longer proceeds. The autoclave may be filled and discharged either at intervals or continuously, or the process can be carried out with single charges when the column is replaced by a pressure-resisting vessel. The unconverted gases are expelled from the urea solution and used, together with fresh gases, to saturate the exhausted liquid from the column for further use. The gaseous ammonia and carbon dioxide may be generated in separate columns —for example, from aqueous ammonia and sodium or ammonium bicarbonate solution respectively—or one of the gases may be forced into the autoclave by means of a compressor. (Br. Pat. 182,331. Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine. Aug. 23, 1922.)

Tantalum—The use of tantalum for vessels used in the preparation, distillation or concentration of hydrogen peroxide is covered. (Br. Pat. 184,153 not yet accepted. Chemische Fabrik Weissenstein Ges., Carinthia, Austria Sept. 27, 1922.)

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields
Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Few Changes Likely Under Elastic Tariff—Blackstrap Error Adjusted

THE TARIFF COMMISSION began active operation of the flexible tariff section of the new act Nov. 9 when it received preliminary reports from its advisory board on fourteen applications for changes which had been filed with it and acted upon five of them. No rates of major interest are involved in the first fourteen preliminary reports, it was announced.

Thus far, seventy-two applications for changes in the new tariff act have been filed with the commission. Of these, twenty seek changes in classifications, which naturally would affect duties. Fifty-two applications seek direct changes in figures in paragraphs of the act, twenty-nine asking decreases and twenty-three asking increases.

Chemical Schedule Protested

The chemical schedule is affected by the second largest number of applications, ranking next to the agricultural schedule, with the sundries third. Five of the applications in the chemical schedule ask that the basis of valuation for assessing duties be transferred from foreign value to American value. This cannot be done under the act unless the Tariff Commission should find and report to the President that a change of 50 per cent upward on the basis of foreign valuation would not equalize the cost of production.

None of the chemical applications was included in the reports of the advisory board first submitted. Definite announcement of the commodities or products affected by the applications has not been made and will not be until the commission decides whether to proceed with an investigation or to dismiss the application.

It is expected that the commission will start an investigation before Dec. 1 of some commodity among the applications in order to get the full machinery of the act under way and to determine the value of the section and its workability.

Blackstrap Muddle Adjusted

The Treasury Department has issued instructions to customs collectors to collect an additional duty of one-sixth of a cent per gallon on blackstrap molasses testing above 52 per cent total sugars only on the percentage above 52. This order clarifies the situation created by a previous interpretation of the molasses paragraph of the new tariff.

An order along the lines originally proposed by the department would have created a prohibitive rate on blackstrap testing between 52 and 56 per cent total sugars and would have meant that before such molasses could be imported for use in stock feed it would have to be diluted to bring it below 52 per cent, which would have meant heavier tonnage in this class of imports and consequent heavier expense to the importers. The situation arose through failure of the tariff conferees to make an insertion of three words in the molasses paragraph, which was reframed by special resolution after the tariff bill had been adopted by both houses of Congress.

The Treasury's decision is to interpret the paragraph in accordance with the obvious intent of Congress and to keep the clause in question in harmony with the remainder of the paragraph.

Perplexing Problems

Several perplexing questions with regard to the imposition of the so-called flexible provisions of the new tariff act remain to be decided by the commission. One of the most important is whether the tariff body is authorized to change rates in the case of imports which have no counterpart in American production. The guide laid down by Congress for rate adjustment is the difference in the costs of production at home and abroad, but manifestly in such cases such differences cannot form the basis for a decision.

Potash From Kelp Established as Commercial Enterprise

Not only is there every indication that the kelp-potash plant established by the Bureau of Soils for experimental purposes at Summerland, Calif., will be a permanent commercial enterprise, but plans already are being made for its enlargement. The plant was purchased by the United States Kelp Products Co. after it had been operated for experimental purposes by the Bureau of Soils since 1917. Potash is now being produced at the plant at the rate of 5 tons a day. The principal product, however, is kelp char, which is in much demand as a substitute for bone-black as a bleaching agent.

J. W. Turrentine, who was in charge of the plant for the Department of Agriculture and who has been in charge of its operations since their inception, has returned to Washington to take up anew his research work on potash.

Deterioration Tests on Calcium Arsenate

Quality Not Affected by Age, According to Bureau of Chemistry

No practical possibility exists of change in the chemical composition of calcium arsenate during storage. This conclusion has been reached by the Bureau of Chemistry after exhaustive studies on the keeping qualities of calcium arsenate. The detailed description of the tests and the analyses on which the conclusions are based are being printed and will be available in December.

Commercially Important

The question of whether or not calcium arsenate deteriorates during storage has been a controversial one. This point is of special importance to the Federal Insecticide and Fungicide Board, not only because the material must be carried over from year to year by farmers and dealers but because the information is necessary in the enforcement of the insecticide act. If material which analyzes improperly is found in the possession of a cotton farmer, it must be known whether or not there is any possibility of this material having been of correct composition when it left the factory and having deteriorated since that time. Under the insecticide act, prosecutions can be made only when the material is shown to be of improper composition when it entered interstate commerce.

Test Conditions

In making these tests certain lots of material were held in storage at the laboratory of the insecticide board for 6 years and have been analyzed at intervals throughout that period. Other special tests were made of material which had been exposed to extreme conditions during storage. In one series of tests barrels were left standing partly open, totally exposed to the weather, for 11 months. During that time the physical character of the material was altered by rain, but the chemical analysis remained practically the same.

Stocks of calcium arsenate were purchased from eight of the principal manufacturers, selected as representing the principal methods of production. In each case one barrel of the material was left intact in the original package, while the remaining stock of each manufacturer was divided among ten different types of containers, representing all the types used commercially for shipping calcium arsenate.

Midgley Addresses New York A.C.S. Section

Describes Development of Anti-Knock Compound for Gas Engine and Theory of Gaseous Detonation

Before a large and enthusiastic audience in Rumford Hall, on Friday, Nov. 10, Thomas Midgley, Jr., described the now well-known work of the General Motors Research Corporation on "Gaseous Detonation and Its Control." It was substantially the same address which he delivered before the Pittsburgh meeting of the American Chemical Society. The apparatus for the demonstration of the efficacy of anti-knock compound which was used at Pittsburgh was lacking, but the deficiency was more than made up by the delightfully informal and extemporaneous delivery.

Improving Fuel Economy

Mr. Midgley began at the beginning and described the efforts made by different departments to increase the efficiency of internal combustion engines as applied to the automobile. The mechanical engineer would improve the mileage per gallon of fuel by decreasing the gear ratio, but would cut down the potential acceleration of the car and decrease its power on hills. The expert in thermodynamics would increase the compression ratio, but this causes knocking. It looks as if a practical solution of this problem must come from the chemist.

With the aid of his ingenuous revolving chart, the speaker described his conception of the mechanism of internal combustion and gaseous detonation. He derived mathematical expressions showing the relation between the pressures on both sides of the explosion face. The equation contains a constant term. If this constant term could be increased or decreased by the use of a catalyst or, in other words, the reaction velocity changed, it would be possible to use a high pressure in the cylinder without causing knocking. "Wouldn't it be a beautiful scientific achievement," he asked, "if, having derived these equations and shown how a catalyst might change the constant term, we should then simply find the proper catalyst? As a matter of fact, that was not how it was done. We found the substance first, and made up the mathematics afterward."

Story of Development

Early in the investigation of motor fuels there was a theory, which, although it proved short lived, was a good theory—not because it was true, but because it led to results. The theory was that fuels which gave gaseous detonation did so because they were not completely volatilized in the explosion chamber. It was believed that as the gas was compressed, the boiling point of the suspended globules of fuel rose, and although the temperature was continually rising at the same time, it never got high enough for the liquid globules to ignite. Acting on this theory, it was decided to add some coloring matter to the fuel so that it would absorb radiant energy and upset the thermal equilibrium. "We went to the stockroom," said Mr. Midgley, "and asked for an oil-soluble dye." "They did not have any, so they handed out the first thing that came to hand. It happened to be iodine. We made up some brown, some purple and some black gasoline, tried it out, and found that it did not knock. The theory was proved. The same day we got some oil-soluble dye and made up gasoline of the same color with it. It had absolutely no effect on the gaseous detonation. The theory was shot to pieces.

Cut and Try Research

This, however, was the beginning of a series of tests using every element and compound which was available in the laboratory stockroom. Aniline proved to be much better than iodine. Later, tellurium proved to be better than aniline. Up to this time, however, none of the anti-knock compounds tried were commercially practical on account of their high cost and their relative scarcity. Sufficient evidence, however, had been collected by this time to enable the investigators to present the efficacy of various compounds by reference to the periodic table and it was as a result of this line of investigation that lead tetra ethyl was tried out and found to be superior to anything that had been tried before as well as being a commercial possibility."

The talk aroused a great deal of discussion in which Wilder D. Bancroft and J. C. Olsen took part. The ready wit of the speaker made the discussion most interesting and amusing, and on the whole, it was the most human and entertaining meeting that has been held in Rumford Hall for many a day.

Chicago Ceramic Society Plans Annual Meeting

Program Covers Enamel Defects, Smelting Furnaces, Production Planning, Proposed Ceramic Engineering Course

Anticipating a record attendance for its sixth annual meeting, which will be held on Saturday, Dec. 2, at the Morrison Hotel, Chicago, the Chicago section of the American Ceramic Society is planning a meeting with numerous discussions on subjects of live interest to those who will attend.

Briefly, the program now scheduled is to include a discussion on defective enamels by B. T. Sweely, Cribben-Sexton Stove Co. Mr. Sweely spent several months in Washington recently on enamel research work and is well qualified to give a very instructive talk on sheet steel or cast-iron enameling. H. E. Davis, ceramic engineer of Northwestern Terra Cotta Co., will describe a new type of smelting furnace of interest to both enamel and terra cotta manufacturers. A representative from a firm of industrial engineers which has done work in the ceramic industries on glass, enamel, pottery and brick plants will speak on some phase of production. A representative of the Chicago Board of Education will tell of the efforts being made to establish a course in ceramic engineering in the new Crane Junior College just completed. The establishment of such a course would be of great value to the ceramic industries in the vicinity of Chicago, and manufacturers of that section ought to be vitally interested in the discussion that will take place at this meeting.

The event will open with a luncheon at the Morrison Hotel at 12:30 Saturday, Dec. 2, the program following immediately after luncheon. All persons interested in ceramics are cordially invited to attend this meeting.

New Italian Ambassador An Accomplished Engineer

Caetani Studied and Practiced in America—Distinguished Service in War Won Him Decorations

The appointment of Gelasio Caetani a member of the Chamber of Deputies of Italy, as Italian Ambassador at Washington has been received with interest by American engineers, among whom Prince Caetani has many friends.

He was graduated from the School of Mines of Columbia University in 1903 and went West, working as a miner, trammer, timberman and mill-hand at Stratton's Independence mine in Colorado, at the Treadwell in Alaska and at the Bunker Hill in Idaho. He carried through some important projects for the Bunker Hill & Sullivan Co. and later opened offices in San Francisco as a consultant. As a member of the firm of Burch, Caetani & Hershey, Mr. Caetani was engaged in important jobs, mostly in Montana.

Brilliant War Record

At the outbreak of the war Don Gelasio returned to Italy, and was made a Captain in the First Regiment, Royal Engineers. Before the end of the war he was a Colonel. The feat which won world-wide fame as an engineering exploit was the blowing up of the top of the Col di Lana, which destroyed an Austrian fort and opened the way for the Italian army through the Cordevole Pass in the upper Trentino.

After the war he combined business with politics and was elected to the present Chamber as a Nationalist. According to letters received by his American friends, the new Ambassador was one of the first of the Roman nobles to embrace the Fascismo—in fact, he is said to have enrolled himself among the original ninety Fascisti organized as a Roman cohort in 1920.

The choice of Prince Caetani as Ambassador is considered an admirable one, because of his familiarity with American affairs. The date of his departure for the United States has not been fixed.

Coal Commission Gets Down to Business

Dr. Smith Resigns as Director of Geological Survey to Serve on President's Committee

The fact-finding machinery being set up by the President's coal commission is now taking definite form. While the commissioners expect to get much of their information from the broad conclusions from outstanding men engaged in coal production, distribution, wholesaling and retailing, a vast amount of data must be collected by a technical staff. That portion of the work which deals with costs of production will be under the immediate direction of David L. Wing, whose title is to be expert investigator. As the work progresses, Mr. Wing will gather other statistical facts.

C. E. Lesher, editor of *Coal Age*, has been drafted to direct the engineering investigations which the commission will conduct. Coal specialists from various bureaus will be transferred to the commission.

Associations Will Co-operate

Assurances of co-operation have been given by each national association connected with the coal business. A statistical program is being worked out which it is believed will cause very little dissension. It is being arranged so that those engaged in the business can furnish the information in the way it is carried on their books. President Stephens of the Retail Coal Merchants' Association has conferred at length with members of the commission, and so has a committee representing the public utilities. More formal conferences are in contemplation. The one with the retailers is to be held the latter part of November. There is every evidence that the commission will have the whole-hearted co-operation of the whole coal business.

Where statistical and other information is furnished by one branch of the industry, arrangements are being made whereby the other branches concerned and the commission itself can check the figures as they are being compiled. In this way it is hoped to compile statistical data the correctness of which will be admitted by each branch of the industry.

Smith Resigns From Survey

Since the government's law officers decided that Dr. George Otis Smith may not lead a double official life, it became necessary for him to resign his position as director of the United States Geological Survey. After having discussed the matter personally with the President, Dr. Smith presented a formal resignation in which he, among other things, said: "Some plans I have had in mind for the betterment of the Geological Survey's contributions to the public are unfinished, even after my 5¾ years as director. I therefore regret this break in my work, yet while I hope I may have an opportunity for further service with the Geological Survey, I appreciate so keenly the importance to the nation of the task you have intrusted to the coal commission that I am willing to make any sacrifice needed to enable me to devote all my energies to that work for the next 11 months."

In his reply and in a statement issued at the White House, the President explained that Dr. Smith's resignation is of a temporary character and that he will be reappointed as director of the Survey when his duties with the coal commission will have been concluded.

Personnel Generally Approved

The same provision of law bars Judge Alschuler from serving in two official positions. The President will ask Congress to make an exception in this case, but until such a law is passed Judge Alschuler will not qualify as a member of the commission. He will work with the commission, however, in an informal capacity.

The Geological Survey comes in for praiseworthy mention in the recent editorial in the Philadelphia *Public Ledger*. In discussing the coal commission, the editorial says: "The appointment of George Otis Smith was an act for which Mr. Harding cannot be commended too highly. The Geological Survey is purely scientific, non-political, magnificently efficient and brilliantly administered."

The coal commission has been endeavoring since its organization to arrange for the appearance before it of both Secretary Hoover and Secretary Davis. Other duties of these Secretaries, however, have made this impossible.

American Foundrymen's Directors Organize—Accept French Invitation

The board of directors of the American Foundrymen's Association met in Chicago Oct. 3 and completed its organization by electing C. E. Hoyt secretary-treasurer, R. E. Kennedy assistant secretary. R. A. Bull, S. T. Johnston, L. W. Olson and Fred Erb, together with the president, vice-president and secretary, will constitute the executive committee of the board of directors for the coming year. S. Griswold Flagg, 3d, of Stanley G. Flagg & Co., Philadelphia, Pa., was elected a director to fill the vacancy caused by the death of J. P. Pero.

The directors provided for a permanent board of awards, consisting of the seven last living past presidents of the American Foundrymen's Association, Inc., with the junior past president as chairman of the board.

An invitation was received from the Association Technique de Fonderie, of France, inviting the A.F.A. to join with the foundrymen's associations of France, England and Belgium in an international convention and exhibit in Paris in September, 1923. The invitation was accepted and referred to a committee to be appointed by the president, who will represent the A.F.A. and determine to what extent the association will take active part in the proposed international convention.

Discusses Human Factor in Engineering

Personnel Association Urges Active Support of Technical Colleges by Industries

Co-operation with the engineering colleges, the public schools and industries of the nation in enlarged educational effort was urged by committees of the National Personnel Association in reports presented at the closing sessions of the first annual convention of the association in Pittsburgh last week.

"The present state of engineering education is one of active flux," said the report of the committee on relations with engineering colleges, consisting of W. E. Wickenden, American Telephone & Telegraph Co., New York; F. L. Bishop, dean of engineering, University of Pittsburgh; and G. H. Pfeif, secretary, educational committee, General Electric Co., Schenectady, N. Y.

"Educators and officers of industry are agreed that the demands of civilization on the engineer are becoming broader and call for a more fundamental and less specialized form of education. Engineers have achieved brilliant success in creating the machines and structures which make modern industry possible. They are now being called upon to give equal concern to the agencies of society which utilize this material equipment."

Human Element in Engineering

The committee stressed the importance of the "human factor" in engineering, saying:

"As engineers constitute an increasingly influential group in modern industry and government, all member companies are concerned that the schools shall ground them in sound principles and equip them with sound methods in their relations to social and economic questions. There is a need that engineers shall attack these questions with the same unprejudiced, fact-finding, analytical methods that they have used with such marked success on material problems. As a balance to these dispassionate, scientific methods there is an equal need among engineers for sympathetic insight into human motives and aspirations and an understanding of the principles which underlie governmental, business and industrial organization."

Industry Owes Support

"The engineering colleges have a strong claim on the assistance of the industries in return for services rendered," continued the report. "The schools have made inestimable contributions to scientific knowledge from which the industries have profited without cost. Education has increased earning power and so has made possible the markets on which many industries depend for existence. The colleges have expended on each engineering graduate from $800 to $2,000 above all fees received. The industries profit by this and would have to provide costly substitutes for it if it were not available."

Will Pass on Merit of A.C.S. Papers Before Meeting

Industrial Division Hopes to Improve Quality of Material Submitted

In order that more time can be given to the presentation and discussion of papers delivered before the industrial division of the American Chemical Society, it has been decided to ask all who plan to give papers before this division to submit completed manuscripts not later than March 1 to the secretary of the division. The manuscripts will then be sent to reviewers. Upon favorable recommendation of the reviewers and the officers of the division, the papers will be included in the final program of the division.

It has been felt for some time that something must be done to raise the standard of some of the papers which have been given before the division. In some cases old material has been redescribed under a new heading, which often was misleading. No doubt the new method will reduce the number of papers to be presented at any one meeting, but it is felt that a few genuinely good papers followed by a sufficient time for discussion will be what most chemists desire. At the Pittsburgh meeting there were so many papers on the program that a time limit of 7 minutes was allotted, with 3 minutes for discussion. This time proved to be so short that a speaker could not present the paper in the best manner possible, and the period for discussion was so short that there was practically no attempt on the part of members to discuss the subject.

Since the spring meeting occurs at New Haven April 5 to 7 inclusive, it is necessary for members of the American Chemical Society who are planning to present papers before the industrial division to send their papers on or before March 1 to Erle M. Billings, Kodak Park, Rochester, N. Y., secretary of the division.

Belgians and Germans Dominate European Cement Market

Belgian and German cement makers have succeeded through the policy of price cutting in almost completely arresting exportation of French cement in the last 3 months, according to reports received by the Iron and Steel Division of the Department of Commerce. The factories at Boulogne-sur-Mer, the largest cement-manufacturing center in France, are capable of producing 600,000 tons annually, or about three-fifths of the total French production. Conditions in this region are typical of the situation throughout the entire industry. It is estimated that the cement industry during the last week of July was working at about 80 per cent of normal, whereas the first weeks of the month it was only working at 70 per cent.

French exporters are still shipping a small quantity of cement which they are content to sell at the cost of production.

Efforts Needed to Improve Salary Standards of Government Chemists

A determined effort is being made to convince the Navy Wage Board that chemists in the naval service should be better paid and should be differently classified. The Wage Board is now in session considering revisions in the wage scale. Under the law, wages of the employees in the naval establishments must conform with those paid by comparable private establishments. In the case of chemists, it is particularly difficult to find chemists in private industry doing work of the same character. For that reason it is particularly hard to bring before the board convincing evidence as to pay in private industry. The situation of chemists in the navy is so bad that frequently their title is changed to "master mechanic" or "powder expert" so as to make it possible to pay them enough money to retain them in the service.

Revised Gasoline Specifications Approved

The Interdepartmental Petroleum Specifications Committee announces that its latest revision of the federal specifications for petroleum products was approved by the Federal Specifications Board on Oct. 31.

The one outstanding change in the specifications is in motor gasoline, the initial boiling point being lowered to 55 deg. C. and the 90 per cent point raised to 200 deg. When the specification for motor gasoline was last amended in 1919 it was hoped that the specification would be satisfactory for at least 2 years. It has actually been in effect 3 years and improvements in the refinery practice in this period have indicated that the specification could be modified to advantage. This has accordingly been done. The specification for domestic aviation gasoline has been modified to permit the use of cracked gasoline in cases where the material is to be used within 3 months. A corrosion test has been substituted for the doctor test in the specification for mineral spirits. Grade 2 of Liberty aëro and motorcycle oil has been dropped, as this oil is not being purchased at the present time. A few minor changes have been made in some of the other specifications.

The specifications in force previous to Oct. 31 are given in Technical Paper 305 of the Bureau of Mines, and the methods adopted by the committee for testing petroleum products in Technical Paper 298. It is planned to publish the revised specifications, together with the testing methods, as Technical Paper 323, which will be issued by the Bureau of Mines as soon as possible.

The Interdepartmental Committee held an open meeting on July 3, and comments and criticisms on the specifications and testing methods were considered, and such changes as were adopted are incorporated in the revised set of specifications.

Patent Office Still Swamped

Flood of Applications and Heavy Turnover in Personnel Pile Up Work

Despite enactment by Congress last spring of a bill readjusting salaries upward in the Patent Office and authorizing twenty-nine additional examiners and twenty-two clerks for the personnel, the work of the office is no more advanced in overtaking the number of pending applications than it was a year ago. This is attributed to a steady increase in applications for patents and extensions and to increase in applications for the registration of trademarks.

With the revival of industry, the Patent Office also is having difficulty in holding experienced technical men as examiners against the inducements of private employment. While 362 examiners are authorized, approximately a dozen vacancies exist because of inability of the Civil Service Commission to supply qualified men at the salaries offered.

It was stated at the Commissioner's office that within 49 working days twenty-two examiners submitted resignations. It is figured that it requires 6 months for a new employee to become accustomed to an examiner's work, so that resignations are especially serious when they affect this staff. Also, if two resignations come in a single division, two divisions are disturbed, as one new man is put in and an experienced examiner is transferred from some other division to fill the second place. In one division the examining staff now consists of two who have been with the Patent Office 3 years, two who have been there 2 years and three who have been there less than a year.

In several weeks this year the Patent Office has cleared more patents than it has received applications. The flood of applications which set in during and after the war, however, has made it difficult to speed the work as had been hoped for. Up until Nov. 1, 32,582 first patents had been issued for the calendar year, compared with 37,885 during the 12 months of 1921, which shows a higher rate of issuance this year. On Jan. 3, however, there were 60,244 cases up for action in the office and on Oct. 31 these had increased to 70,313. The greatest activity among applicants has been along chemical and electrical lines.

Large Industrial Alcohol Distillery Incorporated

The Canadian Industrial Alcohol Co., Ltd., was incorporated under Dominion Government charter on Oct. 27. The capital of the company is $10,000,000, and the main office is at Montreal. The provisional directors are: James Shaughnessy, a son of Baron Shaughnessy, former president of the Canadian Pacific Ry.; A. R. Holden, H. J. Hague and Chilton G. Howard. No announcement has been made as to the location of the distilleries or from what the product is to be made.

Fertilizer Association Boosts Soil Improvement

States Will Co-operate With Committee —Prizes for Best Fertility Programs

Of the twenty-six states embraced within the activities of the soil improvement committee of the National Fertilizer Association, twenty-four have completed arrangements to co-operate with the organization's soil fertility program plans and a number of county agents have registered for the work. One other state is expected to join and one has declined.

In order to interest county agents in surveying their fields to formulate a definite soil fertility program, the soil improvement committee has offered to defray the expenses of eight agents who can show the best organized work along soil-fertility lines in their respective counties to attend the 1923 meeting of the American Society of Agronomy. The agents are being reached through the extension work of the state experiment stations and register both with the station and with the committee.

The territory to be covered has been divided into four sections, each of which will have two trip-winners. Agents first will submit their programs to the state station, which will select the three best. The best three from each state will be judged by a committee comprising Director S. B. Haskell, Massachusetts Agricultural Experiment Station; Dr. A. G. McCall, in charge of soil investigations, Maryland Agricultural Experiment Station; Dr. Firman E. Bear, professor of agricultural chemistry and soils, Ohio College of Agriculture, and Prof. M. F. Miller, professor of soils, Missouri College of Agriculture.

The object of the plan is to promote more intelligent use of fertilizer by studying and analyzing the results of soil experiments and interpreting these results for the fertilizer industry and the farmers. The program will be judged according to their application to the needs of the section affected and naturally will not be of uniform character.

Surplus Smokeless Powder Transferred to Department of Agriculture

The director of sales announces the transfer to the Department of Agriculture by the Ordnance Department of 5,995,474 lb. of smokeless powder located at the following points: Woodbury, 6,520,100 lb.; Old Hickory, 25,-57,239 lb.; Curtis Bay, 184,897 lb.; Pinmatol, 428,250½ lb.; Seven Pines, 639,309½ lb.; Tullytown, 4,636,552 lb.; Charleston, 529,126 lb.

This transfer, with 5,000,000 lb. previously transferred to the Bureau of Mines, Department of the Interior, disposes of the entire stock of smokeless powder reported surplus to the director of sales, with the exception of 12,312 lb. which still remains surplus and available for sale.

Tendency Toward Federation in Engineering Growing

L. W. Wallace, executive secretary of the Federated American Engineering Societies, has completed a coast-to-coast tour, during which he set in motion plans for Federation expansion, stressing the great influence exercised by the Federation since its organization about two years ago under the presidency of Herbert Hoover and evidencing this by the report of its committee on the elimination of waste in industry, as well as by the report of the committee on work periods in continuous industry and by other substantial achievements. Mr. Wallace was attentively heard by large engineering gatherings in many cities. Everywhere, he reports, engineers are recognizing the enormous potentialities for technical and public service which reside in the Federation as the instrument of expression and action of the engineering profession in America.

New York Industrial Conference

"Elimination of Waste in Industry" will be the theme for discussion Wednesday, Nov. 22, at the sixth annual New York State Industrial Conference to be held at the Hotel Lafayette, Buffalo, for three days beginning Nov. 21. Mr. Wallace will deliver the opening address at the session, his topic being "Wasteful Industrial Habits." H. F. Simmons of the General Electrical Co., Schenectady, will speak on "How to Prevent Waste of Materials." Other speakers at the conference will include Gov. Nathan L. Miller.

Hoover Reiterates Attitude Toward Metric System

While believing that the metric system can be applied to good purposes in the scientific field, Commerce Secretary Hoover has in no way altered the opinion he has expressed on several occasions since assuming his portfolio. It is his opinion that there is nothing to justify the general application of the metric system at this stage of the country's development. When productivity is important, it would be unwise "to warp the brains of the country's mechanics" in their efforts to acquire the metric system, Mr. Hoover says. He thinks much of the propaganda for the metric system comes from a single indefatigable enthusiast.

First Iron Furnace in Central Pennsylvania 130 Years Old

The first iron-smelting furnace ever operated in central Pennsylvania, located on the outskirts of State College, was marked with a tablet under appropriate dedication ceremonies on Oct. 30. The furnace was constructed 130 years ago, as set forth on the bronze tablet, given by the State Historical Commission and the department of history of the Pennsylvania State College. Former President E. E. Sparks of the institution presided at the dedication ceremony, in which the students and faculty of the college participated.

Patent Board Formulates Policies

Regulations for Handling Patents Evolved by Government Employees

With the idea of drafting regulations establishing a policy to be followed by the federal government in the handling of inventions and patents evolved by government employees and other inventions and patents acquired by the government, regular meetings are being held by the Interdepartmental Patents Board. This board recently was set up by an executive order issued by the President. Any policy proposed by this board is to be presented, through the Secretary of the Interior, to the President for his approval. The regulations also will suggest a plan whereby information concerning patents, applications for patents, licenses and other rights under patents, owned by the government, may be disseminated to all the bureaus concerned.

At the present time the activities of the board are being concentrated on the collection of data which will furnish the basis on which any policy proposed will be founded. In the past little effort has been made to co-ordinate patent policies of the different federal bureaus. As a result there has been confusion and duplication. This, the board believes, can be obviated and plans made which will permit of a more intelligent and effective handling of all departmental patent matters.

Andrew Stewart, of the Bureau of Mines, is chairman of the Interdepartmental Board. Colonel Joseph I. McMullen, of the General Staff, is its secretary. The other members are: F. G. Cottrell, Fixed Nitrogen Research Laboratory; S. W. Stratton, director, Bureau of Standards, and Harry E. Knight, Department of Justice.

Mexico Encourages Development of Naval Stores Resources

American naval stores operators, according to advices reaching Washington, are paying increased attention to the possibilities of development of the industry in Mexico. Scarcity of turpentine timber and rising costs in this country, coupled with special inducements from Mexico, are encouraging experienced American operators to consider the establishment of enterprises there. In fact, American interests already are operating on a small scale in Mexico.

The acreage of turpentine timber in that republic is known to be large. It can be obtained at very low prices. Labor is cheap and some of the Mexican states are prepared to authorize tax exemptions to encourage the industry. On the other hand, there are the drawbacks of unsettled political conditions and the difficulties of transportation. The situation, however, is regarded as being of moment to the domestic industry, the prosperity of which is dependent to a considerable extent on the retention of its foreign markets.

Standardization Efforts of Department of Commerce

While the Simplification Division of the Department of Commerce is pressing lumber, hardware and containers as immediate objectives of a major nature, it is co-operating with trade organizations representing more restricted scope at the same time and plans are being laid for new fields of endeavor in 1923.

William A. Durgin, chief of the Simplification Division, was scheduled to address the National Paint, Oil and Varnish Association on Nov. 14 at its convention in Atlantic City to further the work of standardization which has been started by that organization. The association has under way a survey of colors and of containers which is expected to lead to more economical practices.

The American Salt Producers Association also will be addressed by Mr. Durgin while he is in Chicago. This association is looking toward simplification of containers. Mr. Durgin will also speak before the American Petroleum Institute in St. Louis on Dec. 6 on the subject of the same standards for oil well supplies and materials in the different fields of the country.

STANDARDIZATION OF CONTAINERS

One of the largest subjects taken up by the division is that of containers—metal, wood and pasteboard. This affects such a large number of producers and consumers that the division has assigned a special attaché to this subject. A general conference on containers will be held in Washington under the auspices of the Department of Commerce in January, and probably will occupy a week's time.

Washington Chemists Elect Officers

At the November meeting of the Chemical Society of Washington, W. M. Clark of the Hygienic Laboratory was elected president for the coming year; J. B. Reed and H. W. Houghton were re-elected secretary and treasurer, and councilors of the American Chemical Society were elected as follows: W. W. Skinner, R. B. Sosman, R. C. Wells, W. D. Collins and F. C. Cook.

The Washington chemists will join the Baltimore section on Friday, Nov. 24, for a visit to the new refinery of the American Sugar Refinery Co. in Baltimore. A special joint dinner will be held that evening at the Engineers Club, followed by a brief technical session.

Steel Treaters Organize Classes in Heat-Treating

Under the direction of the Indianapolis Chapter, American Society of Steel Treating, arrangements are being perfected for the establishment of a local class to meet at the Arsenal Technical School for studies in heat-treating of steel. The course has been designed for employees of local manufacturers, who are co-operating in the plan, and will be closely associated with the Purdue University Extension Department. Twenty persons have signified their intentions of entering the class, and it is expected that this number will be increased to fifty.

Civil Service Openings

The United States Civil Service Commission announces open competitive examinations for junior chemist on Dec. 6, 1922. Vacancies in the departmental service, Washington, D. C., at $1,200 to $1,800 a year will be filled from this examination.

Positions in the federal classified service throughout the country and the departmental service in Washington for laboratorians—chemical, physical and engineering—are also open and will be filled from applicants who take examinations on Dec. 6 and 7. Salaries range from $1,200 to $1,500 a year.

Both the above carry the additional $20 a month bonus for satisfactory service.

Agricultural Chemists Meet in Washington

Standardization of Analytical Methods to Be Attempted—Notable Speakers

Federal and state chemists engaged in agricultural and food chemical work throughout the United States will attend the thirty-eighth annual convention of the Association of Official Agricultural Chemists to be held in Washington, D. C., at the Raleigh Hotel, Nov. 15 to 17. Particular consideration will be given at this convention to agricultural chemistry with regard to the control laws affecting food and drugs, stock feed, commercial fertilizers, and insecticides and fungicides.

One of the chief objects which the association will attempt to accomplish at this convention will be a standardization of the methods used by the various analytical chemists engaged in the work at different stations, so that the findings of one station may be comparable to those of another station. The methods devised and recommended by the association have become quite generally used, but it is hoped that there will be a still further coordination of effort effected.

PROMINENT SPEAKERS

Approximately seventy-five subjects will be discussed in the 3 days' meeting by as many different chemists covering a wide range of work. On Nov. 16 the association will be addressed by Secretary of Agriculture Wallace, Dr. H. W. Wiley, honorary president of the association and former chief of the Bureau of Chemistry, and Dr. F. P. Veitch of the Bureau of Chemistry, United States Department of Agriculture, president of the association.

Senator E. F. Ladd of North Dakota, who is a chemist and was at one time head of the chemistry division of that state and president of this association, will also address the convention.

To Close Gap in Byproduct Coke Statistics

The U. S. Geological Survey has recently been getting a monthly report of byproduct coke output corresponding to the reports received during the war. However, figures have not been available for 1919 and 1920 and the Survey is now planning to get these data so that there will be a continuity of record from 1917 on.

The Survey is urging co-operation of the industry in this matter. It is recognized that the data are of very great industrial significance not only in the coke industry itself but also to metallurgical industries and fuel users generally. An early summary of the data is promised if prompt reply is received by the Survey.

Personal

BURTON T. BUSH and M. J. SEELEY of Antoine Chiris Co., New York sailed for Europe Oct. 24 on the Aquitania. They expect to return early in December.

GASTON DUBOIS, president of Monsanto Chemical Works of St. Louis sailed Saturday, Nov. 4, on the Maure tania for a business trip to England France and Germany. He expects t return late in December.

HUGH M. HENTON, consulting engineer, of Cleveland, Ohio, has arrived a Pullman, Wash., to succeed Prof. Chester G. Warfel, who died last summer as assistant professor of mining an metallurgy in Washington State College. Professor Henton has been connected with the Case School of Applie Science and with the South Dakot School of Mines, of which he is a grad uate. At one time he was director o research for the Aluminum Casting Co. of Cleveland.

SAMUEL L. HOYT, formerly metallurgical engineer in the experimenta engineering laboratory at Nela Park Cleveland, is now in the researc laboratory of the General Electric C at Schenectady.

Dr. GEORGE OTIS SMITH has resigned as director of the U. S. Geological Survey in order to qualify logically as member of the President's Coal Commission. The responsibility for th conduct of the Survey during the nex 11 months will be in the hands of Phili S. Smith, who has been the Survey's ad ministrative geologist.

Obituary

WILLIAM D. HOWE, vice-president of the Clark Chemical Co., of Denve Colo., died recently, at the age of 69.

CHARLES J. TAGLIABUE, president an founder of the C. J. Tagliabue Manufacturing Co., of Brooklyn, died r cently.

Market Conditions

In Chemical, Metallurgical and Allied Industries

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities
Prevailing Prices and Market Letters From Principal Industrial Centers

Distribution

This General Problem Is Being Intensively Studied Now Because of the Enormous Economic Waste Bound Up With It—What Will Be the Outcome?

WE HAVE reached an efficiency in production which has never been equaled before. It is possible for us to flood the country with almost any commodity within a short time. Production is almost too efficient. Small wonder that, in company with Herbert Hoover, business men have been turning their attention to distribution and its obviously wasteful methods.

A short time ago a manufacturer asked us to estimate the per cent which his effective sales effort represented of his total sales activity. We passed. "Less than 1 per cent," he announced. "Yet my salesmen are successful according to ordinary standards and well paid." This estimate may be lower than the average, but it is qualitatively representative.

Here is a real problem! What are we going to do about it? Is it reasonable to expect better results from the better use of the present tools? Let us suppose that we redistribute advertising on a new basis, plan selling effort more effectively, retain only the most efficient salesmen, revise credit terms. Can we raise the ratio of effective selling up to a reasonable figure of efficiency?

The Danger of Generalization

Any such question must be individual and specific. Very few generalizations are possible when it comes to problems of business procedure. Take, for example, the cry which has gained considerable force recently, "Away with the middleman! Let us have direct to consumer sales! It will save millions and reduce high prices!" It must be confessed that it has a logical sound. During a recent railroad strike many freight cars destined for New York City had to be unloaded in the suburbs. We recall a fleet of five or six beautiful Packard trucks which bore an inscription something like this:

Coogan & Mooney,
Commission Merchants,
Onions Exclusively
165 X St., New York City.

It was rather an overwhelming idea. Six beautiful trucks bespeaking great prosperity, all on commission selling of onions. The prosperity of such a company argued ill, it seemed to us, for an efficient distribution machinery in modern society. Were those trucks and the profits behind them a necessary tax on society? We felt not. So we grant, then, that it looks as though there was too much middleman occasionally.

The Other Side of the Picture

A young and enthusiastic executive once said: "Away with dealers! We will market our own products!" This he proceeded to do. A live sales manager and a flock of promising salesmen were procured and a great future was predicted. At the end of the year there were no increased profits. In fact it looked very much like a loss. "Why?" groaned the young executive. The dealers marketed a hundred products. They distributed their selling overhead over all of them. Consequently even assuming that their established clientèle was of no advantage whatever, they could distribute more cheaply than the producer with his fifteen products. The moral is: Do not fall into an easy way of talking about business problems by means of formulas. The middleman is not a menace to be eliminated. In some industries he is undesirable. He is often a very salutary influence. The problem of distribution will not be solved by eliminating him.

Some Methods of Tackling This Problem

Let us consider some possible ways and means of effecting distribution economy. First, there are the conventional methods of increasing efficiency in the sales department which have already been referred to.

Study advertising mediums and redistribute advertising effort.

Co-ordinate work more effectively with advertising.

Estimate individual efficiency of salesmen or dealers.

Consider possible variations in terms of credit.

Study changes in product or packaging to attract consumers.

And many other similar studies which have to do with the structure and policy of the department.

A second and exceedingly important method, as yet little tried, has to do with a study of economic conditions in a given district or trade. At the present time a sales manager hears from his salesmen that St. Louis is dead or that the metal-working business is poor. It is becoming increasingly possible for the sales manager to advise the salesmen from his office that St. Louis will be dead for several months or that the metal-working trade will be poor in a short time. This is not by guesswork or by tips, but by business statistics.

It will remind you a little of the White Queen in "Alice Through the Looking-Glass," who screamed terrifically and nearly fainted because she was going to scratch her finger. When she did prick it on a pin, she said: "See, I told you so!" So with statistics! We shall be able to predict depressions, local and national, and this will help to decrease the inflation and make the reaction less severe.

Changes Are Inevitable

Thus the sales manager will have to be an economist as well if he is to put his department upon the highest plane of efficiency. Distribution is and will be the major problem of industry during the next decade. The prizes for the courageous will be exceedingly great. Important and revolutionary changes are certain. This does not mean that they will be consistent—they may be fundamental in industries or in individual companies and yet the composite picture reveal but slightly the fundamental changes. Advertising is bound to be vastly different, with more science, more statistics and less general chatter about reaching markets and benefits accruing. Sales will probably become in general a producer-to-consumer proposition, but the middleman will still continue serviceable, often invaluable. Sales will have to be more intelligently, more deftly, guided. It is a quantitative era in distribution, and many pet nostrums will die of old age and their propagandists will look for clerical work.

"Chem. & Met." Weighted Index of Chemical Prices

Base 100 for 1913-14

This week	158.70
Last week	157.01
November, 1921	146.82
November, 1920	240
April, 1918 (high)	286
April, 1921 (low)	140

The advance in the index number is due to strengthening in the price of cottonseed oil primarily. It indicates, however, a continued strong healthy market. Reference to the market letters confirms this and reveals a weaker market in very few commodities.

The New York Market

NEW YORK, Nov. 13, 1922.

The general tone of the chemical market remained quite steady during the past week. Actual transactions were not as numerous as in previous weeks. However, spot material remained exceedingly firm, with buyers unable frequently to purchase desired quantities. Formaldehyde continued its upward trend and consumers were forced to pay top prices. Competitive selling has practically disappeared from the market and first hands were in control of any available supplies. The feature of the week's trading was again centered around commercial white arsenic. Manufacturers have announced a new advance and importers were quoting considerably higher for shipment material. All tin commodities have been advanced, due to the higher prices for the metal. Bichromates held quite steady. Prussiate of soda showed signs of weakness and prices were much lower in several important trading quarters. The alkali market recorded very little change and prices were firmly maintained among leading producers. Acetate of lead was again advanced on account of the higher prices for lead.

GENERAL AND SPECIAL CHEMICALS

Acetate of Lead—Makers have advanced all varieties ½c. per lb. The general range is as follows: Brown broken, 10½c. per lb.; white crystals, 12c. per lb. in casks; white granular, 12¼c., and white powdered, 12¾c. per pound.

Arsenic Oxide—Spot goods have been in limited supply and small lots sold as high as 11¼c. per lb., with the range around 11¼@11½c. per lb. Shipments were strongly maintained around 11c. per lb. c.i.f. New York.

Bleaching Powder—The spot market presented a quiet appearance, but large consumers showed an interest in contract deliveries. Several sales were recorded for contract over next year at 2c. per lb. f.o.b. works in large drums. Spot quotations are held at 2c.

Caustic Potash—Imported material showed some firmness and figures were fractionally higher around 6⅝c. per lb. for spot goods.

Caustic Soda—No important change has been noted in the export market and producers are holding prices at $3.60 per 100 lb. f.a.s. The domestic demand is routine at $3.75@$4 per 100 lb., ex-store.

Cobalt Oxide—Spot material was somewhat higher and demand seems to have materially improved. Black oxide is held around $2.10 per lb., with the gray ranging around $2.35@$2.40.

Copperas—The spot market is in an exceedingly tight position. Material at the works is moving at a very slow rate and consuming demand far exceeds the spot supply. Several sales were recorded at $28@$30 per ton for spot goods. Shipment material in bulk was quoted at $21 per ton.

Formaldehyde—The market is reported firmer in all producing quarters and 14c. per lb. seemed to be the general asking figure.

Prussiate of Soda—There has been a pronounced selling pressure in this product and prices were much lower on spot. Sales were reported as low as 21½c. per lb., although the general figure was around 22c. per lb.

VEGETABLE OILS

Linseed Oil—Lower cables for the seed resulted in an easier market for the oil. The general demand was somewhat quiet and distributors showed more desire for new business, the situation being greatly in favor of the buyer. Spot oil sold around 87c. per gal. in carload lots. Foreign oil sold in a small way at 86c. per gallon.

Coconut Oil—The market was a shade higher during the week. Spot Ceylon type oil, in barrels, held around 8¾c. per lb. November-December goods, for shipment from the coast, were quoted at 7⅞c. per lb., sellers' tanks.

Corn Oil—Crude oil on spot was in very limited supply and quotations were heard around 9¾@10c. per lb.

Rapeseed Oil—Although the demand was considerably weaker than in the previous week, prices were firmly held. Spot was 77c. per gal. in barrels.

CRUDE RUBBER

The continued strong demand from leading consuming quarters resulted in a much firmer market on all grades. Sales of smoked sheets were reported at 22¾c. per lb. on spot. Most interest was manifested in deliveries over the remainder of the year. Caucho ball upper, was quoted at 18¼@18½c. per lb. First latex crepe was also higher at 22¾@22⅞c. per pound.

Some Production Statistics for Sulphuric, Nitric and Mixed Acids

Reports made by the Department of Commerce show a considerable decrease in the activities of the establishments engaged chiefly in the manufacture of sulphuric acid, nitric acid and mixed acid during the year 1921 as compared with 1919. The total value of products reported for 1921 amounted to $20,529,000, and for 1919 to $31,470,000, a decrease of 34.8 per cent. Of the thirty-five establishments reported in 1921, five were located in New Jersey; five in Pennsylvania; four in Ohio; three each in California and New York; two each in Maryland and Virginia, and one each in Alabama, Arkansas, Colorado, Connecticut, Illinois, Kansas, Massachusetts, South Carolina, Tennessee, Texas and Utah. New Jersey, the leading state in the industry in 1921, produced 27 per cent of the total value of products in that year.

The decrease in the value of products has been accompanied by decreases in the number of persons employed, in the total amount paid during the year for salaries and wages and in the cost of materials used.

The statistics for 1921 and 1919 are summarized in Table I.

Detailed statistics of production for 1921 and 1919 are given in Table II. These acids are also produced to a very considerable extent by establishments primarily engaged in the manufacture of other products: Sulphuric acid by manufacturers of fertilizers, explosives, chemicals in general, and petroleum refineries; and nitric and mixed acids by manufacturers of explosives and chemicals in general. Hence the production here reported is not to be taken as representing total production. The table shows for 1919 the percentage which the production of establishments primarily engaged in the manufacture of these acids constituted of the aggregate production reported for all industries. Corresponding figures for 1921 are not available.

TABLE I—COMPARATIVE VALUE OF PRODUCTS AND OTHER RELATED DATA IN 1919 AND 1921 FOR SULPHURIC, NITRIC AND MIXED ACIDS

	1921	1919	Per Cent of Decrease*
Number of establishments	35	39	....
Persons engaged	3,139	5,860	46.4
Salaried employees	450	899	49.9
Wage earners (average number)	2,684	4,961	45.9
Salaries and wages	$5,243,000	$10,096,000	48.1
Salaries	1,317,000	2,179,500	39.6
Wages	3,926,000	7,916,500	50.4
Paid for contract work	....	48,000	....
Cost of materials	9,714,000	15,857,000	38.7
Value of products	20,529,000	31,470,000	34.8
Value added by manufacture†	10,815,000	15,613,000	30.7

* Percentage omitted where base is less than 100.
† Value of products less cost of materials.

TABLE II—PRODUCTION OF SULPHURIC, NITRIC AND MIXED ACIDS IN 1921 AND 1919

	1921	1919	Per Cent of Total Production, All Industries	Per Cent of Decrease
Total value of products	$20,528,900	$31,470,500	....	34.8
Sulphuric acid (basis 50° Bé.)—				
Tons (3,000 lb.)	1,457,500	1,685,300	50.6	13.5
Value	$15,332,700	$18,113,000	....	15.3
Average value, ton	$10.50	$10.75		
Nitric acid—				
Tons, (2,000 lb.)	2,110	3,150	16.2	33.0
Value	$363,700	$536,700	....	32.2
Average value, ton	$172	$170		
Mixed acid—				
Tons (2,000 lb.)	16,400	28,200	60.7	41.8
Value	$1,316,000	$2,671,500	....	50.7
Average value, ton	$30	$95		
All other products	$3,516,500	$10,149,300	....	65.4

The Chicago Market

CHICAGO, Nov. 9, 1922.

The industrial chemical market continued firm, with a good volume of business reported from most quarters. The tendency on most items is toward higher prices, but buyers are still somewhat reluctant to purchase very far in advance of their immediate requirements. There are no large stocks of any items on hand and buyers are even experiencing some difficulty in locating supplies of certain materials. Freight from the East is quite slow, and this is a factor which makes spot material bring a greater premium than usual over the New York market.

GENERAL CHEMICALS

Caustic soda was unchanged in price, with the market reported firm and supplies moving in a good volume. The ground 76 per cent was available in most quarters at $4.25 per 100 lb. and the solid at $3.50. *Caustic potash* maintained its firm position and a good movement was reported at 7¼c. per lb., basis 88-92 per cent. A good demand for *soda ash* was noted and the price was firm at $2.25 per 100 lb. for moderate lots in cooperage.

Potash alum was rather scarce and spot material was firmly held. The iron-free lump was available in small lots at 5½c. per lb. and the powdered at 6½c. Barium compounds were slightly easier and fair-sized spot stocks were available. *Barium chloride* was offered in one direction at $105 per ton and the *carbonate* from the same source at $90. There was but little demand for the *barium hydrate crystals* and spot material was available at 6½c. per lb. *Sal ammoniac* was in fair demand and the price was firm at 7¾@8c. per lb. for the white granular. *Ammonium carbonate* was quiet and spot material was quoted at 11c. per lb. in single-cask lots. *Bleaching powder* was in fair demand and the price was firm at $2.60 per 100 lb. for drums. *Copper sulphate* was available in fair lots at 6c. per lb. *Carbon tetrachloride* was reported to be in good demand and the price was firm at 9½@10c. per lb. *Carbon bisulphide* was still scarce on spot and what was available was held at 7½c. per lb. Due to the greatly increased price of methanol the price on formaldehyde was sharply increased 15c. per lb. in single-barrel lots. Only moderate supplies were available and a good movement was reported. *Furfural* was quoted at 25c. per lb. in ton lots. *Glycerine* was a trifle unsteady, although refiners maintained the price at 18½c. per lb. for the c.p. material in drums. *Lead acetate* was in fair demand and the white granular was quoted at 12½c. per lb.

Bichromates maintained their firm position and were reported to be moving in a good volume. *Potassium bichromate* was available at 12@13c. per lb. and the *soda* at 9@9½c. *Potash carbonate*, calcined, 96-98 per cent, was quoted at 8¾c. per lb. *Potash cyanide* was very scarce on spot and small quantities only were available at 55@60c. per lb. *Potassium nitrate* was reported to be moving well and the double refined granular was offered at 7¾c. per lb. delivered. *Permanganate of potash* was in fair request and supplies of the imported U.S.P. crystals were offered at 18@19c. per lb.

LINSEED OIL AND TURPENTINE

The market for linseed oil and turpentine was rather quiet the last 2 weeks and buyers were taking on only enough for their immediate requirements. *Turpentine* was slightly lower at the opening of today's market and single-drum lots were quoted at $1.69 per gal. *Linseed oil* was quoted today at 90c. per gal. for the boiled in single-drum lots and 88c. for similar quantities of the raw.

The Iron and Steel Market

PITTSBURGH, Nov. 10, 1922.

The thirty steel companies which make monthly returns of their ingot production show 2,872,415 tons for October, against 2,373,779 tons for September, representing an increase of 21 per cent, each month having had 26 working days. Allowing for the producers not making monthly returns, the rate of production in October was about 40,000,000 tons a year, 9 per cent higher than the rate in June, hitherto the best month of the year. Last month's rate was, indeed, the highest since October, 1920.

A continuance of the October rate for this month and next would bring out a calendar year production of a trifle under 34,000,000 tons, 75 per cent above the production in 1921 and more than 10 per cent above production in either 1912 or 1913, the two greatest tonnage years before the war.

STEEL SHIPMENTS IN EXCESS OF PRODUCTION

During September the steel companies were recovering from the effects of the coal strike more rapidly than was currently assumed, and during October the estimates as to the production rate were below that now shown by the actual returns. In the circumstances the disappearance of delivery premiums on bars, shapes and plates and the decrease in delivery premiums on sheets, the other commodity that had been showing delivery premiums, is readily understood. Much has been said about shortages of cars at steel mills for shipping finished products, but it is known that the small accumulations that developed in September and the first week or so of October have since been reduced, so that shipments in October were in excess of production.

Taking a long range view of the year, one does not see the appearance of there being as heavy steel consumption, in most lines, as was in evidence in 1912 and 1913. The only conspicuous exception is the automobile industry, but its consumption does not represent much more than 5 per cent of the total steel production. It is well to remember, as a collateral indication, that early in the year there was much disposition on the part of steel buyers to anticipate curtailment in steel production by the coal strike, and later it was fully expected that ending of the coal strike would be followed by such railroad congestion as would greatly interfere with the delivery of steel. In the retrospect it is plain that these influences have been of less amount than was expected.

WILL MILLS WITH LEAN ORDER BOOKS MAKE PRICE CONCESSIONS?

Having been under physical restrictions as to operations for many months, the steel mills are now anxious to operate and those that have relatively lean order books will be disposed to seek business by making price concessions. The advances in finished steel products from the low point early in March have been very divergent. Bars, shapes and plates, the cheapest commodities, have advanced about $13 a ton. Tubular goods, a more finished product, have advanced a trifle less than $10 a ton. Nails, at $2.70, are up only $6 a ton, except for there having been sales for a very short time at $2.25. Tin plate, now $4.75, has not advanced at all, except that early in the year the $4.75 price was being shaded rather generally by independents. Sheets, taking the Steel Corporation price of 3.35c. as a basis, are up $7 a ton from last March and $12 a ton from September of last year.

FINISHED STEEL MARKETS QUIET

The finished steel markets are quiet all along the line, and some products are decidedly dull. All mills are well sold for the time being and some are sold far ahead. Buyers are covered, and thus there is no necessity for market activity at the moment. Buying in September was largely by consumers who were not receiving adequate deliveries on their old purchases.

PIG IRON AND COKE

Production of merchant pig iron is now about one-half greater than it was in August. Deliveries are chiefly on old orders, there being very little current buying. Prices are, of course, in process of liquidation, but they decline slowly both because furnaces have old contracts they wish to protect and because, in the absence of important inquiry, energetic price competition is not promoted. Foundry iron has sagged $1 in the week, being now at $29 valley, while bessemer could probably be bought at $32 valley, $1 decline. Basic has shown no development and remains quotable at $29 valley.

Connellsville coke experienced another sudden weakening in the first 2 days of this week, losing 50c. to 75c. in furnace and about $2 in foundry. Furnace coke for spot shipment is $7.25@$7.50 and for shipment next week $7@$7.25, while foundry is $8@$9 according to brand. Production continues to increase. Furnaces now in blast are largely covered to the end of the year.

Industrial

Financial, Construction and Manufacturers' News

Industrial Developments

GLASS—The Wichita Falls Window Glass Co., Wichita Falls, Tex., has resumed operations at its plant after a shut-down for the past 5 months, during which time extensions were made in a number of departments, with considerable repairs to machinery. Employment will be given to about 160 men.

The Pioneer Window Glass Works, Marietta, O., recently acquired by John B. Yates, vice-president of the Premier Glass Co., Pennsboro, W. Va., will resume production early in January. Improvements will be made in plant and equipment.

All glass plants are now in operation at Okmulgee, Okla., with the exception of the Graham Glass Co., specializing in the manufacture of bottles. The active factories include the Southwestern Sheet Glass Co., running at maximum output; the Interstate Window Glass Co., and the Baker Brothers Glass Co.

Plate and bottle glass plants in Belgium are now running full, with sufficient orders on hand to insure continuous production for some months. Crystal plants are operating under considerable curtailed output. Window glass plants are advancing manufacture and 20 furnaces are now producing, the largest number since the close of the war.

PAPER—The Forest Paper Co., Yarmouth, Me., is arranging for the immediate resumption of operations at its local plant, which has been inactive since early in March. Employment will be given to a near-normal working force, with increased wage scale.

The Fort Wayne Corrugated Paper Co., Fort Wayne, Ind., is maintaining full production at its mill at Hartford City, Ind., and has advanced the wage scale 10 per cent.

CERAMIC—The Thomas Maddock's Sons Co., Trenton, N. J., manufacturer of sanitary ware, is maintaining operations at its plant on a reduced working schedule, following a strike of skilled potters, affiliated with the union, due to a refusal to grant the wage increase demand of 20 per cent. Unskilled workers are being added to the force on a basis of 60 cents an hour for a 9-hour day, and guarantee of $40 a week for an 8-hour day in a few months after they become proficient.

A total af about 10,000 operative potters are out at the sanitary ware plants at Trenton, N. J., following the refusal of employers to meet a demand for a wage advance of 20 per cent. A total of 16 potteries in this city is affected.

The Elite Pottery Co. and the Van Pottery Co., Trenton, N. J., have resumed production at their sanitary ware plants, following an agreement with operatives for a 20 per cent wage increase, effective Nov. 1. Other plants that have met the demands of the men are the Ironsides Pottery Co., Bordentown, N. J.; Penn Pottery Co., Philadelphia, Pa.; Potomac Valley Pottery Co., Keyser, W. Va.; Wooster Sanitary Mfg. Co., Fredericksburg, O., and Clarksburg, W. Va.; and the Westcoast Sanitary Mfg. Co., Milbrae, Cal.

IRON AND STEEL—The Gulf States Steel Co., Birmingham, Ala., is maintaining capacity operations at 4 open-hearth mills and all finishing mills, with employment of regular working force.

The Carnegie Steel Co. is arranging for the immediate resumption of operations at its bar mill at Sharon, Pa.

The Pulaski Furnace Co., Pulaski, Va., is preparing to blow in its local blast furnace. The plant will advance production further at an early date.

The Woodward Iron Co., Birmingham, Ala., is now running full at all of its 5 blast furnaces for the first time in a number of years. Four of the stacks are producing foundry pig and the other basic material for Western steel mills.

The American Sheet & Tin Plate Co., Sharon, Pa., is arranging to start up at 10 additional hot mills at its local plant, making a total of 25 out of 30 in service. The working force will be increased by about 700 men.

The wage scale of union puddlers, Youngstown, O., has been increased from $8.93 to $10.12 a ton.

The Bethlehem Steel Co., Bethlehem, Pa., is now operating at about 80 per cent of capacity at its different mills.

All plants of the United States Steel Corp., in the vicinity of Sharon, Pa., are operating at normal production, giving employment to about 6,000 men.

The Crucible Steel Co., Syracuse, N. Y., is maintaining production on a 100 per cent basis. It is said that orders on hand insure continuance for a number of months to come.

METALS—The American Smelting & Refining Co. is making ready for the immediate blowing in of its furnaces at the Monterey, Mexico, plant. Employment will be given to more than 2,000 workers.

The Hercules Mining Co., Burke, Idaho, is planning for an immediate increase in production at its local plant, with important additions in the working force.

The Callahan Zinc-Lead Co., Cœur d'Alene, Idaho, has resumed production at its local plant after a shut down of about 24 months. The working force will be increased gradually until the regular quota of 350 men is obtained.

The Monterey Iron & Steel Co., Monterey, Mexico, is running full in all departments of its local mills.

MISCELLANEOUS—Fiber plants at Newark, Yorklyn, New Castle and Stanton, Del., are advancing production, with an increase of from 5 to 10 per cent in working force. Eight plants at Wilmington, Del., are now giving employment to approximately 2,000 workers.

The H. C. Frick Coke Co., Connellsville, Pa., is developing capacity production at its local plants, and is running higher than at any time since December, 1920.

The Corn Products Refining Co. is arranging to advance production to 85 per cent and higher at its refineries at Edgewater, N. J., Pekin and Argo, Ill., as compared with about 65 per cent of capacity during the past month. Plants are being improved and extended.

The Acme Mfg. Co., Acme, N. C., is arranging for capacity production at its fertilizer-manufacturing plant, following extensive additions and improvements.

All cement mills in the Lehigh Valley district of Pennsylvania are running at full capacity, with practically no reserves on hand. Current orders are absorbing all present production.

The United States Industrial Alcohol Co., Baltimore, Md., is operating at full capacity at all plants. New equipment for the production of high-grade alcohol for motor fuel has recently been placed in service at the Curtis Bay works.

Construction and Operation

Arkansas

EL DORADO—The Lion Oil & Refining Co., Kansas City, Mo., plans for extensions and improvements in its refinery at El Dorado, including the installation of new processing equipment. F. W. Thwing is president, and Victor H. Smith vice-president and general manager.

California

SAN FRANCISCO—The San Francisco Sulphur Co., 624 California St., has completed plans for the construction of a new 1-story sulphur-refining plant, 137x138 ft., on West Grant Ave., to cost approximately $35,000. P. M. Paulson, 624 California St., is architect.

LOS ANGELES—The Buckley Milling Corp., a foreign organization has acquired property at San Pedro Harbor, Los Angeles, as a site for a new metal smelting and refining plant. A rolling mill is also planned, with miscellaneous plant structures. Gordon E. Vance, vice-president, and Edgar T. Carlstorm, consulting engineer, are opening local headquarters for the company, and have commenced preliminary plans. The new plant is estimated to cost in excess of $1,000,000.

SAN FRANCISCO—The Goodrich Rubber Co., 401 Mission St., has completed plans and will soon commence the construction of a new 6-story building, 65x160 ft., estimated to cost about $150,000, including equipment. H. C. Baumann, 251 Kearny St., is architect.

Georgia

SAVANNAH—Preliminary plans are being drawn by the Dunlevi Lumber Co. Inc., for the construction of a new turpentine extraction plant, in connection with extensions in its mills in Liberty and McIntosh counties. The company was recently reorganized, with E. V. Dunlevi as president.

Illinois

EAST ALTON—The Western Cartridge Co. has awarded a contract to the Wimmer Construction Co., Victoria Bldg., St. Louis, Mo., for the construction of its proposed 1-story brass mill addition, 86x240 ft., to cost in excess of $50,000, including equipment. Work will be placed under way at once.

Indiana

HARTFORD CITY—The Fort Wayne Corrugated Paper Co., Murray and Barr Sts., Fort Wayne, has preliminary plans in progress for the construction of a 1- and 2-story addition to its plant at Hartford City. Bids will be called at an early date. Mills, Rhines, Bellman & Nordhoff, 1234 Ohio Bldg., Toledo, O., are architects.

NOBLESVI'LE—The New Process Steel Co. has arranged for immediate operations at the first unit of its new local plant, to be used for the production of steel billets and kindred products. Work is under way on three other plant units, and the structures will be ready for service early in the coming year. Employment will be given to about 200 operatives. J. E. Owen is vice-president, and James Hundley general manager.

EAST CHICAGO—The Jones & Laughlin Steel Co,. Pittsburgh, Pa., has preliminary plans nearing completion for the construction of the initial buildings for its proposed new steel mill on local site, recently acquired. It is estimated to cost in excess of $2,000,000.

EVANSVILLE—A 1-story plant, 45x160 ft., for the manufacture of mirrors and other glass products will be constructed at the works of the Globe-Bosse-World Furniture Co. It is estimated to cost about $25,000. Russ & Karges, Furniture Bldg., are architects.

EDINBURG—The Union Starch & Refining Co., operating a local plant, has acquired the factory of the Temtor Corn & Fruit Products Co. at Granite City, Ill., and will concentrate operations at the latter point. Immediate possession will be taken, and necessary improvements made for a complete refinery, to develop an output more than double that of the Edinburg plant. William G. Irwin is president.

Kansas

PHILLIPSBURG—The City Clerk is taking bids until Nov. 20 for the construction of a new filtration plant at the municipal water works, including the installation of complete equipment. Black & Veatch, Mutual Bldg., Kansas City, Mo., are engineers.

Louisiana

MONROE—The Cosmos Carbon Co., Charleston, W. Va., has acquired the local plant of the Oscar Nelson Co. and will take immediate possession. It is proposed to make extensions and improvements and use the works for the production of carbon black and kindred specialties.

STERLINGTON—The Imperial Oil & Gas Products Corp. has plans in progress for extensions and improvements in its local plant to cost about $150,000, including machinery. A primary feature of the work will include a department for the production of carbon.

Maryland

BALTIMORE—The Locke Insulator Corp., Charles and Cromwell Sts., manufacturer of porcelain insulators, has filed plans for the construction of a new 1-story kiln building, 18x55 ft., to cost about $20,000. Work will be commenced at once.

Massachusetts

MALDEN—Wadsworth, Howland & Co Inc., 139 Federal St., Boston, manufacturer of paint, varnishes, etc., has filed plans for

the construction of a new building at its local plant on Green St., estimated to cost about $95,000.

AMHERST—The State Agricultural College is pushing construction work on its new 3-story chemical laboratory building, 45x111 ft., estimated to cost approximately $300,000, and plans to place the structure in service immediately upon completion. Ritchie, Parsons & Taylor, 15 Ashburton Pl., Boston, are architects.

Michigan

MONROE—The Republic Glass Co. has work under way on the installation of machinery at its new local plant, recently completed, and purposes to place the works in service before the close of the month. It will specialize in the manufacturer of automobile lenses and other kindred glass products. Manuel Llera is president and general manager.

TAYLORVILLE—The Kalamazoo Stationary Co., Kalamazoo, has preliminary plans in progress for enlargements at the former paper mill of the E-Z Bag Co., recently acquired, for a consideration of about $40,000. It is purposed to double the present capacity, providing equipment for the employment of about 500 operatives.

FLAT ROCK—In connection with its proposed local plant for the manufacture of sheet glass products, the Ford Motor Co., Highland Park, will construct a large gas producer plant, for which plans are nearing completion. The entire works will cost approximately $1,500,000. Albert Kahn, 1000 Marquette Bldg., Detroit, is architect.

Minnesota

MINNEAPOLIS—The Lavoris Chemical Co., Western Ave., will break ground at once for the construction of its proposed 3-story plant at 910-22 3rd St., North, for which a general contract recently was awarded. It is expected to have the factory equipped and ready for service early in the spring. It is estimated to cost about $120,000. W. H. Leving is secretary and treasurer.

Nevada

RENO—The local Chamber of Commerce has plans in progress for the construction of a local plant for the manufacture of commercial fertilizer, with initial capacity of approximately 10,000 tons per annum. It is proposed to organize a company to operate the mill.

New Jersey

IRVINGTON—The Clinton Chemical Corp., 1047 Clinton Ave., Irvington, Newark, recently organized, has tentative plans under consideration for the construction of a new plant. The company will operate with a capital of $100,000.

BELLEVILLE—Daniel A. Higgins, manufacturer of dyes, chemical specialties, etc., has acquired the local plant of the Thomson Machine Co., 298 Main St., for a consideration of $28,000. The structure comprises about 19,000 ft. of floor space and will be used by the owner for general manufacture.

New York

LONG ISLAND CITY—The E. Virgil Neal Chemical Works, 11 East 30th St., New York, has acquired the 3-story factory at Borden Ave. and VanDam St., heretofore occupied under lease. Operations will be continued permanently at this location and improvements are contemplated. E. Virgil Neal is president.

LITTLE FALLS—The Barnet Leather Co. is completing an addition to its plant, and plans for the early installation of equipment.

NEW YORK—The Standard Oil Co. of New Jersey, 26 Broadway, has tentative plans under consideration for extensions and improvements in different oil refineries and properties in various parts of the country, to include increased production and storage facilities. An appropriation for the expansion will be made from the recent 400 per cent stock dividend declared by the company.

BROOKLYN—Fire, Oct. 30, destroyed the plant of the Kasebier Chatfield Shellac Co., 126 13th St., with loss reported in excess of $50,000.

Ohio

AKRON—The General Tire & Rubber Co. will soon break ground for the construction of three new additions at its plant, to double approximately the present output of 2,500 tires per day. The structures will be each 1-story, 60x100 ft., 40x180 ft. and 36x100 ft., respectively. William O'Neil is vice-president, in charge.

MARION—The Studebaker-Wulff Rubber Co. has completed plans and will commence the immediate enlargement of its works for considerable increase in output. The new unit, with machinery, is estimated to cost about $50,000.

AKRON—The Miller Rubber Co., manufacturer of automobile tires, has filed plans for the immediate erection of two 1-story additions to its plant on Cole Ave., 70x105 ft. and 40x42 ft., estimated to cost about $30,000. It is expected to have the structures ready for service early in January.

Pennsylvania

MARCUS HOOK—The Union Petroleum Co., Widener Bldg., Philadelphia, has arranged for the immediate construction of a number of additions to its oil-refining plant at Marcus Hook, to cost approximately $500,000, including machinery. A. C. Woodman heads the company.

PHILADELPHIA—The Willden Pottery Co., 711-15 Wharton St., has filed plans for the rebuilding of the portion of its plant, recently destroyed by fire. The work will cost close to $25,000. The company specializes in the manufacture of flower pots and kindred pottery products.

BLANDBURG—The Harbison-Walker Refractories Co., Oliver Bldg., Pittsburgh, has perfected arrangements for additions and improvements in its plants in this vicinity, estimated to cost in excess of $750,000, including equipment.

BOYERTOWN—The Eastern Foundry Co. has commenced the construction of its proposed 1- and 2-story plant addition, 100x150 ft., to be used primarily for cast-iron pipe production. A. S. Keptner, 121 Hanover St., Pottstown, Pa., is architect.

BETULA—The Jaeger Glass Jar Corp. has construction under way for a new plant for the manufacture of heavy glass holloware. It is expected to commence the installation of machinery at an early date.

NEWBERRY—The J. K. Mosser Tanning Co. will make enlargements in its local plant to accommodate a branch of the leather works of the Alexander Brothers Division of the Armour Leather Co., Philadelphia, recently acquired. Equipment will be removed at once from Philadelphia to the local plant. The working force will be increased from 800 to about 950 operatives.

PHILADELPHIA—The M. L. Shoemaker Fertilizer Co., Vernango St., has filed plans for the erection of a new 1-story building at its works to cost about $25,000.

Tennessee

COLUMBIA—The Columbia Oil Co., recently organized by E. E. Williams, McComb, Miss., and associates, has plans under way for the erection of a new local refinery.

MEMPHIS—The Memphis Artesian Water Department is taking bids until Nov. 24 for filtration equipment to be installed at the municipal water works, to include a traveling crane, power apparatus and other operating machinery. Fuller & McClintock, Produce Exchange Bldg., Kansas City, Mo., are engineers.

CHATTANOOGA—The Southern Sheet Steel Co. will take bids at once on equipment for its proposed new local plant for the production of sheet steel and other steel products. It will have a minimum annual output of 55,000 tons and is estimated to cost more than $1,000,000, instead of $400,000, as previously announced. Employment will be given to about 500 men. Bids for the buildings will be asked around the close of the year. W. J. Lynch, vice-president and general manager, is in charge.

MEMPHIS — The Strykre Kot-N-Wood Products Co. is perfecting plans for the early erection of a new plant for the manufacture of composition materials at 1040 Oakland Ave., estimated to cost approximately $65,000.

Texas

TEXAS CITY—The United States Gasoline Corp., has acquired a local site, near the property of the Vacuum Oil Co., totaling about 75 acres of land for the construction of a new four-unit gasoline refining plant, with capacity of 100,000 gal. per day. Work will be commenced at an early date on the initial unit, which is estimated to cost approximately $250,000, including machinery. The erection of the three other units will follow later.

HENRIETTA—The Griswold Oil & Refining Co. is planning for extensions and improvements in the local Beacon refining plant, lately acquired, to include the installation of a new pipe line.

TEXAS CITY—The Swiftsure Petroleum Co. will make extensions in its storage and distributing plant, including the installation of additional tanks with capacity of 110,000 gal. and other equipment.

DALLAS—The Dallas Paper Co., 2211 Law St., is planning for the rebuilding of the portion of its works destroyed by fire, Oct. 22, with loss estimated at close to $60,000.

BURKBURNETT—The Burkburnett Gas Co. is planning for extensions and improvements in its plant, including the installation of additional equipment. Clifford Moore is president.

Virginia

HOPEWELL—The Hopewell China Co. is arranging for immediate extensions in its plant, including the installation of two additional kilns.

RICHMOND—Fire, Oct. 29, destroyed a portion of the plant of the Southern Crockery Co., with loss estimated at about $25,000. It is planned to rebuild. F. F. Socoloff is president.

RICHMOND—The European-American Tobacco Co., Mutual Bldg., recently organized with a capital of $2,000,000, has preliminary plans in progress for the erection of a mechanical drying and redrying plant. A local site will be acquired. C. D. Riggon is president.

West Virginia

BUCKHANNON—The Belgrade Glass Co., manufacturer of flint glass tableware products, is considering the rebuilding of the portion of its plant destroyed by fire, Oct. 29, with loss estimated at $35,000, including equipment.

SHINNSTON—The Alley Glass Co., Bridge St., is reported to be planning for the construction of a new plant to cost approximately $300,000, with machinery. L. E. Alley is president.

New Companies

THE GENERAL ALLOYS CO., Boston, Mass., has been incorporated with a capital of $300,000, to manufacture steel alloys and other metals. Henry H. Harris is president; and Charles Van Stone, 426 First St., South Boston, treasurer. The last noted represents the company.

THE OILLESS PAINT PRODUCTS CO., New York, care of J. J. Finn, Yonkers, N. Y., representative, has been incorporated with a capital of $50,000, to manufacture paint, varnish and kindred products. The incorporators are M. F. Cole, E. Tighe and C. R. Douglas.

THE MID-STATES RUBBER CO., Evansville, Ind., has been incorporated with a capital of $100,000, to manufacture rubber products. The incorporators are John S. Hopkins and George A. Cunningham, both of Evansville.

THE STEVENS PAPER MILLS, INC., Windsor, Conn., has been incorporated with a capital of $200,000, to manufacture paper products. The incorporators are L. T. McManus, C. N. Stevens and George C. Russell, 745 Farmington Ave., Hartford, Conn.

THE NEW CHEMICAL CO., Buffalo, N. Y., care of Gibbons & Pottle, Erie County Bank Bldg., Buffalo, representatives, has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are A. Schneider, M. P. Ryley and B. J. Maier, all of Buffalo.

THE BEACH CHEMICAL CO., St. Louis, Mo., has been incorporated with a capital of $125,000, to manufacture chemical products. The incorporators are J. M. and J. A. Frere, and M. A. Alexander, all of St. Louis.

THE FULTON MFG. CO., 14 North Main St., Canton, Ill., has been incorporated with a capital of 150 shares of stock, no par value, to manufacture chemicals and chemical byproducts. The incorporators are A. Judson and Wilmer A. Allton, and Roy E. Wilhoit.

THE GOVE LEATHER CO., Boston, Mass., has been incorporated with a capital of $10,000, to manufacture leather products. Harold A. Gove, Melrose, Mass., is president and treasurer.

THE NEWTON BELLEEK CO., Trenton, N. J., has been incorporated with a capital of $50,000, to manufacture chinaware and other pottery. The incorporators are Robert Weelans, Arthur B. Harris and William H. Vollmer, 59 Pierce Ave., Trenton. The last noted represents the company.

THE AMBER VARNISH CO., Brooklyn, N. Y., care of W. S. Miller, 837 Manhattan Ave., Brooklyn, representative, has been incorporated with a capital of $20,000, to manu-

facture paints, varnish, etc. The incorporators are L., S. and C. Solomon.

THE KANSAS CITY PLATINUM MINING & SMELTING CO., Kansas City, Mo., care of the United States Corporation Co., 65 Cedar St., New York, N. Y., representative, has been incorporated under Delaware laws with capital of $100,000, to manufacture refined metals. The incorporators are Peter J. Murphy, Byron H. Coon and Joseph R. Lason, all of Kansas City.

THE JACOB W. HOOK CO., 3700 Bank St., Baltimore, Md., has been incorporated with a capital of $50,000, to manufacture tallow, greases and kindred products. The incorporators are C. Howard and H. R. Hook, and E. H. Requardt.

THE VURDEX PRODUCTS CO., Indianapolis, Ind., has been incorporated with a capital of $10,000, to manufacture paints, oils and kindred products. The incorporators are Robert M. Bowes, George G. Rinier and John W. Colley, all of Indianapolis.

THE AUTOCLAVE PORTLAND CEMENT CO., Scranton, Pa., care of the Capitol Trust Co. of Delaware, Dover, Del., representative, has been incorporated with a capital of $100,000, under Delaware laws, to manufacture cement. The incorporators are H. J. Force, Wendel L. Whitehouse and J. H. Schnieder, all of Scranton.

THE GLOBE OIL & SUPPLY CO., Newark, N. J., care of Kanter & Kanter, 747 Broad St., Newark, representatives, has been incorporated with a capital of $50,000, to manufacture oil products. The incorporators are Charles J. and A. G. Ring, and L. Bennes.

THE MIDDLESEX SOAP CO., Boston, Mass., has been incorporated with a capital of $50,000, to manufacture soaps, washing powders, etc. William Perkins is president, and Alfred A. Tutin, 63 Dana St., Cambridge, Mass., treasurer. The last noted represents the company.

THE CHARLES V. WALSH CO., Philadelphia, Pa., care of C. Wilson Roberts, 701-3 Franklin Bldg., 133 South 12th St., Philadelphia, rperesentative, is being organized under state laws to manufacture brick and other burned clay products. The incorporators are Charles V. Walsh, F. E. and W. C. White.

THE EMPIRE PLASTIC & CORK PRODUCTS CO., New York, N. Y., care of J. H. Shetron, 116 Riverside Drive, New York, representative, has been incorporated with a capital of $50,000, to manufacture cork specialties and affiliated products. The incorporators are F. Cutmore and W. E. Smart, Jr.

THE RID-OL CHEMICAL CO., Richmond, Va., has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts. The incorporators are C. M. Langhorne and John K. Hall, both of Richmond, who will act as president and secretary, respectively.

THE KNOX VARNISH CO., Boston, Mass., has been incorporated with a capital of $100,000, to manufacture paints, varnishes, etc. Howard P. Knox is president; and Herbert B. Morse, 140 Oliver St., Newton, Mass., treasurer. The last noted represents the company.

THE FOUR KINGS MFG. CO., care of Franklin L. Mettler, 832 Market St., Wilmington, Del., representative, has been incorporated under Delaware laws with a capital of $25,000 to manufacture soaps, washing powders and kindred products.

THE CAPITOL CITY SPECIALTY CO., Trenton, N. J., has been incorporated with a capital of 2,500 shares of stock, no par value, to manufacture polishes and allied products. The incorporators are John and Michael Corse, and Charles Kulov, 19 Gordon St., Trenton. The last noted represents the company.

THE COPPER FLASH OIL CO., Linton, Ind., has been incorporated with a capital of $100,000, to manufacture petroleum products. The incorporators are Emery A. Powell, Henry A. Maddox and Nathaniel Hagerman, all of Linton.

THE STARKHOUSE CHEMICAL CORP., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., has been incorporated under Delaware laws with capital of $100,000, to manufacture chemicals and chemical byproducts.

THE FORT PITT GLASS CO., Pittsburgh, Pa., care of Raymond B. Gabler, 1608 Commonwealth Bldg., Pittsburgh, has been organized under state laws to manufacture glass products. The incorporators are S. A. Greenlee, H. F. Gabel and K. A. Maratta.

THE QUIMBY TILE CORP., New York, N. Y., care of H. R. Korey, 119 William St., New York, representative, has been incorporated with a capital of $300,000, to manufacture ceramic tile and kindred products. The incorporators are W. Eveleth and W. H. Quimby.

THE MAGNESITE CEMENT PRODUCTS, INC., Boston, Mass., has been incorporated with a capital of $100,000, to manufacture cement and affiliated products. Herbert P. Page is president; and Harold H. Smith, 41 Townsend Rd., Belmont, Mass., treasurer. The last noted represents the company.

THE CREO CHEMICAL CO., San Antonio, Tex., has been incorporated with a capital of $15,000, to manufacture chemicals and chemical byproducts. The incorporators are G. M. Gallaway, William Morgan and Russel Myrick, all of San Antonio.

THE H. G. MILLER CORP., New York, N. Y., care of A. H. Rosenfeld, 80 Maiden Lane, New York, representative, has been incorporated with a capital of $20,000, to manufacture chemical products. The incorporators are H. G. Miller, I. Tilden, Jr., and G. M. Harris.

THE BEACH CHEMICAL CO., Camden, N. J., care of the Corporation Trust Co. of New Jersey, 328 Market St., Camden, representative, has been incorporated with a capital of 1,000 shares of stock, no par value, to manufacture chemicals and chemical byproducts.

THE EASTERN STEEL PRODUCTS CORP., Philadelphia, Pa., care of the Delaware Registration Trust Co., 900 Market St., Wilmington, Del., has been incorporated under Delaware laws with a capital of $500,000, to manufacture steel products. The incorporators are John H. Wilson and Alfred S. Miller, Philadelphia; and H. T. Greenwood, Jr., Merion, Pa.

THE KRO-KO CORP., Smallwood and Eagle Sts., Baltimore, Md., has been incorporated with a capital of $100,000, to manufacture insect powders, chemical specialties, etc. The incorporators are Donald N. Gilpin, Albert C. Hinrichs and William G. Greisemer.

THE MILLIKEN BRICK CO., Wilkinsburg, Pa., has been incorporated with a capital of $100,000, to manufacture brick, tile and other burned clay products. John F. Baldwin, Edgewood, Pa., is treasurer and representative.

THE REMINGTON CHEMICAL CORP., New York, N. Y., has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts. The company is represented by J. H. Ide, 1400 Broadway, New York. The incorporators are F. W. Bein, L. Arnoff and S. Mendelsohn.

THE BAXTER PAPER CO., 409 North Holliday St., Baltimore, Md., has been incorporated with a capital of $25,000, to manufacture and deal in paper products. The incorporators are Wylie M. Baxter, Jr., Stephen S. Mann and Rodney J. Brooks.

THE MIDWEST SUGAR REFINING CO., 326 West Madison St., Chicago, Ill., has been incorporated with a capital of $1,000,000, to construct and operate sugar refining plants. The incorporators are Arthur E. Dike, John W. Davis and Ira H. McKinney.

THE ELKHART ENAMEL & PAINT CORP., Elkhart, Ind., has been incorporated with a capital of $50,000, to manfuacture paint, varnishes, enamels and kindred products. The incorporators are P. C. Kendall, Fred Carpenter and J. W. Mount, all of Elkhart.

Manufacturers' Catalogs

THE CENTRAL STEEL CO., of Massillon, O., has issued a well-printed booklet of 40-odd pages entitled "Agathon Alloy Steels." An introduction recounts the development of alloy steels for high strength, a development which has taken place mostly during the past 15 years. The rest of the booklet contains useful diagrams showing the physical properties (tensile strength, elastic limit, elongation, reduction of area and hardness) of some well-known steels, as these are measured after various approved heat-treatments. Nineteen of these diagrams are given, several S.A.E. specifications being added to the "UMA" steels and a chromium-molybdenum steel, these being special analyses developed by the Central Steel Co. Appended to each diagram is a brief description of the various machine parts for which that analysis is adapted.

THE MEDART CO., St. Louis, Mo., calls attention to Catalog 43, on line shafting equipment. This catalog, which supersedes all previous catalogs and publications, presents facts about the most generally used line shafting equipment, giving dimensions, details of construction and list prices which should enable engineers, designers, mechanics and power users to plan installations of the equipment described. The book comprises 192 pages with illustrations.

PAUL O. ABBE, INC., New York City, announces a new catalog, "H," which deals with the manufacture of paint under its patented process in a pebble mill and also covers its special patented mill for doing this class of work.

THE GRISCOM-RUSSELL CO., New York, in Bulletin 910 treats of multiwhirl and G-R vaneflo coolers, exchangers and condensers for oil refineries.

THE BROWN INSTRUMENT CO., Philadelphia, Pa., calls attention to Catalog 85, on the automatic control of temperatures through Brown indicating and recording instruments.

Capital Increases, etc.

THE GULF OIL CORP., Frick Annex, Pittsburgh, Pa., is disposing of a bond issue of $35,000,000, a portion of the proceeds to be used for expansion, additions to working capital, etc.

THE VITREOUS ENAMELING & STAMPING CO., 1381 Sedgwick Ave., New York, N. Y., has filed notice of decrease in capital from $400,000 to $110,000.

THE SHO-ME PRODUCING & REFINING CO., Sullivan, Ind., manufacturer of petroleum products, has filed notice of increase in capital from $25,000 to $100,000.

THE SCOTT PAPER CO., foot of Market St., Chester, Pa., has arranged for a preferred stock issue of $642,700, a portion of the proceeds to be used for general financing in connection with a new plant addition, now nearing completion.

THE CHICAGO BY-PRODUCT COKE CO., 122 South Michigan Ave., Chicago, Ill., has filed notice of increase in capital from $4,500,000 to $6,000,000.

THE EVANSVILLE ENAMELING CO., Evansville, Ind., has filed notice of increase in capital from $50,000 to $100,000 for general expansion.

THE EMPIRE FLOOR & WALL TILE CO., a Delaware corporation, manufacturer of ceramic tile, has filed notice of organization to operate in New York with an active capital of $1,000,000. The company is represented by E. C. Luther, 137 West 25th St., New York.

THE AMERICAN SMELTING & REFINING CO., 120 Broadway, New York, has disposed of a bond issue of $7,500,000, a portion of the proceeds to be used in connection with property expansion.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its annual meeting in Pittsburgh, Pa., Feb. 12 to 17, 1923.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting April 3 to 7, 1923, at New Haven, Conn.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting May 3, 4 and 5, 1923, at the Commodore Hotel, New York City.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its winter meeting at Richmond, Va., Dec. 7 to 9.

INTERNATIONAL CHAMBER OF COMMERCE will hold its second general meeting in Rome, Italy, March 19-26, 1923.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, East 41st St., New York City: Nov. 17—American Electrochemical Society, regular meeting. Dec. 1—Society of Chemical Industry, regular meeting. Dec. 8—American Chemical Society, regular meeting. Jan 5—American Chemical Society, regular meeting. Jan. 12—Society of Chemical Industry, Perkin Medal. Feb. 9—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting. March 9—American Chemical Society, Nichols Medal. March 23—Society of Chemical Industry, regular meeting. April 20—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting. May 4—American Chemical Society, regular meeting. May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting. May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.

ginning At Home

O MATTER how good a thing is it can be improved! And in the opinion of our resourceful nd G. L. W., whose editorial on "The Roots of the iety" appears in the November number of *The mical Bulletin*, that improvement should begin at ne. His reference is to the local sections of the erican Chemical Society. To many of us the national cies and conduct of that organization have long been arded as fitting subjects for comment and criticism, very often we are inclined to forget the fertile field t lies at our very door. For it is the local section he society that offers the real opportunity for conctive service. It should be built up and strengthl until its influence is recognized in the community. t is not and if the section is loosely organized, ess and ineffective, then the fault is with us and s from within rather than from without that imrement must come.

t traveling about the country we have often reked the difference in character and activity of the groups of chemists. At Pittsburgh, for example, were most favorably impressed by the evidence of closely knit organization, which apparently reis the whole-hearted support of the many chemists hat busy district. On making inquiry, we found this enthusiasm is almost directly traceable to the esting social activities of the section—to the hly smokers and to the annual field day and picnic. t it was at Indianapolis that we discovered the eists as a group playing a leading rôle in local rs. For years it has been the custom of that secto hold weekly luncheons—and contrary to general rience with most weekly luncheons, these are unly well attended. Formerly these meetings were rned almost entirely with subjects of interest only emists, but of late problems of a broader and more al significance have been considered. As a result laymen and the newspapers of Indianapolis have to look to the section for an expression of opinion, lone on matters chemical but on many local issues fessional and public interest.

Its zealous promoters of schemes for obtaining eth from the air" or for solving the nation's motorroblem with Indiana lignite have sometimes sudnl found themselves confronted by a little investiig committee of Indianapolis chemists. Somehow ner these men have a reputation for getting at ottom of things very quickly and usually it is ople of the community who are benefited. Likeot long ago an enterprising department store was viced of the wisdom of abandoning some misleadg dvertising of "radio-active golf balls"—even sales were mounting among enthusiasts who had been led to believe that radio-activity had something to do with longer drives and lower scores.

These are but a few of the ways in which this section of the society is making itself felt in the affairs of Indianapolis. Doubtless similar examples could be found in other parts of the country, but certainly these are sufficient to show that the local section of the American Chemical Society is one of the most logical agencies through which the chemist can be of effective service to his community, to his profession and to himself.

The Science and Art Of Baking

THE art of baking is making its way into chemistry, or perhaps *vice versa*. For years Dr. KOHMAN has been working at Mellon Institute, and in 1919 the American Bakers' Association organized, with the help of the National Research Council, its Research Institute, first at Minneapolis and later at Chicago. In the October number of *The Chemical Bulletin* A. W. LANDSTROM contributes a descriptive article of the Institute's new establishment. The work is divided into two parts: the scientific and technical, and the educational. In the laboratories research is carried on and tests are made for members. Advanced research is also conducted in co-operation with several universities. The laboratories have published findings on control of rope, studies of molds, strength of flour as affected by enzymes in the flour and those added in malt extracts, relation of strength of flour and the viscosity of dough made from it, and a lot of other subjects.

At the same time a school of baking is conducted in which foremen are trained and the incidence of scientific control is made clear to them. In the research laboratory a number of advanced students have already completed work which has led to the degree of Ph.D.

When we consider baking in its chemical and biological aspects, the requirements of temperature and humidity as well as the control of materials having such difficult qualities to master as flour, and the manifest complexities of the phenomena that accompany shortening processes, it soon becomes evident that instead of dealing with a craft to be learned by rule of thumb we are facing a great chemical industry.

Our readers may recall an incident we mentioned last winter when a young graduate chemist asked us if we could help him obtain a position in a chemical works in his home town. The company in question was not seeking additional chemists at the time. So we pointed out a large bakery and suggested that he could surely find plenty to do there. "But they don't want a chemist," he said. "That," we replied, "is what gives you your chance. If they knew they needed one, they would get a man of experience; they wouldn't take you. But if you can get a job of any sort there you can find all

sorts of opportunities to apply chemistry and make yourself a man of great value to them. They need a chemist, but don't know it. You can take almost any job in the bakery and teach them what they need to know—if you have tact. And if you have patience along with tact, they will probably pay you well for your services." Before long these chances will not be available. Bakers are beginning to learn that they are engaged in chemical industry.

Metallurgical Education

ONCE upon a time we were guilty of circulating a "questionnaire"—that was in the days when "drives" and "questionnaires" were more often endured than now. We wished, if possible, to assemble detailed information on metallurgical education, as it then existed, to supplement the impressions gathered by visits to a few of the larger technical schools. Furthermore, it might be possible by that means to discover a course in metallurgical engineering which we could enthusiastically recommend to inquiring high school graduates.

Like most questionnaires, the thing was a failure. One of the schools giving the poorest return on paper looks the best upon inspection, while the opposite also turned out to be true. One thing it did, though, was to collect a large number of curricula. And upon examination they were found to be slight adaptations of conventional courses of study in other branches of engineering.

Apparently it works about like this: A certain institution has a school of mines or is teaching mining engineering. Its attendance drops, or the students who attend ask for more and more information about metal and less about ore. So the dean or somebody in authority says, "We shall offer a degree in Metallurgical Engineering," and the next catalog contains the curriculum. It looks like mining engineering, except that Advanced Metallurgy replaces Economic Geology and a 2-hour lecture course on Non-ferrous Alloys is substituted for Hoisting.

You will say we have used "editorial license"—but the point we wish to make is this: That at the present time American colleges are offering courses which are not metallurgical engineering but are grafts or crude adaptations of older courses such as mining or chemical engineering. (If there are any exceptions we should like to hear about them.) Therefore we find such preposterous subjects as mine surveying, fire assaying, and organic chemistry taking up sadly needed lecture hours and laboratory afternoons. Such are, of course, not "preposterous" in their right place, but are they essential to a metallurgist?

Thoughtful educators and men in industry are coming more and more to agree that the fundamentals of the soundest technical education are a thorough groundwork in the great art of language and the sciences of mathematics, chemistry and physics. Furthermore, to be of greatest value to his country and to himself, the student should also attend a series of studies in history, literature, fine arts, psychology and economics—in fact, if one could find a College of Liberal Arts that would put great emphasis on a thorough understanding of science, that would be the best place for an engineer—any engineer—to prepare for his life work.

But all these things take time. Four years is not enough for these studies, plus the metallurgical specialties, plus mine surveying, fire assaying and organic chemistry. So it is that the 5-year course is bei talked about and experimented with and in some u versities the engineering department has actually b come a branch of the post-graduate school.

Admitting that the more education the better, should still be borne in mind that the large majori of students in American universities will balk at 5- or 6-year course. Even during the fourth year t urge to get out and be doing something is very stron graduation day seems interminably long in comin Of course there are a few who wish to pursue the formal studies further, but the place for the engine to specialize is after he gets his job. If he is prope grounded in science, he can easily learn how to doct a sick blast furnace and will humor its whims wi understanding. The science he can never pick up the works—neither can he be taught the "practic details" on a blackboard. It appears that this ti limitation will never be overcome—at least in met lurgical engineering—until the axe is taken to the pr ent schedules of studies. We look for great things wh some energetic and influential educator goes after o of these hybrids with a big sharp axe, demands th the freshmen be taught how to study, lays out a bro and exacting course in the sciences and humanities, a then puts the onus of co-ordinating these things showing the student what relationship the law of ma action has to open-hearth practice—squarely up to t engineering faculty. Then we shall have a course Metallurgical Engineering.

Wage Rates and National Income

IT IS frequently remarked that the clamor for "t living wage" on the part of certain groups of wo men is improperly based, because it calls for an inco that could not be spent, the goods represented bei more than the whole country produces. It is held th what is really wanted is more goods, and that the w to obtain more goods is to produce more, not to t to pay out more dollars in wages, since by that cou the competition of wage earners would merely incre and market prices of goods would rise.

The reasoning is perfectly sound. It is a case of d tributing the national income. Occasionally it is su gested that if we cannot produce as much as we wa we should import more. There is the 15 billion doll or more that is owing us from abroad, the inter alone on which would amount to a tidy sum and mig be paid in goods, while beyond that we could exp goods such as we can make to better advantage th foreigners and with less labor, and receive in retu goods that require much labor in their production.

This reasoning also seems sound, for the essence foreign trade is that of exporting goods that one make easily and getting in return goods that one h difficulty in making.

In the combination of these two ideas, however, th is a feature that does not seem to have been brou out. That feature is that the three groups of la that are making the most trouble from an econo standpoint, those that appear to want more than th natural share of this country's production by comp son with other classes of workers, are engaged in tivities that cannot be supplemented by importatio No one at all conversant with current conditions have any difficulty in identifying these three grou Everyone knows that they are the coal miners, artisans in the building trades and the railroad wo

s. They are all being paid too highly by comparison ith what the remaining workers in the country receive. It is altogether impossible for us to import coal in antity. Our coal is the most easily mined of any and e should export rather than import. We cannot im- rt garages and dwelling houses, which are being built great numbers this year and at an altogether un- asonable cost. We cannot import transportation.

In the case of manufactured goods we depend upon ports to prevent production costs from going to reasonable levels. We pretend, in theory at least, construct our tariffs to cover the proper and legiti- te differences in cost of production as between the ited States and foreign countries. If the theory re carried out in practice, then any demand for un- asonable wages on the part of workmen or unreason- le profits on the part of manufacturers would induce ports and thus bring to bear a restrictive influence. coal, transportation and building, this principle can- t apply.

Our new tariff has been rather generally criticised d unpleasant economic consequences from it have n predicted. As a wage raiser the tariff cannot be dited for the highest relative wages that are being d in the United States, for they are being paid in es of activity the tariff does not touch. Nor, on other hand, can the tariff be blamed for the eco- nically unsound condition of wages being unduly h in the three lines of activity to which reference been made.

William Bragg And His Crystal Units

DESPATCHES purporting to be special and by cable, lately appearing in various newspapers, tell of the covery of the crystal unit by Sir WILLIAM H. BRAGG l his son, Prof. W. T. BRAGG. Expository information ich follows the announcement has been misleading, l, so far as we have observed, characteristic of wspaper chemistry."

he despatches have their origin in the September eting of the British Association for the Advancement cience held at Hull in September. Here Sir WILLIAM vered an address from which the information was en. In a previous work by these eminent physicists the X-Ray Analysis of Crystals they tell of the gin of their investigations, which followed the work Dr. LAUE of the University of Zurich. Dr. LAUE was bitious to cause and measure the differentiation of Xays, on the hypothesis that they partake of the na- e of light. By means of a spectrometer with a dif- tion grating, the length of so-called light waves etermined. The grating, as is well known, consists n arrangement of equidistant parallel lines, ruled in at numbers on glass or a metal surface. The spac- n must be of the order of the wave lengths measured; s sodium light with a wave length of 0.0000589 can liffracted through 24 degrees by a grating of 7,000 s to the centimeter—that is, a spacing of about 0143 centimeter.

ow the X-ray wave, if there is such a thing, is t 10,000 times as short as the waves of sodium light, to construct an appropriate grating for this pur- is unthinkable. The spacing would be of the order f istances between the molecules of a solid. This very appealed to Dr. LAUE, because in crystals we have lid in which the atoms or molecules must be ar- ged in some definite order. By experiment he demonstrated that, if a pencil of X-rays is made to traverse a crystal, the diffracted pencils show arrangements about a primary beam in regular patterns, and these patterns differ according to the crystals employed. This gave Mr. LAUE his results. In other words, X-rays were diffracted through crystals, as light rays are produced from diffraction gratings.

Then the BRAGGS, father and son, at that time attached to the University of Leeds, became actively interested in Dr. LAUE'S conclusions and in the photographs which he published, because they concluded that this very diffraction of X-rays would give them the basis for the more intimate study of atoms and molecules in crystals. Magnificent work on their part, by HULL, ST. JOHN, BAIN, KAYE and other workers in England and America, has resulted in the invention of the X-ray spectrometer, its application to mixtures of very fine crystals, and the solution of many baffling problems of allotropy, isomerism and solids of colloidal size. Many readers will recollect the contributions to theoretical metallurgy, published by Dr. BAIN at intervals in these columns. Others, more familiar with the work done on the other side on salt crystals, will remember, for instance, that in the crystals of such halides as sodium chloride, potassium chloride, etc., it was concluded that each atom of one element organizes itself between four associated atoms of the other, so that, instead of aggregations of molecules forming the crystals, we have a symmetrical order of opposed atoms which constitute the crystal as a whole.

Now it is evident that the BRAGGS have gone beyond this, and reached a new conclusion in regard to crystal units. We quote from Sir WILLIAM'S address at the Hull meeting of the British Association in September:

"Every crystal is built up of units, and every unit is the counterpart of the crystal. The crystal unit contains every kind of atom or bond; every feature and every property that the crystal possesses as a whole.

"X-ray analysis tells us the number of atoms in the unit, and is throwing more and more light on their arrangement.

"The limitation to our knowledge of the properties of gases and liquids is severe. We remove it when by aid of X-ray analysis we examine the nature of crystal units, because the unit displays all the properties of the solid.

"A crystal has elasticities, thermal expansions, thermal and electrical conductivities, dielectric capacities, optical activities, and these not only as scalars, but as vectors.

"The many properties, for example, of quartz as a crystal, are all displayed by its crystal unit—i.e., by three molecules of SiO_2 arranged in a particular way. They are not characteristic of the separate molecules of SiO_2, still less of the separate atoms of Si and O.

"When we know the exact arrangement of the nine atoms of this unit, we can apply all that we know about quartz to that small group. In this way a wide field of research opens out in which the crystal unit plays a part like that of the molecule in other fields. And the magnitude of the results may be just as great."

It is difficult to grasp the bigness of this work, or to measure its significance. It is almost like a flash of lightning over an undiscovered country, and we await with eagerness the more detailed publication of studies by this gifted father and son on the order and arrangement, and the nature of the organization of atoms and molecules in solids.

Readers' Views and Comments

Why We Are Publishing the Articles on European Conditions

To the Editor of Chemical & Metallurgical Engineering

SIR:—The publication of my first two articles on "European Conditions as I Saw Them" and my letter on "Who Financed the German Economic War" have raised the question of my purpose in expounding a situation that may be regarded by some as being more in the domain of politics. It is true that there is a political aspect in the subject under discussion, but of far greater importance is the fact that in Germany's present plight we have a condition that has such a concrete repercussion on the economic status of the whole world that it is worthy of the attention of engineers. Far be it from me to tackle the subject from its political side. My aim is to bring home to American technical and industrial men the fact that they, more than all the politicians and bankers together, ought to know the real causes of existing industrial conditions in Germany, in the expectation that by this means engineers could be moved to develop a policy that would bring back all of the European industrial countries to a stage of constructive production.

In a conversation on March 13, 1922, with Prof. Edgard Milhaud of the International Labor Office at Geneva, Switzerland, he pointed out that a very great part of the blame for the distress in Europe is traced directly to America, which, he said, financed the war so efficiently but is now taking refuge under a turtle shell when so much assistance is needed to finance peace. Subsequently I learned things that brought me to the conclusion that Germany was really leading an economic war as outlined in my first article; that politicians were lulling their nationals with notes and counter-notes spread broadcast; that bankers were watching hawk-like for opportunities to do business and that unscrupulous middlemen were beating all the others in making sure of the bird in hand rather than laying plans to get two in the bush. Finally, I think now as I did April 24 when I wrote in my diary as follows:

"America, although now the greatest loser from the above unhealthy condition, because her industry and commerce feel acutely the effect, is bound to come out the winner in the end, not only because she has the raw materials and modern machinery, but mainly because her industrials, merchants and workingmen possess, as a rule, the mentality of square dealing to an extent not existing in the above-mentioned countries [France, Belgium and Germany]. But instead of waiting until this turn arrives *per se*, which in itself might also lead to the equally bad, if not worse, condition of only America working while the others were bankrupt, we must do something to stop such disastrous consequences and try to pave the way to a sane return of normal conditions when everyone will have an opportunity to do his share of honest work. And we must hasten the arrival of such conditions by using the least radical means."

The fact is that now, only a little more than 6 months after the above was written, America more than any other industrial country is working and enjoying relative prosperity. But we are gradually approaching the undesirable condition of becoming a mere receptacle of the world's wealth, with little, if any, international interchange, while the stricken European countries are beginning to pour their wrath on the "tentacular United States" (Les Etats Unis Tentaculaires), a very suggestive heading on an article in the *Echo des Mines et de la Métallurgie*. We in the United States know that we are not as guilty as all that, but we do nothing to dispel the rapidly growing misconception of the European technical press.

No, when I wrote the series of articles now being published in *Chem. & Met.*, I did not intend to take politics nor did I aim to play the omniscient accuser. My real aim was to inform the American technical world through the columns of a technical paper what I, as an engineer and one of your staff, saw and learned while traveling through Europe. In so doing I was guided by the sincere expectation that I might open up a hitherto unexpressed line of thought in order that engineers, American engineers included, might initiate a policy that would hasten the arrival by the least radical means of a condition where everybody could have an opportunity to do his share of the world's work. I am confident that the reaction of American as well as foreign engineers and industrials, after they have read the full series of articles, will be in this direction.

New York City. J. S. NEGRU

What Is Steel?

To the Editor of Chemical & Metallurgical Engineering

SIR:—Only a day or so after reading your editorial on "What Is Steel?" (issue of Nov. 8), I clipped the following from the Brooklyn *Daily Eagle:*

Memory Test
Can You Answer These?

1. Who discovered that the blood circulates through the body?
2. Why does the wind whistle?
3. What is steel?
4. When is Indian summer?
5. Where is the Cape of Good Hope?

"Ha! ha!" said I to myself, when I got to No. 3, "there's where I fool the Memory Test." Nevertheless I bought the *Eagle* the next day (possibly to find out Why does the wind whistle?) and read:

"3. Steel is a compound of iron containing 0.25 to 3 per cent of carbon."

There you are! And it took you nearly a page to say it. MARTIN SEYT

Titanium Alloys

Of the titanium alloys, only four are in commercial use, ferrocarbon titanium, ferrotitanium, cuprotitanium and manganotitanium. Information regarding these alloys is contained in Serial 2406, "Titanium," which may be obtained by addressing the Bureau of Mines, Washington, D. C.

European Conditions as I Saw Them*

Impressions Gathered During the Extensive Trip Through the Devastated Coal Districts of Northern France—Proof of Wanton Destruction and Active Reconstruction Are Conspicuous, as Illustrated by the Typical Cases at the Anzin and Béthune Coal Mines

By J. S. Negru

ON MY TRIP from Brussels to Paris I passed over many of the battlefields of the late war, and observed that a large number of the small cities nd towns were still in ruins. The removal of débris nd the reconstruction of homes and factories were nly partly done, being necessarily postponed until at east a part of the needed money could be obtained from eparation funds. The fields, on the contrary, were lready well leveled, and looked as if they had never een covered with numberless shell craters of varying izes. Later, I learned that agriculture, more than ny of the other devastated French industries, was lready practically on a pre-war basis. In the industries other than coal mining, the condition was quite he same, and progress in their reconstruction could e measured only by the amount of money available or actual work.

In the coal industry, however, the conditions are ntirely different. Here it is not sufficient merely to ave the money for reconstruction work, for not only ere surface plants at the mines totally or partly detroyed, but the underground workings were also damged. Anyone who is familiar with the geology of the oal seams of northern France and the complicated nderground workings necessary for mining operations an readily understand why, in addition to large sums f money, a vast amount of arduous work is necessary repair a damaged French coal mine.

Visit to the French Devastated Region

In May I had an opportunity to visit the devastated oal region, including the mines of Anzin, Lens, Béune, Liévin, Noeux and Bruay. All of the physical cts and data regarding these mines have been pubshed in elaborate monographs on the French devasted industries, and consequently I shall not indulge a repetition of this phase of the subject. On the her hand, I should like to mention the relation of the rench coal mines to the bitter animosity existing tween Germany and France.

I visited the coal region after I had been in Germany nd had talked there with intellectuals and common eople. Consequently I thought it well, when I was the ground in France, either to corroborate or refute e German contention that the destruction of the mines as not done wantonly, but that it was an inevitable sult of warfare. I wanted, also, to discover how uch truth there was in the German statement that the construction of the destroyed French coal mines was luntarily held back by the French mining companies.

I know now that both of these contentions are wrong. here was wanton destruction of the coal mines, and fere is, on the part of the French people, a feverish sire to restore the mines to working condition as fast funds can be obtained.

It may suffice to cite in corroboration of these statements two typical cases based on official information obtained during my visit.

Destruction of the Anzin Company Mines

The Anzin company was working twenty shafts in 1913, and produced on an average 11,400 tons of coal per day. On Oct. 8, 1918, all of the mines were in good order on the surface as well as under ground. Ventilation and pumping were going on as usual, and the mine horses were still under ground.[13] On this date the general director of the company received an order from the German military authorities to remove the horses from the mines and to stop ventilating and pumping operations. A few days later the technical staff of the Anzin organization was assembled and carried away to Liége, Belgium, and systematic destruction of the mines was begun.[14] All of the tipples, boilers, hoisting machinery, compressors, ventilators, electrical equipment and power houses were completely destroyed. One washery was totally destroyed and another badly damaged. Three of the briquet plants were totally destroyed. The Thiers shaft was badly damaged, 135 miners' houses completely razed, 15 railway switch and signal stations completely destroyed and about 13 miles of track systematically dislocated. Apparently, there was not time to complete the work of destruction, and so the repair shops, some of the screens, washeries, briquetting plants and coke works escaped. A few days before the armistice, the bombarding of this district added to the destruction, so that at the signing of the armistice all of this important coal district was a heap of ruins, with shafts damaged and the mines flooded.

Reconstruction of the Anzin Company Mines

Immediately after the armistice reconstruction work was begun. At the end of June, 1919, six of the twenty shafts were already in such shape that they could be partly worked, yielding a daily output of 1,270 tons, as compared with about 11,400 tons in 1913. The comparative daily production in these six mines for corresponding periods in 1913, and June, 1919, is shown in the following figures:

1913: 679, 873, 412, 453, 808, 1,268
1919: 87, 612, 120, 80, 295, 76

By the end of 1921 the total daily production of Anzin company was about 7,100 tons, as compared with 11,400 in 1913, and at the present time the daily production has approached the 8,000 ton mark. Only two of the twenty mines cannot be worked yet and some of the repaired mines produce now even more than before the war, as can be seen by the following figures of average daily production in tons of coal, in 1913 and in December, 1921:

Mine	1913	Dec., 1921
Lagrange	873	975
Bleuse Borne	415	442
Ed. Agache	539	708

*This is the fifth of a series of articles by Mr. Negru on this subject. The preceding articles appeared in the issues of Oct. 18, Oct. 25, Nov. 8 and Nov. 15.

[13]Haulage in the coal galleries is done by horses. Once they are in the mines, they are kept there as long as they are alive. This is the invariable rule.

[14]Note the date. On Oct. 8, 1918, revolution was already fomenting in Germany.

These figures show clearly that the company has been working feverishly to repair the destroyed mines and to bring the coal production as fast as possible to the pre-war figure.

Destruction of the Béthune Company Mines

The case of the Béthune company furnishes a more striking example of wanton destruction. Shafts 8 and 8bis were occupied by the Germans on Oct. 11, 1914, and were abandoned by them only in the beginning of October, 1918. As these shafts were only a few hundred yards from the first-line trenches, it is small wonder that the surface works were reduced to a heap of ruins. But it was not to be expected that the shafts would be found in such condition as to give unmistakable evidence of wanton destruction. Official evidence indicates that this was done after September, 1917. When it was possible to inspect these shafts, it was found that the metal linings had been badly damaged, especially at the 50- and 100-ft. levels of shaft 8bis. The accompanying drawing of this shaft in elevation shows better than words can describe the condition of its metal lining.

It is now officially known that, in order to accomplish this result, the Germans drilled a series of holes about 10 in. in diameter and about 100 ft. deep at a distance of 3 ft. from the lining of the shaft. These holes were charged with high explosives at the 50- and 100-ft. levels, and similar charges were placed in the shaft at corresponding positions. The firing of these charges quickly accomplished the work of destruction. In addition to this, the shafts themselves had the appearance of craters, due to the explosion of well-placed charges. At one shaft the crater measured about 70 ft. in diameter, and at the other 50 ft., while the ground was well shattered to a depth of about 50 ft.

Difficulty of Reconstruction Work

The ground in this district is highly water-bearing, and consequently the repair of the shafts has been a gigantic and difficult task. Nevertheless the company has already succeeded in repairing the shafts up to within a few feet of the bottom of the craters. The repair work still to be done will require several years, although the work of destruction took but a short time. How thoroughly and systematically the latter was done can be judged by the time required for the vast amount of reconstruction work already completed, as well as by the work remaining to be done.

These two examples suffice, I think, to show that wanton destruction on a large scale was perpetrated by order of the German military authorities. At whose instigation this work was done, we can judge only by circumstantial evidence. It appears to have been accomplished in the interest of German industrials. But of the actual facts of destruction, the German people are not generally aware, even at this date.[15]

Need of Acquainting the German People With the Conditions in the Devastated Districts

During this visit to the French coal fields I talked with many leading French engineers, and was led to

ELEVATION SHOWING THE DESTROYED METAL LINING OF SHAFT 8BIS, BETHUNE, FRANCE

suggest the merit of having a commission of German engineers visit the devastated coal region. I felt that an honest report by such a commission would aid the German people in getting a fair conception of the wanton destruction of the mines and of the reconstruction work already accomplished, and thus alleviate in some degree the bitter spirit of hatred displayed toward the French. Particularly, I broached the subject to Messrs. Champy, the general director of the Anzin company, and Gruner, vice-president of the Central Committee of French Collieries. They all saw the value and utility of such a plan, and the general response was that such a commission would be welcome. When I returned to Germany after having visited the French coal fields, I discussed the subject with many people, and particularly

[15] At this point permit me to recall a personal incident that occurred a few days after the armistice was signed. I was then in St. Ghislain, about 5 miles from Mons. In visiting a tile plant, which had been transformed into a bath house during the German occupation, I observed the utter destruction of all the machinery. In the repair shop my attention was attracted particularly to an ordinary blacksmith's bellows which was still covered with leather and apparently in good condition. In view of the fact that the Germans were greatly in need of leather during the war, I wondered why they had not taken this. Thereupon Mr. van H., the owner, showed me that it had been sharply cut from top to bottom, thus rendering it useless.

vith Prof. Dr. Matschoss, director of the Verein deutscher Ingenieure (Society of German Engineers), and vith Prof. Dr. Rassow, general secretary of the Verein leutscher Chemiker (Society of German Chemists), and expressed the belief that if the findings of such a commission were made public through the technical press, t would do the German people a world of good. Here, nowever, the suggestion met with passive indifference.

Policy of Miners' Dwelling Rentals

In the reconstructed coal mining towns in France, I understand that there will be practically no private dwellings. The companies are erecting the buildings, and will rent them to their employees at the nominal sum of 10 francs (about 85 cents) per month. This is for a two-story brick house. It will be interesting to see what effect this policy has on the relations between employer and employee. At first sight it may appear to have the advantage of always keeping the miners contented through their low rental, but on the other hand t leaves open the question of whether they may be paying indirectly, through lower wages or otherwise, and ultimately giving the companies a fair return for the money invested in housing. I should expect this policy to work better in Germany, where the workmen have long been accustomed to obedience and paternalism. The French, on the contrary, as I know them, may not prove so docile; and I have wondered what the French miners may think and do when they find themselves in the permanent position of tenants on company-owned property.[16]

War Damage Compensations

I had not been long in Europe before I got the impression that reparation payments in France, particularly the sums awarded as compensation for war damage, are quite often in excess of the value of the actual loss. That this was well founded is proved by the fact that recently the French press has been active in denouncing this harmful practice. In the latter part of July, 1922, I read of a typical case where an industrial had put in a large claim for relatively small damage and his claim was accepted. This case is now being dealt with by the French judicial authorities. Shortly after this I noted in the London *Financial Times* for July 31, 1922, the following item under the caption "Huge Expenditures":

"It is computed that the French Government has spent between 80 and 90 billion francs in reparations which are considered as 'a financial advance to Germany,' but it would be interesting to know what percentage of the amount could have been economized by more practical control over the spending department. An enormous amount has been squandered unnecessarily, not to speak of the amount which, up to a year ago, went into the pockets of dishonest architects and other intermediaries to whom the war-devastated districts have been as a 'land flowing with milk and honey.'"

I may add that in the course of conversation with responsible authorities I have learned that the French Government is actually engaged in correcting these erstwhile abuses.

Other articles on this subject by Mr. Negru will appear in subsequent issues.

[16] In X, a German company-owned town, the barber told me with pride that he is the only independent tenant as far as employment is concerned. The social welfare work for German employees has contributed greatly to developing what is, in reality, a bonded working population.

Cracking Processes for Petroleum

The growing demand for greater gasoline production in order to satisfy the increasing demand for motor fuel has given rise to numerous tried and experimental cracking processes for increasing the yield of gasoline from crude oil. The National Petroleum Association in its Bulletin 134 has recently published the following compilation of the best-known processes which are being used successfully in the refineries of the mid-continent field, classified by inventor, owner and method:

Burton—Standard Oil Co., Indiana; pressure.
Hoover—Hoover Co., Chicago; catalytic.
Cross—Gasoline Products Co., New York; pressure.
Dubbs—Universal Products Co., Chicago; pressure.
Coast—Cosden & Co.; pressure.
Cherry—C. & C. Development Co., Kansas City.
Jenkins—Jenkins Petroleum Process Co.; pressure.
Fleming—Richard Fleming Co., New York.
Ramage—Barnsdall Corporation, New York.
Rittman—United States Government; pressure.
Greenstreet—Pressure.
Ellis—Standard Oil Co. of New Jersey.
Isom—Sinclair Refining Co.; pressure.
Alexander—
Adams—Texas Co.; pressure.
Holmes—Texas Co.; pressure.
Parker—American Gasoline Corporation; pressure.
Blaisdell—Mutual Oil Co.; pressure.
Von Tilberg—Pressure.
Ormonde—Pressure.

The chief refineries of the country using cracking processes successfully are as follows:

Cosden & Co., Tulsa, Okla.—*Coast.*
Barnsdall Refining Co., Barnsdall, Okla.—*Ramage.*
Globe Oil & Refining Co., Blackwell, Okla.—*Cross.*
White Eagle Oil & Refining Co., Augusta, Kan.—*Burton.*
Sterling Oil & Refining Co., Wichita, Kan.—*Fleming.*
American Gasoline Corporation, Kansas City, Mo.—*Jenkins* and *Parker.*
Lakeside Petroleum Co., Augusta, Kan.—*Jenkins.*
Roxana Petroleum Co., Wood River, Ill.—*Dubbs* and *Cross.*
Texas Co., Port Arthur, Tex.—*Holmes.*
Midwest Refining Co., Casper, Wyo.—*Burton.*
Standard Oil Co., Neodesha, Kan.—*Burton.*
Standard Oil Co., Whiting, Ind.—*Burton.*
Sinclair Refining Co., E. Chicago, Ind., and Whiting, Ind.—*Isom.*
Indian Refining Co., Lawrenceville, Ill.—*Cross.*
Atlantic Refining Co., Philadelphia, Pa.—*Burton.*
Pure Oil Co., Heath, Ohio—*Cross.*
Petroleum Refining Co., Latonia, Ky.—*Cross.*
C. & C. Developing Co., Kansas City, Mo.—*Cherry.*
Mutual Oil Co., Chanute, Kan.—*Blaisdell.*
Gulf Refining Co., Port Arthur, Tex.—*Alexander.*
Humble Oil & Refining Co., Houston, Tex.—*Burton.*
Aetna Refining Co., Louisville, Ky.—*Ormonde.*

Nickel Steel for Locomotive Connecting Rods

Connecting rods of 3 per cent nickel steel are installed on about 1,400 locomotives on the North-Western Railway of England. Most of these engines are equipped with Joy's valve gear, which is driven by a link working off the connecting rod. Bending of the rod at this link connection has been frequent—about fifty replacements per year being recorded from this cause. Two recent breakages of such nickel steel connecting rods, occurring while the engines were operating at high speeds, are exciting much comment in the British engineering periodicals. One was doubtless due to a large flaw in the rod; it is suspected that the other was caused by a local heating of the rod in a railroad smithy. This is strictly against regulations, which forbid local shops from doing any work whatever on nickel steel rods. It appears as another instance of the extreme care which must be exercised to prevent abuse of alloy steel, pending the time when mechanics are sufficiently educated to handle it intelligently.

Standardization Of Enameled Apparatus For Chemical Purposes*

By Emerson P. Poste
Director of Laboratories, Elyria Enameled Products Co.

Standardization as Regards Types of Enamels to Withstand Varying Degrees of Corrosive Action—Materials of Construction, Uses, Methods of Temperature Control

ALTHOUGH the manufacture of enameled equipment for the chemical industries is a relatively new development in this country, it has advanced to a stage that warrants consideration from the point of view of standardization. Further experience in its construction and use will secure the well-merited place which it has already gained among the available types of apparatus for the carrying on of the more exacting chemical operations.

Standard Enamels

The enamels which are used in the chemical and allied industries differ in certain respects from those used for ordinary household ware. A piece which is to serve as a domestic culinary utensil or a sanitary fixture need not have a high chemical resistance, but should possess a particularly pleasing appearance by way of color, gloss and opacity. The raw materials which promote these qualities often do so at the expense of chemical resistance. Heavy metal oxides are commonly used. But for chemical work proper resistance without the use of heavy metals is the prime requisite. A pleasing appearance is desirable, but is of secondary importance.

Corrosive Action Classified According to Relative Severity

Commercial experience has caused the manufacturer of enameled apparatus to offer to the trade a series of enamels with chemical properties suited to the several demands of the industry. From a chemical standpoint these enamels may be considered in four classes, thus divided by the demands made for them.

Neutral or Very Slightly Corrosive Materials

The mildest set of conditions which enameled ware may be called upon to meet involves the handling of materials which are not markedly corrosive but do become discolored or contaminated by contact with the ordinary metals of construction. This grouping includes neutral solutions in general, those slightly acid on hydrolysis, a great variety of organic compounds and a group of materials such as chlorine gas which, in the presence of traces of moisture, react with metals. Enamels of this type have given satisfactory service in connection with the following typical substances: oil during deodorization, alcoholic extracts, aniline hydrochloride, ammonium nitrate during evaporation and fusion, bleach liquor, chlorine gas, dry hydrogen chloride gas, hydrogen peroxide, tincture of iodine, phenol, salicylic acid, acetic anhydride, dry sulphur dioxide, tannic acid, bromine.

Weak Acids

In the second classification conditions demand an enamel with a sufficient chemical resistance to serve under more definitely acid conditions with particular reference to the organic acids as a whole, and traces of free mineral acids. The group also includes solutions definitely acid on hydrolysis. As a general case a metal container would be actively attacked, resulting not only in the contamination of the product being handled but in the gradual destruction of the apparatus. Typical cases of satisfactory service in this class are the following: ammonium sulphate, inversion of sugar, citric and tartaric acids, acetic acid, acid brines, moist chlorine, tin chloride with traces of free hydrochloric acid, zinc chloride, mixed acids relatively low in water content.

Resistance to Strong Acids

The third classification involves resistance to all mineral acids with the exception of hydrofluoric. Contact with a metal container would cause a very rapid destruction thereof. Conditions of more severe acid nature not named in connection with the former classes naturally fall here. Typical cases include hot hydrochloric acid, nitric acid, dilute mixed acids.

Resistance to Alkalis

The fourth point as to chemical resistance of enamels is that of the relation to alkalis. As a general statement it may be said that acid resistance of enamels is promoted by the use of materials which are subject to action by alkali. Experience has shown that ammonia has no appreciable effect on enamels. The hydroxides of the alkaline earths are somewhat active. The free hydroxides of sodium and potassium are quite active, excepting at very low concentrations and in the absence of water. Caustic soda solutions under 5 per cent in strength have been successfully stored in enamel-lined units. The carbonates of sodium and potassium can be safely handled over quite a range of concentrations. Sulphides of these bases are quite active. In general enamels are not particularly resistant to alkali.

Factors Influencing Choice of Enamel

The foregoing consideration has been general. It is difficult to reduce the situation to definite standards. Matters of temperature, type of unit, limitation of size, complication of design and manner of use must be considered in a given case. The more severe the chemical conditions and the more resistant the required enamel the more difficult is the production of a satisfactory unit. Demands of increasing chemical severity, therefore, must be met by smaller units, simpler designs and more careful operation. A condition that may be safe at atmospheric temperature will be far more difficult at higher temperatures. Conditions that are mild at 50 lb. steam pressure may be chemically out of the question at a pressure of 200 lb. A solution successfully handled by one type of enamel in an open unit may give off vapors more active than the liquid itself, necessitating the use of a more resistant enamel in a closed unit. Each case must, therefore, be treated by itself. A statement of the essential chemical conditions by the pro-

*Paper presented at the Eighth National Exposition of Chemical Industries, Ceramic Day, Sept. 15, 1922.

Fig. 8—Tilting reaction kettle with agitator.

spective user and a careful analysis of the situation by the manufacturer are required if the proper grade of enamel is to be furnished on apparatus of correct design.

One may logically ask why the most resistant enamel is not used on all types of ware. As a general rule the processing temperature of enamel of a given class increases with an increase of chemical resistance. This in turn greatly multiplies the manufacturing difficulties and limits the maximum size and flexibility of design. To use an enamel of more than the required resistance puts an unnecessary burden on the manufacturer and in turn a higher price on the product.

Standard Constructions

As a whole there are two standard types of construction used in the manufacture of enameled apparatus. The one involves the application of a relatively thin coat of enamel to steel, the other a thicker coat of an enamel of a different type to cast iron. Each has its advantages. The steel construction makes possible larger units, but certain manufacturing features limit the larger sizes to mild conditions of use. With smaller pieces more resistant enamels can be used and more severe service met. But the cost per unit volume increases with decreasing size and other features contribute to the relative undesirability of very small units of steel construction for chemical work. On the other hand, there are various points which make the manufacture of smaller cast-iron units very feasible. As a class cast-iron enamels process at lower temperatures than steel enamels of the same resistance. Other details go to make this type of construction desirable on certain lines of work. Some manufacturers furnish steel equipment only, others cast iron only, and still others follow both lines.

Standard Uses

The classification of enameled apparatus from the point of view of the chemical operation to be carried on therein is difficult because chemical manufacturing processes deal with such a variety of substances and treatments. It is more logical to consider the standardization of enameled units from the point of view of the mechanical operations being performed therein.

In classifying enameled apparatus in accordance with the mechanical use, five headings may be considered: mixing, storage, transportation, evaporation, and reaction. These standard operations will be considered with reference to the grades of chemical conditions previously outlined.

Mixing

The mixing problem may range from the rapid dissolving of a solid in a liquid to the formation of a difficult emulsion. The batch may be a few gallons or as large as 7,000 gal. Chemically it may only be required to keep from contact with steel a product which would be discolored thereby; or possibly acids are present which would rapidly eat through the unit at the minutest metallic contact. For mild service large mixers with complicated agitators of wood or special metals are possible. Conditions of intermediate severity call for smaller units and the use of an agitating device coated with enamel, contact with even small areas of the relatively resistant alloys often not being permissible. Such agitators must be of simple design and operated from the top of the unit. With the most corrosive compounds still smaller units of very simple design must be supplied to assure a satisfactory piece of machinery. The mixing unit may be a single-shell tank or it may have a jacket or other device for temperature regulation. It may be of an open or closed top construction.

Typical mixing problems that are successfully met with the proper design of enameled equipment are the following: Mixing of face creams and tooth pastes, preparation of cod liver oil emulsions, mixing of phosphate sirups containing free acid.

Storage

Enamel-lined storage tanks are subject to the same general controlling factors as mixing units. They may be horizontal or vertical as desired. A large variety of accessories are possible for tanks for mild conditions, while severe acids must be met with simpler constructions.

Among typical materials stored are the following: Edible oils, sirups, elixirs, perfumes, extracts, tincture of iodine, phenol, alcohol, c.p. mineral acids.

Transportation

The transportation on a large scale is at present confined to conditions of a mild nature. Liquors containing free organic acids are being transported in enamel-lined tanks on railroad cars. The carrying of smaller batches of liquid from one part of a plant to another is an accomplished fact for all classes of chemical conditions. Open or closed top tanks mounted on trucks or castors find a ready application.

Typical cases of this type include the conveying of chlorinated organic compounds containing free chlorine, the distribution of alcohol to various departments, and the carrying of small amounts of mineral acids about the plant.

Evaporation

In presenting the use of enameled units for the evaporation of liquids it is well to have clearly in mind the fact that the evaporation to dryness of large quantities of material, or the rapid concentration of large volumes of solution, cannot be successfully accomplished in this type of apparatus. These problems fall to the drum drier and other relatively complicated devices. The enameled unit has for its field the handling of smaller quantities of the more sensitive or corrosive products.

The simple evaporation problems are accomplished in open units. Evaporation in closed units is usually of the vacuum type. The destructive acids are generally confined to the pan. A variety of accessories may be used on larger evaporators for mild service, but the unit for severe acids must be far more simple.

Distillation, a special case of evaporation, may be carried on at atmospheric or reduced pressures. The pan is essentially the same as the closed evaporator. The condenser and receiver are enameled excepting where severe acid conditions or substances sensitive to metallic contact are confined to the pan. Copper condensers are sometimes permissible.

Another evaporating unit which is finding a growing application in the chemical trade is the enameled tray for the evaporation of liquids or the drying of moist solids. These are used in both atmospheric and vacuum evaporation.

The installations of various forms of enameled evaporators are numerous. A few typical examples will suffice: The evaporation and crystallization of c.p. salts

such as thorium nitrate, sodium iodide and copper chloride, the vacuum concentration of fruit juices, concentration and fusion of zinc chloride, preparation of hydrosulphite stripping compounds, concentration of aluminum chloride, evaporation of acid rare-earth bromide solutions.

Reaction Units

As reaction units are classified those pieces of apparatus in which specific chemical reactions such as nitration or neutralization are carried on. They may be of a great variety of types as conditions demand—open or closed, plain or jacketed, large or small. Typical installations involve the chlorination of organic compounds, reduction by metals and acid, preparation of silver nitrate from metal and nitric acid, salting out of dyes, generation of hydrocyanic acid, manufacture of ethyl chloride, processing of acid sodium phosphate, manufacture of so-called "phenol condensation" products.

Standard Temperature Control

Problems of temperature control may involve heating, cooling, or holding at a given temperature.

Heating by Steam

The heating of the contents of an enameled unit is accomplished in various ways. Steam under pressure may be passed directly into the material or it may be applied externally by means of a jacket around the tank or by coils within the tank.

If a jacket is used the permissible pressure is a matter of particular importance from an enamel point of view. Steel has an elasticity by virtue of which it can safely "breathe" due to pressure changes. But the less elastic enamel cannot follow such a movement of the steel without rupture. (This point should not be confused with the relative thermal expansion of enamel and steel, to be considered later.) A safe working pressure for an enameled unit may be taken as about one-half of that which would be reasonable for the same structure unenameled. In the case of jacketed vacuum units proper correction for vacuum must be made.

If the permissible jacket pressure under a given case does not furnish the desired temperature, superheating may be resorted to.

Under chemical conditions which will permit the use of metal steam coils within the batch, more rapid evaporation or higher temperatures can be thus realized by using high-pressure steam. Such coils are commonly furnished in plain copper, nickel-plated, tinned or silver-plated copper, or aluminum.

Oil Heating

Certain types of reactions demanding high temperatures but relatively low heat absorption are often made possible by the use of oil as a heating medium. Oil heated in a separate heater may be circulated through the jacket or through metal coils within the batch. Oil in the jacket may be heated by direct fire applied to the bottom of the jacket or by high-pressure steam in coils within the jacket. Specific conditions, chemical and mechanical, will govern the procedure in a given case.

Molten Alloy Bath

Some reactions demand higher temperatures than can be obtained by steam jackets, a more rapid flow of heat than would result from the use of oil as a heating medium and involve chemical conditions such that metal coils are out of the question. Such situations have been successfully met by the use of a bath of molten alloy, heated by a fire beneath.

Direct Fire

A final possibility for the production of high temperatures is the use of direct fire. As a general rule this method is undesirable. Enamels of the proper composition have a thermal expansion so related to that of the metal beneath that the two materials can pass through a reasonable temperature change without the setting up of strains causing rupture of the enamel. But if the temperature change is severe and local, trouble may result. No conditions existing with permissible steam pressures or oil-heating temperatures should cause distress. But with direct fire the heating is likely to be locally excessive, causing severe strains on sudden changes of temperature. Under conditions of evenly applied heat, accomplished by proper checkerwork or baffles, very satisfactory service can be realized. Small units heated over a flame of low intensity applied to a large portion of the dish are found to be very practical. If the material being treated has a relatively low thermal capacity—for instance, an oil as compared with an aqueous solution—conditions of excessive strain from direct fire heating are less likely to be produced.

Cooling and Insulating

The problem of the cooling of a liquid is not frequently encountered. In a few cases cold water or brine have been circulated through jackets or coils. Condensers are usually equipped for the circulation of water or brine.

It is often desired to prevent the rapid exchange of heat between a unit and the atmosphere. Air confined in a jacket or the use of the common insulating materials are frequently resorted to.

Rate of Heat Transfer

A statement as to the rate of heat transfer through enameled metal is pertinent. The partition through which heat is called upon to pass may range from a thin coat of enamel on $\frac{1}{8}$-in. steel to a relatively thick coat on 1-in. cast iron. Hence the rate of heat transmission varies between quite wide limits. As a maximum it is approximately one-half, and as a minimum about one-fifth that of copper. These values are on the assumption that the same conditions as to temperature difference, velocity and other factors exist. The comparison also refers to copper of the thickness used in the construction of apparatus for similar operations.

Conclusion

Thus it is seen that by the combination of various standard elements of design, enamel, method of temperature control and accessories, equipment can be constructed to serve a great variety of purposes. While a given piece of apparatus may differ from any previously made, it usually embodies only standard features assembled to meet a particular case. The would-be purchaser does well, therefore, in recognition of these facts, to submit his case clearly and fully so that the manufacturer may intelligently make such a combination of standard elements as may best suit the uses to which the apparatus is to be put.

Manufacture Of Alloy Steel for Airplane Shafts*

Experiments on the Manufacture of Nickel-Chromium Steel in the Basic Heroult Furnace—To Produce Airplane Shafting With No Trace of Transverse Structure, It Is Necessary to Use Very Good Raw Material and Refine With Two Oxidizing Slags as Well as the Usual Carbide Slag

By Dr. E. Kothny

INCREASING demands upon steel of quality, used in motor car and airship construction, require continual improvement in the metal. Its properties depend primarily upon the care used in its manufacture. Subsequent treatment during fabrication may spoil a good steel, but can never correct errors occurring prior to the ingot.

Furnace Investigations

It is by no means easy to investigate the influence of a particular step in the furnace operation. In our present state of knowledge this is best done in an empirical manner—by taking a series of heats, worked as nearly alike as possible except for one factor, which may be varied within reasonable limits. In the studies reported herewith, ingots made in this way were worked up into finished pieces in the regular manufacturing routine, and a study of the qualities of these finished pieces gave useful information on the effect of the variable under consideration.

Our regular melting practice on nickel-chromium steel was as follows: A heat is melted in a 2½-ton basic Heroult furnace from a cold charge of selected plain and alloy scrap in such a way that when molten the P, Mn and C are removed by an oxidizing slag. After these elements are low, the slag is removed, the bath recarburized with petroleum coke and a white slag prepared to deoxidize and remove sulphur. After the proper white slag is obtained, FeMn and FeSi are added to complete the deoxidation, whereupon FeCr is added. The furnace is tapped after holding it for a period of time depending upon the temperature of the heat.

Influence of Time of Solidification

One such heat was first used to determine the joint influence of deoxidation and time of solidification. To make sure that the heat was overoxidized, two oxide slags were made up, each of which contained an excess of ore. After the second had been skimmed and the white slag melted, only enough FeMn and FeSi were added to remove red shortness. One-half of the heat (Part A) was tapped immediately, so the influence of the deoxidizers was a minimum in this part. A second test taken of the metal remaining in the furnace (Part B) showed slight red shortness, so a little more FeMn was added, the current switched on for 30 minutes, and the furnace then drained.

We then had two ladles of metal, "A" poorly deoxidized and "B" well deoxidized. Analyses were identical (C 0.40, Mn 0.42, Si 0.22, P 0.03, S 0.015, Cr 0.48 and Ni 2.54) except Part B had 0.50 per cent Mn. Each ladle poured three ingots: (1) in a preheated sand mold, (2) a cast-iron mold at 400 deg. C. and (3) a cast--iron mold at 50 deg. C. Both ladles were poured at a low temperature—a skull was left in each. All ingots were big end up, tapering from 25 to 23 cm. on a side, 1.1 m. long. Each had a sinkhead, and charcoal was placed on the ingot to prevent rapid freezing at the top. All ingots settled during freezing and were dense except A2 (poorly deoxidized metal in a hot iron mold), which rose slightly and showed blow-holes at the upper edges.

By probing with 4-mm rods the time of solidification was noted, as follows:

A1.....35 min.	B1.....35 min.
A2.....15 min.	B2.....15 min.
A3.....13 min.	B3.....13 min.

Preheating the iron mold has no real difference, since A3 and B3 were cast last and coldest and should be expected to freeze somewhat quicker. Sand-cast ingots A1 and B1 solidified suddenly once freezing started, but those made in iron molds solidified gradually from the edge to the center and from the bottom upward.

Tests on the Ingots

All the ingots were nicked and broken in the lower third. A1 and B1 had the same fracture: coarse crystalline over the whole area, with no difference edge to center. A2 and B2 were also alike: coarse granular in the center, but columnar at the rim. A3 and B3 both revealed thin, leafy or laminated crystals throughout, reminding one of low-carbon ferrochromium. Thus the ingot structure as revealed by fracture was independent of the state of deoxidation.

A slice cut immediately back of the fracture was smoothed and pickled 24 hours in 1:1 HCl (arsenic free). Again the deoxidation practice failed to make a difference. A1 and B1 (cast in sand molds) showed a slightly porous texture, due to the sudden solidification, except about the rim, which was dense for a depth of 1.5 cm. All ingots cast in iron molds were dense throughout.

Tests on Heat-Treated Bars

Nickel-chromium steel of this analysis is ordinarily used only after working and heat-treatment. Its acceptance is based upon proper tensile and impact values and a fibrous fracture, both longitudinally and at right angles to the direction of working. Therefore the lower third of each ingot was reduced 79 per cent to a billet 11 cm. square, it having previously been found that a 65 per cent reduction was sufficient to develop the best physical properties. Temperatures (by optical pyrometer) were 1,050 deg. C. at beginning of rolling and 1,000 at end. All pieces rolled well.

Test specimens were cut from each of these small billets after they had been annealed 10 hours at 700 deg. C. (Forged pieces of Ni-Cr steel are usually an-

TABLE II—FRACTURES OF ANNEALED BARS

Ingot	Broken Across the Grain	Broken With the Grain
A1	Center granular; fibrous at rim; loose structure; flows poorly.	Pronounced transverse splintering faintly granular; small ability to flow.
B1	Fracture fibrous and loose; flows well.	Pronounced transverse splintering; fibrous fracture throughout; small ability to flow.
A2	Fracture about two-thirds granular; flows well.	Transverse splintering; partly granular; flows well.
B2	Fibrous fracture; flows very well.	Transverse splintering; fibrous fracture; flows well.
A3	Fracture partly fibrous; flows well.	Faint transverse splintering; partly granular; flows well.
B3	Fibrous fracture; flows very well.	Faint transverse splintering; fibrous fracture; flows well.

nealed for machinability and to relieve internal stresses before final heat-treating, and test-pieces should be put through the same program.) Two pieces 5 cm. square and 25 cm. long were taken in a longitudinal direction, and two slices 3 cm. thick across the section. Longitudinal test specimens were turned to 10 mm. diameter and the transverse specimens 8 mm., with length between gage marks equaling $11.3\sqrt{\text{Area}}$. Longitudinal impact specimens were 2 cm. square, notched 5 mm. deep ending in a round hole 4 mm. in diameter. In the testing machine the anvil was set so the specimen was broken as a beam with 120 mm. clear span. Corresponding dimensions of the transverse impact specimens were: 1 cm. square, notched 2 mm. with angular groove at 45 deg., and broken on a 7-cm. span.

All test-pieces were water-quenched from 820 deg. C.; the longitudinal pieces drawn at 600 deg. C. for 15 minutes and the transverse at 500. Results are given in Table I.

Fractures were determined by taking the annealed 5-cm. bar ends, and 3-cm. slices (from which the test specimens were machined), notching them 5 mm. deep, and breaking under a steam hammer. Results are given in Table II.

Although steel such as this is rarely used in the annealed state, it was thought that physical tests would give some light on the subject. Therefore test-pieces were cut from the annealed 11-cm. billet, giving values shown in Table III.

Discussion of Results

Comparing A1 with B1, A2 with B2 and A3 with B3 in Table III shows that there is no great difference in the mechanical properties and fractures of poorly and well-deoxidized steel billets in the annealed state. There is also no difference in the longitudinal samples of steels slowly and quickly cooled (compare A1 and A3, etc., Table III); however, transverse test-pieces of the slowly solidified steel show a pronounced transverse splintering and an undesirable loose structure. To bear out these conclusions, annealed billets were smoothed and pickled. A2, B2, A3 and B3 showed a perfectly dense structure. Slowly cooled ingots A1 and B1 showed a slightly porous structure in the center and a dense structure at the rim, 15 mm. deep; despite reduction of nearly 80 per cent, the cavities in the ingot had not been closed.

As to the heat-treated specimens, Tables I and II show that the quality of the quickly solidified and well-deoxidized steel B2 and B3 is most excellent. Although the poorly deoxidized steel would pass ordinary tensile and impact requirements, the granular fractures appearing in whole or in part would be cause for great suspicion. These tests seem to show that poor deoxidation practice induces partly granular fractures in heat-treated bars, but fails to show observable differences in the fracture or macrostructure of the ingot or of the annealed bars, or in the tensile and impact properties of the latter.

Speed of solidification affects the quality to a far greater extent. It causes differences in all the tests recorded. Especially in the rolled bars, the slower the steel solidifies the more pronounced is the transverse structure or splintering (*cf.* B3 and B1, Table I). In order to avoid this last-named defect, it has become

our practice to pour alloy steels at as low a temperature as possible.

Steel for Airplane Shafting

Austrian army specifications for airplane motor shafting call for the following mechanical properties, when made on pieces of dimensions given above:

	Longitudinal Test Lb. per Sq.In.	Transverse Test Lb. per Sq.In.
Elastic limit, maximum	156,500	156,500
minimum	135,000	135,000
Ultimate strength maximum	170,700	170,700
minimum	149,500	149,500
Difference between the two above (maximum)	14,200	14,200
Elongation, minimum	7 per cent	4 per cent
Contraction, minimum	45 per cent	15 per cent
Notch toughness	8 kg.-m.	2.5 kg.-m.

All fractures, and the nick and bend test, shall show a full fibrous structure, and a good ability to flow.

When called upon to make this material in large quantity, we first selected some blooms from our stock analyzing C 0.20 per cent, Mn 0.4 to 0.6, Si 0.2 to 0.3, Cr 1 to 1.5 and Ni 4 to 4.5 and made up some shafts therefrom. All tests were passed with ease, the transverse tests showing 170,500 lb. ultimate, 6 per cent elongation, 36 per cent contraction, and impact value of 6 kg.-m. Broken tensile test-pieces and the nick and bend test could scarcely distinguish between longitudinal and transverse fractures. Thereupon a number of electric furnace heats of that analysis were made, but unfortunately the steel did not give a good fibrous fracture, although the other mechanical tests were easily met.

These defective heats were made in what was thought to be substantially the same manner as the practice which produced the metal in stock (outlined in the early part of this article). As far as known, the kind of metal charged was the only difference—the older, successful metal was made of Styrian plate scrap, while the defective heats were made of electric steel scrap from our own plant. The latter was very low in phosphorus, in contrast with the plate scrap, consequently only one oxide slag was necessary to keep this element down. Judging from the experiments given in the early part of this article, two oxide slags—such as are necessary for impure Styrian scrap—would result in a harmful overoxidation of the bath. Our efforts to produce acceptable metal therefore led us first to investigate the influence of the charge upon final quality.

Influence of the Charge

A fairly large quantity of uniform scrap of highest quality was available, being, in fact, electric steel of our own manufacture. Five identical charges were made up, each consisting of Ni-Cr steels having 4 to 4.5 per cent nickel. Five other charges were made up of carbon tool steel—to these the required nickel was added directly after melting. In this way we determined that it apparently made no difference whether the nickel was residual in the melt or was added separately.

A sample taken immediately upon melting showed that all ten heats were very hard, therefore ore was added sparingly. As soon as the heats were sufficiently soft—the last samples were red short—they were deoxidized with FeMn. This addition was made before slagging off so that the deoxidation stage might be as long as possible. Immediately after slagging off FeSi was added to the bare bath and a white slag made up. After 30 minutes a sample would always show red shortness and FeMn and FeSi were added until red shortness disappeared. Thereupon FeCr was added. Ten minutes later the current was switched off.

Deoxidation with FeMn before slagging off caused unduly high manganese in the final analysis, since more FeMn had to be added after the white slag had been prepared. Five of the heats were therefore made by the old method—i.e., FeMn and FeSi added after the white slag had acted for 30 minutes.

All heats were slightly overheated; they were held in the furnace 4 minutes before pouring. Our optical pyrometer was less satisfactory than the "spoon" test[1]—the temperature of the bath in these heats was such that 15 to 25 seconds passed before the metal would crust over.

An ingot 16.4 cm. (6¼ in.) round from each heat was rolled to 6-cm. square rods. Two slices 25 mm. thick were cut, nicked 5 mm. in the center and hardened in water from 840 deg. C. One was broken in that condition by a single blow from a steam hammer. The other was broken after tempering at 400 to 450 deg. C. (depending upon its hardness) in a lead bath. Ultimate strength was estimated from the size of the Brinell impression.

All these ten heats had a fibrous fracture in the hardened state, but a very objectional granular fracture and poor ability to flow in the tempered condition. Repeating the heat-treatment did not change these results.

We were therefore reluctantly faced to the conclusion that the purest raw material (either with nickel or without it) does not always produce a steel with good transverse properties. Evidently the process of melting or working the heat influenced the quality—since, as it has been indicated, we were assured that we were able to make acceptable steel unknowingly.

Influence of Casting Practice

In order to extend the conclusions reached in former experiments—detailed in the first part of the paper—to high-alloy steel for aircraft, two heats were made of purest electric scrap and poured into 8-in. molds of various sorts and temperatures. It is unnecessary to recount these in detail, since they confirmed our expectation—viz., that long cooling in a sand mold is associated with pronounced transverse structure, and that if iron molds were used, it appeared immaterial whether they were chilled or warm, top or bottom cast. Therefore we held to our standard practice: cool pouring the steel in blood-warm molds.

Tests Taken While Working the Heat

In the hope that the circumstances which determine the structure might be recognized when testing a heat during the working, we took a series of large samples from two heats, immediately after certain additions had been made and also some time later. These samples were poured into 3-in. square molds and forged to a slab 2x10 cm. cross-section under a small steam hammer. Two pieces 5 cm. long were cut from these slabs, notched 5 mm. deep in a longitudinal direction (i.e.,

[1] The spoon used for taking the furnace tests is washed in slag and about 2 kg. melted steel dipped up, and skimmed. A stop watch determines the time required to form a skin on the surface of the steel. Comparative figures result only if all additions have been made. If FeMn alone is in the bath, gases boil up and agitate the surface, so the time recorded is unduly long. If FeCr has also been added, the time is too short, where FeSi increases the time to crust over.

TABLE IV—TESTS DURING WORKING TWO HEATS

arallel to the long dimension of the slab). One was ardened and broken, the other drawn back to the hardess required for airplane shafts, and then broken.

Rather poor sheet scrap was charged for these heats: oth were worked with two oxidizing slags. After the econd one was skimmed, and the white slag obtained, nough FeMn was added to free the steel from red nortness. The first large sample was taken at this me. Sequence of further additions and samples are oted in Table IV. (It may be noted that in Heat No. the FeCr was added in two parts.) Ferrosilicon was dded to the ladle, and the fourth sample taken when puring the ingots.

Table IV shows that the finished steel of both heats ould conform to specification. Intermediate samples ow that the steel has a fibrous fracture as long as contains no chromium; the structure became granular both the hardened and drawn condition upon adding eCr and in fact the more granular the higher the romium.

Time for Adding FeSi

Ferrosilicon, in turn, improves the structure. Could show a still better improvement when exerting its fluence for a longer period?

To determine this point, another heat was made om the same kind of material, but only one oxidizing g was used. Ferrosilicon and FeCr were added simulneously to a bath which was relatively cool. A spoon t taken after the second sample (Table V) showed 2 seconds. This increased to 35 seconds just before oping; consequently the heat was held 10 minutes.

As can be noted from Table V, this heat did not f the requirements. The only differences in working re the use of one oxide slag and the time of adding FSi. We concluded that one or the other of these is sponsible for transverse structure. Since overoxidizaon is universally regarded as damaging, we rejected is as an influential factor and turned our attention to e proper way to make the FeSi addition. Other hts were made of the same sheet scrap, and the FeSi ded at various times or in the ladle. Results were uformly bad. As a last resort we then turned to the ning practice.

Thereupon we made two 6-ton open-hearth heats of st-class steel, one containing 5 per cent Ni and the er free of alloy except 0.8 per cent C—otherwise their composition was almost identical. The ingots from these heats were divided into six piles and remelted in the electric furnace. Three of the melts were made with one oxidizing slag, the other three with two; otherwise the practice was identical.[2]

Of the heats made with one oxidizing slag, two developed transverse structure and granular fracture in the rolled, heat-treated rods; the third was fibrous with only a trace of transverse weakness—it alone passed specifications. All three of the heats made with two oxidizing slags passed specifications easily, all having fibrous fractures, flowing well, and in only one was there a faint suggestion of transverse weakness.

These experiments seemed to prove beyond doubt that working a heat of alloy steel with two oxidizing slags, far from being detrimental, actually improves the quality. However, it is not able to produce steel of perfection from quite inferior material, as we very quickly demonstrated when using impure junk. Due regard must be paid to the quality of the charge.

Successful Furnace Practice

In order to avoid rejections in finished airplane shafts, the following practice was adhered to:

Selected scrap of best quality is charged, melted and worked with two oxide slags. (Use ore rather than mill scale.) After skimming the latter, the finishing slag is made up, using 1 kg. FeMn per ton of steel to hasten the reactions and bring the latter white in a minimum of time. When it is white, enough FeMn is added to eliminate red shortness, whereupon FeCr and FeSi are added. When the additions are melted, the heat is well stirred, a 3-in. ingot poured in a chill, and a spoon test for temperature should not take more than 30 seconds to film over. This indicates that the metal should be held in the furnace 5 minutes.

The test ingot is forged to a slab 2x5 cm. in cross-section. Two pieces 2 cm. long are cut off and nicked longitudinally. Both pieces are hardened in water from 800 to 850 deg. C., and one drawn back in a lead pot at 400 to 450 deg. C. If the tempered piece shows a fibrous structure and a good ability to flow, the heat is cast into forging ingots for making airplane shafts

[2]Steel melted with two oxidizing slags requires an excess of 3 or 4 kg. FeMn per ton to eliminate red shortness. It was found later that the finished steel (which must contain 1 per cent chromium in order to give it the necessary hardening properties) cannot hold more than 0.8 per cent Mn, to avoid granular fractures

If the fracture of the quenched piece only is fibrous, the steel is cast into ingots for rolling. An even better test was introduced later. A piece of the same test ingot is forged to 2 cm. square, notched 5 mm. deep, and heat-treated to 165,000 lb. per sq.in. strength. When broken, the fracture must show no trace of granular structure.

A small test ingot, 6½ in. round, is cast with the remainder of the heat. This is rolled to a 6-cm. square rod. Two slices 2.5 cm. thick are cut from this bar, nicked 5 mm. across the face, and heat-treated to an ultimate strength of 165,000 lb. per sq.in. (as determined from the Brinell test). After breaking under a single steam-hammer blow, the fracture must be fibrous and show good ability to flow. This latter test is somewhat more severe than the furnace test, and will reject occasional heats which might give trouble when making airplane shafting.

No differences in microstructure can be observed in the heats which have granular fracture and those which are fully fibrous.

Legal Notes

Contract to "Manufacture" May Not Be Termed "Work and Labor" So as to Evade Tax

The Circuit Court of Appeals of the United States has decided that the manufacture of munition parts under a contract and from materials furnished is subject to the munition manufacturer's tax, this finding affirming a decision of the District Court in an action brought by the Dayton Brass Castings Co. against the Collector of Internal Revenue. A certiorari has been denied the Brass Works by the United States Supreme Court, which affirms the lower courts, 277 Federal, 227.

It appears from the facts that the Canadian Car & Foundry Co. had a contract for the sale of shrapnel shells to or for the use of the Russian Government, and had sublet to a machine company at Dayton, Ohio, a contract for making the fuses for the shells. The machine company in turn contracted with the Dayton Brass Castings Co., by which it was to furnish the latter brass ingots which were to be put through the Dayton company's foundry, molding the same into small castings, which were to be united by the machine company with other parts to complete a fuse. For this service the castings company was to receive a specified price per pound.

By the provisions of title 3 of the act of Sept. 8, 1916 (39 Stat., 780) and known as the "munition manufacturer's tax," a tax was imposed upon every person manufacturing "any part of" fuses, the tax to be 12½ per cent of the entire net profits actually received or accrued during the year from the sale or disposition of such articles manufactured within the United States. This tax was imposed upon the castings company, which paid the tax under protest and brought this suit to recover.

Two propositions were considered. One was that, since plaintiff had to do with only one part of the fuse, it was not a manufacturer within the meaning of the act. But the established rule is that one who makes a part which is intended to be and does by the act of another become merged into the kind of munition specified in the act is a manufacturer subject to tax.

Then the plaintiff contended that it did not receive profits "from the sale or disposition of such articles," but was in effect paid only for work and labor expended on the property of another. The court says, taking together the sections of the statute above noted, it concludes that the tax was imposed upon the business of manufacturing, and was measured by the profit received upon the sale or disposition. If there were no profits, the tax would be nothing. That the castings company received profits from its contract was not disputed. While the company did not make "sales" it did make a "disposition" of the articles. Having received the metal and having cast it into form, the company disposed of the castings and so far disposed of the subject matter of the contract as to turn these articles over to the machine company and get payment for its service. This court held to be a disposition.

A very substantial contention against this holding was that under the doctrine of *ejusdem generis* the statutory phrase "sale or disposition" can include only dispositions of the character of a sale. But the court says this rule may not prevail to the exclusion of the other rule which requires every word and phrase be given force and meaning, if possible. And if plaintiff's contention were right, the statute could be evaded wholly or in very large part by similar contracts as this one, and a court will not sanction such evasion of the law by dividing the manufacturing process into several steps by separate persons.

Antimony Industry of Hunan, China

Hunan has been producing antimony for over [illegible] years. Discoveries were made as early as 1897, and since that time new ones have been made yearly, according to reports from Consular Clerk Gordon Burke, published in *Commerce Reports* for Oct. 9, 192[illegible] The demand during the war greatly exceeded the supply, causing the price to soar to ten times its normal level. Hunan became a large exporting center for antimony and many mines and smelters sprang up all over the province. The termination of the war resulted in a cessation of the abnormal demand and the price went down to a very low level. The selling price in many cases is still much below the actual cost of production, which has caused about nine out of every ten mines to stop operations. It is believed, however, that the lowest level in the industry has been reached, and that a slight improvement is now to be noticed. By this is meant that the richest mines and the ones that can the least to operate are now being exploited to their full worth. During 1921 there were 921 mines in operation.

Deposits of antimony are abundantly and widely distributed throughout Hunan. The districts around Paoching, Anhwa and Sinhwa are particularly rich in the supply of this mineral. Hsikuangshan, a hill located in the Sinhwa district, is called Antimony Hill because of the richness of the deposits found there. The antimony ore of Hunan is of a very high grade and is free from arsenic and other impurities. The antimony content of the ore runs from 20 to 65 per cent. Regulus exported by the Wah Chang Mining & Smelting Co. is 99.95 per cent pure. The Herrenschmidt process is generally used in extracting antimony regulus. Since the demand for regulus has fallen off, antimony ore is manufactured into trioxide, commonly called antimony oxide.

Distillation and Concentration Of Dilute Nitric Acid

An Experimental Study of the Concentration of Nitric Acid—The Distillation of Water-Nitric Acid Mixtures and of Nitric Acid-Sulphuric Acid Mixtures—Graphic Study of the Results

By E. Berl and O. Samtleben
Translated by F. C. Zeisberg*

Translator's Note: In *Chemical & Metallurgical Engineering*, vol. 25, pp. 1103-6 and 1145-50 (1921) appeared a translation of an article by P. Pascal in *Annales de Chimie* covering a very complete investigation of the distillation of HNO_3 solutions and H_2SO_4-HNO_3-H_2O mixtures. Apparently about the same time Pascal was making his experiments there was under way in Germany an independent investigation of the same problem, the results of which have recently appeared in the *Zeitschrift für angewandte Chemie*. Since the results obtained by the two investigators differed considerably and since the readers of *Chemical & Metallurgical Engineering* had already been made familiar with the earlier results, it seemed desirable to afford them the opportunity to familiarize themselves with the later work also. The following translation has hence been prepared, only such portions of the original article being used as bear directly on the work of Pascal.

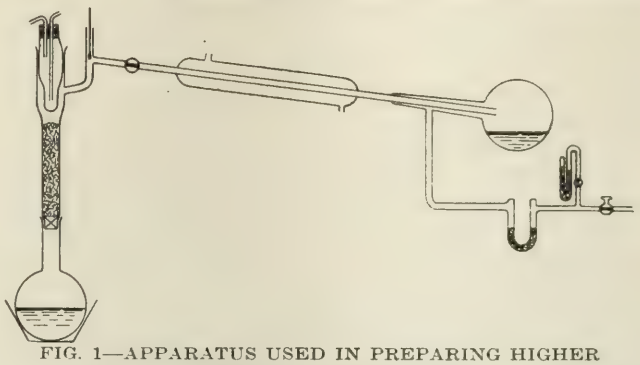

FIG. 1—APPARATUS USED IN PREPARING HIGHER STRENGTH NITRIC ACID

FORMERLY nitric acid was manufactured by decomposing Chilean saltpeter with concentrated sulphuric acid. This process was widely developed hnically; from the standpoint of distillation in stages Uebel[1] and the Badische Anilin und Soda Fabrik[2], and m that of operation in a vacuum by Valentiner and hwartz[3]. The acid obtained by these processes was hly concentrated enough to meet the needs of the lustry, and even the weak acid simultaneously obined in comparatively small amounts was utilized, or, ere no use could be found, was returned to the retort h the saltpeter and redistilled. The question of hly concentrating weak nitric acid became most portant as the problems of obtaining nitric acid from oxidation of ammonia and atmospheric nitrogen re solved. Since in the arc process a 35 per cent d and in ammonia oxidation at best a 55 to 58 per t acid is obtained, it became necessary, for most uses which the acid was put, to concentrate it to 48 deg. or higher. During the war, with the increased demand for highly concentrated nitric acid, particularly nitrating, the question assumed unusual importance. By simple distillation of an acid weaker than 68 per t, even when employing dephlegmators or changes in ssure, a concentrated acid cannot be obtained, beise, as Roscoe[4] showed, mixtures of nitric acid and er possess a minimum vapor pressure, or, what is ivalent, a maximum boiling point. At 760 mm. this t lies at 120.5 deg., with 68 per cent HNO_3, by ght, in the liquid and gas phases. As there is here stem of two substances whose liquid phases as well gas phases are miscible in all proportions, it is posle to achieve by rectification only residues of 68 per t HNO_3, while the portion that distills over in the e of mixtures weaker than 68 per cent is, with ideal ification, pure water, and in the case of mixtures nger than 68 per cent, pure 100 per cent HNO_3.

n the early years of the war the Central Powers, because the high concentration process had not been technically perfected, principally for lack of proper materials of construction, obtained most of their concentrated nitric acid by converting weak nitric acid into sodium nitrate and decomposing this with concentrated sulphuric acid. This method is fraught with an extraordinary consumption of raw materials, since per ton of HNO_3 in the form of 48 deg. acid it was necessary to use 0.8 ton sodium carbonate and 1.5 ton sulphuric acid, producing as byproduct 1.8 tons sodium bisulphate. For this latter there was at first available no rational use, since the method of Berl[5] of decomposing bisulphate with lime-nitrogen to form ammonia and caustic soda or sodium carbonate was discovered too late to be applicable to war processes.

One way to superconcentrate nitric acid lies in the action of water-binding substances on the dilute nitric acid. Of all the substances proposed for this purpose, such as sulphuric acid, phosphoric acid, arsenic acid, polysulphates, etc., only concentrated sulphuric acid has come to be used technically, since it is available in unlimited amount, the question of raw materials for its manufacture has been solved, the reconcentration of the resulting weak sulphuric acid presents no particular technical difficulty, and the superconcentrating operation itself can be carried out in simple apparatus. In principle, this process depends upon the knowledge that in the ternary system H_2SO_4-HNO_3-H_2O the H_2O vapor pressure is strongly reduced by the H_2SO_4; and the HNO_3, by virtue of its high partial pressure, can easily be driven off in a highly concentrated form. This process is carried out technically by the so-called dry method, consisting in the distillation of a previously prepared nitric acid-sulphuric acid mixture from retorts, either discontinuously,[6] in stages,[7] or continuously by the application of external heat, and perhaps under a vacuum,[8] or the process is carried out in columns, either with external heating or with internal heating from counter-current hot air or gases from an arc fur-

nace,[9] in which the abstraction of water is effected by downward trickling sulphuric acid. Or, the process is carried out by the so-called wet method,[10] using steam as the source of heat which is blown into the bottom of a high column. In this case the nitric acid is driven out of a previously prepared mixture or one freshly formed in the tower, by the condensation and combining heat of the steam, while a sulphuric acid of about 70 per cent flows out at the foot of the tower.

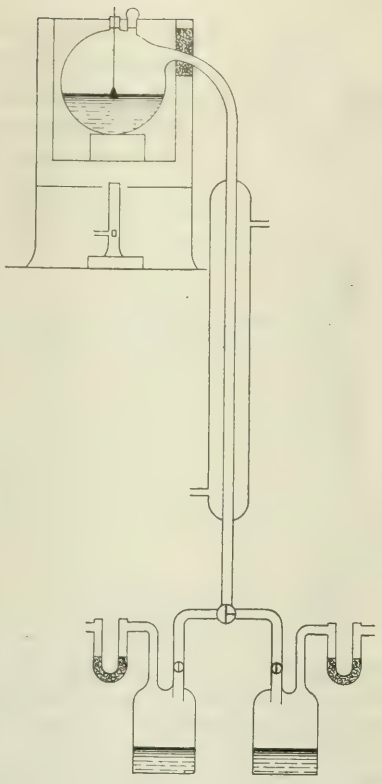

FIG. 2—DISTILLATION APPARATUS USED IN THIS INVESTIGATION

Despite the importance of the problem of superconcentration, only scattered articles appear in the literature, not only on the distillation of nitric acid mixtures but also of nitric acid-sulphuric acid mixtures. Besides the work of Roscoe already mentioned, the boiling point of the mixture with the lowest vapor pressure was determined by Mitscherlich as 120 to 121 deg., by Millon as 125 to 128 deg., and by Smith as 121 deg. C. Galle showed in a recent article[11] a graphical representation of a distillation curve of HNO_3 from a series of experiments by Guido Pauling. In Hausbrand's "Die wirkungsweise der Destillier und Rektifizier-apparate" (1921) is found a table and a graph of the vapors given off by nitric acid-water mixtures, in both cases for acids under 68 per cent. Smith[12] investigated acids above 1.5 specific gravity, and determined the boiling point of a concentrated acid of 1.517 sp.gr. to be 84.4 deg. Creighton and Githens[13] determined the boiling points of nitric acid-water mixtures at various pressures, as did also Pascal and Garnier,[14] who in addition gave a boiling point and condensation point curve for nitric acid.

Saposchnikow[15] investigated the vapor pressure and composition of the vapors of mixtures of nitric acid of 1.52 and 1.48 specific gravity with varying amounts of concentrated sulphuric acid, as well as the specific gravities and conductivities of these mixtures, the influence of water on the vapor pressure at room temperature, and the nitrating action of these acids. The results of the investigation are obscured by an appreciable NO_2 content in the mixed acids.

Pascal and Garnier (above) determined the vapor pressures of nitric acid-sulphuric acid mixtures at various pressures, as well as the boiling points and the vapor compositions. In a further research[16] these investigators reported the specific gravities of these mixtures and in a third[17] the specific heats. C. de la Camine[18] made a study of the heat balance in the distillation of a nitric acid-sulphuric acid mixture.

Independently of these last-mentioned researches, which were available (partly in short references) to us only very recently, and as a preliminary part of continued researches extending back to 1916, carried out by R. Leiser, the boiling point and distillation curves of nitric acid and the distillation and condensation curves of various mixed acids in the whole region of the Gibbs triangle were determined, in order to arrive at an understanding of the phenomena in the superconcentration of nitric acid.

Distillation of Nitric Acid-Water Mixtures

The purest nitric acid was used in the distillations prepared from technical nitric acid by distillation which freed it of various impurities. It was diluted with water to the various concentrations used. In preparing the highest strength of nitric acid a vacuum apparatus was used, shown in Fig. 1. In this it was possible, using five parts of concentrated sulphuric acid to one part of 65 per cent nitric acid and adding some ammonium sulphate (to decompose the NO_2), to obtain at 15 to 20 mm. pressure, in the first portion of the distillate, 100 per cent HNO_3. The receiver had to be strongly cooled, as otherwise the acid, by virtue of its high vapor pressure and low boiling point (33 deg. at 15 to 20 mm. pressure), distilled off to the vacuum pump. By raising the temperature to 45 deg. the remainder of the nitric acid was obtained as 95 to 98 per cent condensate. The acid obtained in this manner, after proper dilution and analysis, was distilled in the apparatus shown in Fig. 2. Particular care was taken that no rectification occurred within the retort-like vessel, by which the results might be changed in an unknown way. The vessel was completely surrounded by an air bath, as well as the connection between the vessel and the condenser; this connection, in addition being wrapped outside the bath with asbestos as far as its bend. The first acid fractions distilling condense first in the descending part of the condensing tube. A window in the air bath permitted the boiling point to be noted and its temperature to be read.

The analytical determinations of the highly concentrated nitric acid necessitated particular care from the very beginning, because it is noticeably more hygr

opic than sulphuric acid and because, as a result of s high vapor pressure, it already begins to evaporate ordinary temperatures.

With acids of less than 68 per cent HNO_3 the results ssembled in Table I were obtained. The NO_2 content the distillate was in these always below 0.02 per cent, id a yellow coloration of the liquid was not detectable. With increasing HNO_3 content the boiling point regurly increases, reaching a maximum of 121 deg. with 68 per cent acid. At this point the original acid, the sidual acid and the distillate have the same compotion.

The distillation of 68 to 100 per cent HNO_3 mixtures ave the results shown in Table II.

In this, with increasing HNO_3 content, a more and ore noticeable decomposition of the acid and distillate ts in, despite a decreasing boiling temperature. The iling point of a 100 per cent acid, which to begin with as completely free from NO_2, was found to be 83 deg. evertheless with continued heating it rose slowly, due the resulting decomposition and the dilution of the ixture from the water formed therein. The data of ables I and II are shown in the distillation curve of Fig. and boiling point and condensing point curves of Fig. 4. hese curves, which have a completely regular course, not permit any conclusions with respect to the drates of aqueous nitric acid reported upon by

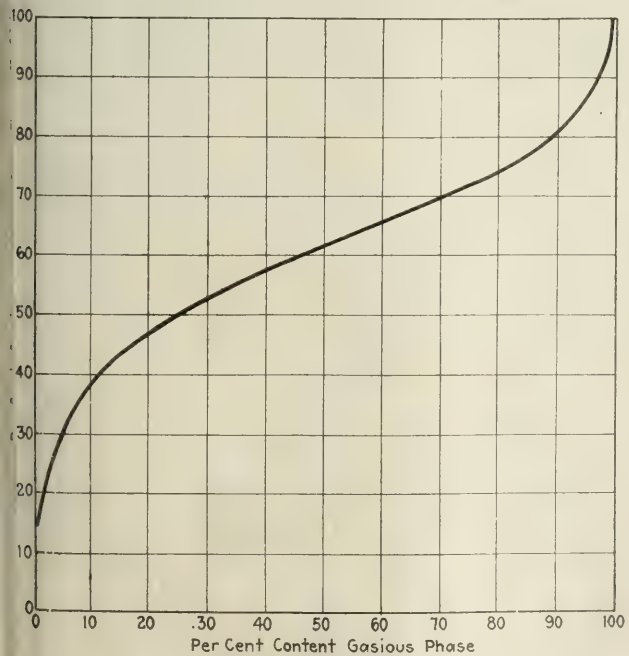

FIG. 3—DISTILLATION CURVE OF HNO_3

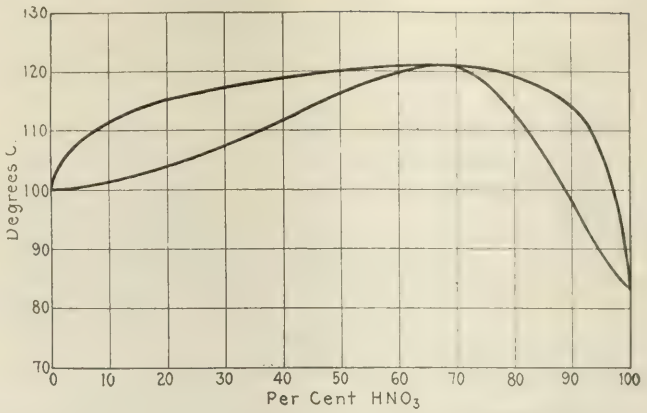

FIG. 4—BOILING POINT AND VAPOR PRESSURE CURVE OF HNO_3

Berthelot[19], Veley and Manley[20], Pickering[21] and Küster & Kreeman[22].

The distillation results at once become quite different if the evolved vapors are dephlegmated by passing them through a rectifying column. If this column is maintained at about 100 deg. with acids weaker than 68 per cent HNO_3, the mixture can be separated into a 65 to 68 per cent acid and an aqueous distillate. With acids above the eutectic point the column should be maintained at 83 deg. C., whereupon 68 per cent acid would be obtained in the residue and 100 per cent acid in the distillate. This principle is exploited in a series of patents[23]. A patent of Berl, taken out in the name of the Deutsche Gasglühlicht-Gesellschaft[24] proposes to convert acids containing less than 68 per cent HNO_3 into an acid of over 68 per cent by distillation with concentrated sulphuric acid, and then to separate this by rectification into an acid of 100 per cent HNO_3 and a 68 per cent residue. Nevertheless rectification is used technically only for pre-concentration, usually for a separation of the original acid into a 55 to 65 per cent residue and a 3 to 5 per cent distillate, since the ideal result of a separation into the eutectic mixture and pure water is not attainable with the apparatus technically available. In order to obtain a residue with 65 per cent HNO_3 or more in practice, it is necessary to accept also a strongly acid distillate. The desired advantage of conversion to a higher strength of acid is hence neutralized by the obtainment of large amounts of strong distillate acid, whose utilization cannot easily be accomplished.

Distillation of Nitric Acid-Sulphuric Acid Mixtures

In the course of this work the phenomena were studied which accompany the distillation of nitric acid-sulphuric acid mixtures, acids being used which contained no, or only a little, nitrogen peroxide. In a further communication the behavior of acids with a high NO_2 content will be reported upon. In these distillations the same apparatus was used that is shown in Fig. 2. The acids were analyzed by the method of Lunge and Berl given in "Chemisch-technischen Untersuchungs Methoden" Vol. 1, p. 878 (1921) and in "Taschenbuch f.d. anorganisch-chemische Grossindustrie," p. 256, using a Berl pipette (*ibid.*, p. 870 and 188).

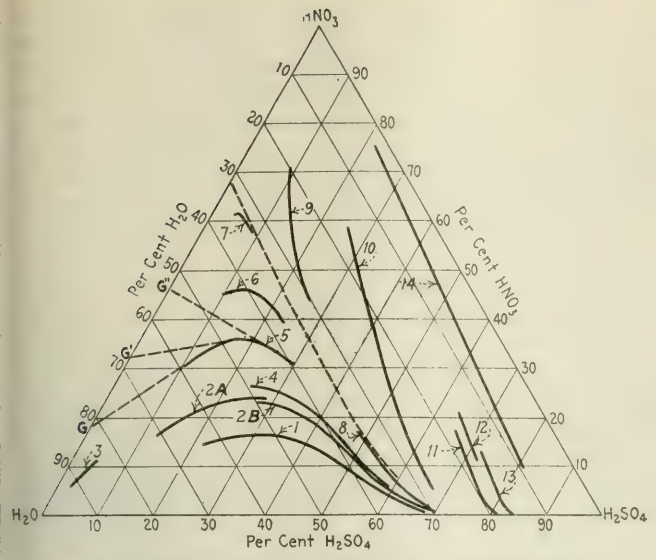

FIG. 5—DISTILLATION CURVES OF H_2O-HNO_3-H_2SO_4 MIXTURES

During the course of the distillation samples of acid were removed from the distilling flask with an arrangement modeled on the Lunge acid pipette, while simultaneously the three-way cock was turned to the second receiver. Two distillations in the same series were always made.

First, a series of experiments was carried out on acids with a high water content. The results are shown in Tables III to X, and graphically in Fig. 5.

At the start of the distillation of acid mixtures with more than 32 per cent H_2O a strongly aqueous distillate first comes over, whose HNO_3 content is lower than that of the acid in the still. The vapor pressure of H_2O in this region is strongly manifest and is only slightly influenced by the presence of H_2SO_4. A water-binding action of the H_2SO_4 does not become evident; which results in the fact that the H_2O content of the residue regularly decreases because of the distilling over of a dilute but increasingly stronger nitric acid. The distillation curves of Fig. 5 show at the start an inflection which lies at a point where the HNO_3 contents of the distillate and the residue are the same. Above this point, moreover, there comes over a distillate increasingly stronger in HNO_3, until finally a new point of inflection is reached in the curve, beyond which the HNO_3 content of the distillate regularly and very rapidly decreases. In the meanwhile the boiling point of the acid mixture rises so high (165 deg. and higher) that small amounts of H_2SO_4 come over. It is not possible, therefore, to drive off the last traces of HNO_3 free from H_2SO_4.

The phenomena with acid mixtures containing less than 32 per cent are different, as may be seen from Tables XI to XVI.

In this region (see Fig. 5) the distillation curves throughout most of their length approximate straight lines which do not vary very much from the straight

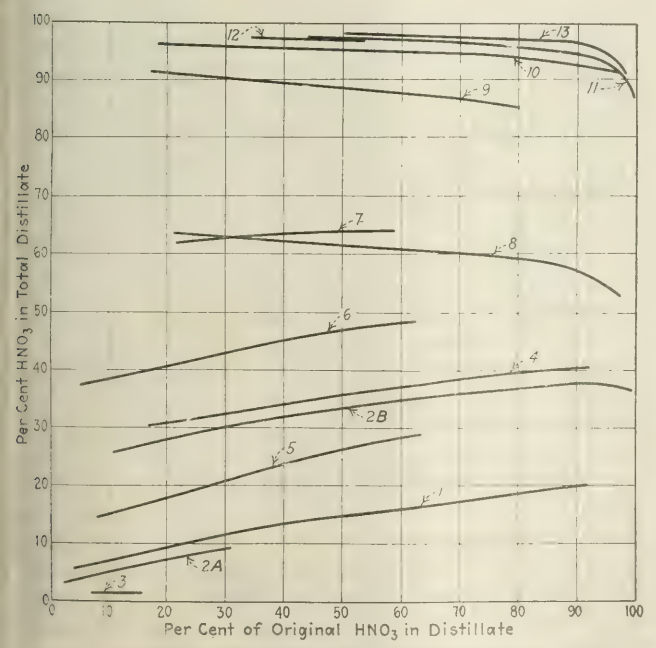

FIG. 6—HNO_3 DISTILLED AS A FUNCTION OF THE ORIGINAL HNO_3 CONTENT

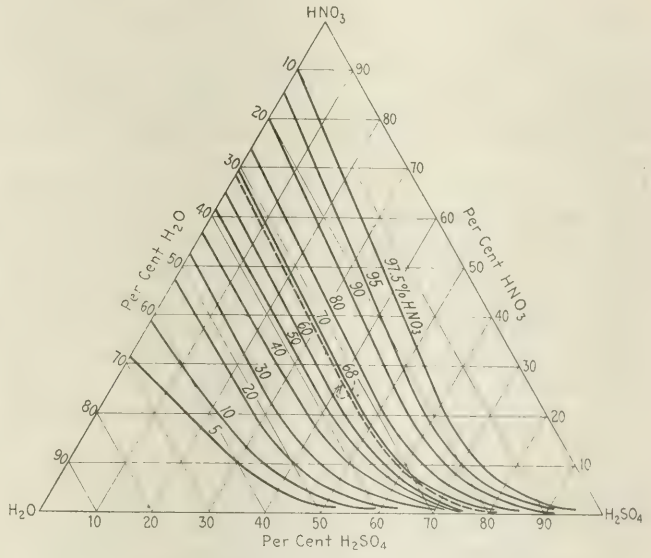

FIG. 7—COMPOSITION OF VAPORS FROM BOILING H_2O-H_2SO_4-HNO_3 SOLUTIONS

lines expressing H_2SO_4 : H_2O ratios in the various mixtures. At the very beginning of the distillation, owing to the strong water-binding action of the H_2SO_4, a strong distillate comes over, which, however, slowly decreases in strength, until, after most of the HNO_3 has been driven out, the curve breaks sharply, and thereafter a distillate more and more rich in water comes over. Through the rising boiling point of the mixture the water-binding power of the H_2SO_4 is so far lowered —i.e., the vapor pressure of the H_2O becomes so great— that greater amounts of H_2O go over with the distillate and strongly dilute it. H_2SO_4, also, distills over in the case of such H_2SO_4-rich and HNO_3-poor mixtures.

In Fig. 6 the HNO_3 content of the total fraction is graphically shown as a function of the percentage, in the total fraction, of the HNO_3 originally present in the mixture. The values are calculated by addition of the single fractions. It may be seen that in the case of the acids rich in H_2O (from 100 to 32 per cent H_2O content) the HNO_3 content of the distillate continually increases and only when the highly aqueous end fractions come over does it decrease (curve 2B). However, in this case no acid stronger than 68 per cent is obtained. In the case of the mixtures with less than 32 per cent H_2O, the strength of the distillate first slowly decreases, but when

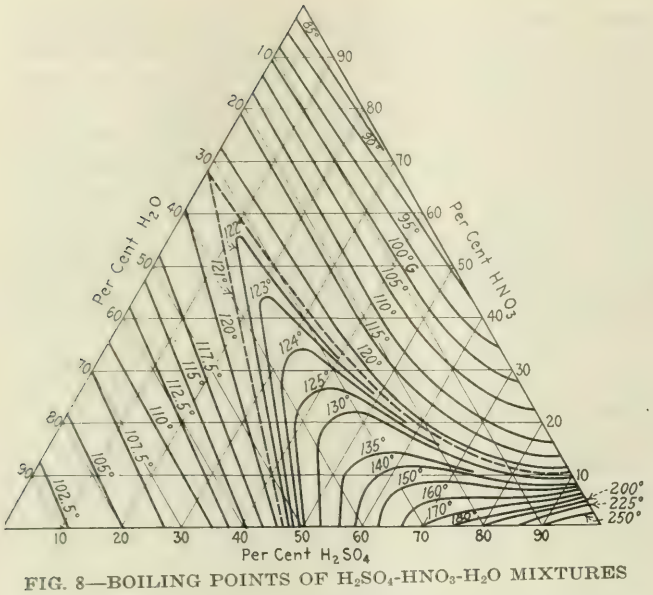

FIG. 8—BOILING POINTS OF H_2SO_4-HNO_3-H_2O MIXTURES

about 90 per cent of the HNO_3 originally present has come over, decreases more rapidly when the residual HNO_3 distills over, as is clearly evident from curves 11 and 13.

From the distillates obtained from the different mixed acids curves of mixtures evolving like strength distillates can be constructed in triangular co-ordinates, as shown in Fig. 7. Tangents to the distillation curves (Fig. 5, curve 5) produced to cut the H_2O-HNO_3 axis enable the HNO_3 content to be read directly as the distance H_2O-G; H_2O-G' or H_2O-G'', assuming, of course, that the distillate contains only H_2O and HNO_3, but no H_2SO_4. H_2SO_4 appears in the distillate from mixtures with a very low HNO_3 content.

As is evident from Fig. 7, the HNO_3 content of the distillate is almost a function of the H_2O content of the mixture, but this does not hold for mixtures low in HNO_3. Therefore, it is not practicable to superconcentrate strongly aqueous nitric acid solutions with concentrated sulphuric acid, because a relatively large amount of sulphuric acid would have to be used to reduce the H_2O content of the mixture as much as is necessary to obtain a mixture which would yield a high strength distillate. In that case a relatively great amount of dilute sulphuric acid would result which would require a greater heat consumption and heavier repair costs than if dilute nitric acid were preconcentrated by rectification, this preconcentrated acid were superconcentrated with a correspondingly smaller amount of sulphuric acid, and the resulting sulphuric acid were itself highly concentrated.

Thus, for example, to concentrate 100 parts 100 per cent HNO_3 from 35 per cent HNO_3 to 92.5 per cent HNO_3 would require 670 parts 96 per cent sulphuric acid. If the nitric acid were first preconcentrated from 35 per cent HNO_3 to 65 per cent HNO_3 the same 100 parts HNO_3 (excluding rectification losses) in the form of 154 parts 65 per cent acid would require only 147 parts 96 per cent sulphuric acid to be concentrated to 92.5 per cent.

In the first case there would have to be removed from the resulting dilute sulphuric acid, in order to reconcentrate it, 178 parts H_2O, while in the second case only 46 parts H_2O—namely, scarcely two-fifths—for the same amount of HNO_3 in the strong distillate.

In Fig. 8 the curves of like boiling points of the various acid mixtures are shown. In the region of acids rich in H_2O no particular influence on the boiling point is exerted by any one of the components. On the contrary, in the region of acids poor in H_2O and rich in HNO_3, the boiling point is strongly influenced by the HNO_3. For the H_2O-free HNO_3-H_2SO_4 mixtures the boiling points were determined in several experiments.

TABLE XVII.

H_2SO_4	33.3	60.0	75.0	80.0	86.0	94.0
HNO_3	66.7	40.0	25.0	20.0	14.0	6.0
Deg. C.	84.5	93.0	103.5	108.0	115.0	185.0

Such mixtures boil at comparatively low temperatures until an H_2SO_4 content of 90 per cent is reached (e.g., a mixture of 10 per cent HNO_3 and 90 per cent H_2SO_4 boils at 122 deg.). Further increase in the H_2SO_4 content is, however, accompanied by a marked increase in the boiling point.

Effects of Breathing Carbon Dioxide

Experiments on the effects of breathing carbon dioxide have been conducted at the Pittsburgh, Pa., station of the United States Bureau of Mines under the direction of Dr. R. R. Sayers, chief surgeon of the bureau, and A. C. Fieldner, supervising chemist. About 2 per cent of carbon dioxide in oxygen produced a slight increase in lung ventilation but no subjective symptoms; 5 per cent in oxygen caused an increase in lung ventilation of about 100 per cent, but no other signs or symptoms; 7.2 per cent produced about 200 per cent increase in lung ventilation, and moderate perspiration and a slight fullness in the head were experienced after breathing the mixture for 10 minutes; 9 to 10 per cent produced about 300 per cent increase in lung ventilation, and the subject complained of frontal headache and was dizzy and perspiring at the end of 10 minutes. About 9 per cent of carbon dioxide in oxygen was breathed by some of the subjects for as long as 45 minutes, but the breathing was very laborious, and dizziness, headache and perspiration were marked. In fact, to have done any work while breathing this mixture would have been extremely difficult.

Oxidation of Incidental Minerals Found in Clays

The purpose of an investigation being conducted by the Bureau of Mines at the ceramic experiment station, Columbus, Ohio, is to obtain fundamental data concerning the action of the incidental minerals found in clays during firing and, later, to make application of the information so obtained to explain certain phenomena that occur with the clay body. It is hoped to throw light on the physical, chemical and thermal changes taking place in clay bodies between a temperature of 400 deg. and 800 deg., the so-called oxidation period. The work is part of the industrial kiln investigation conducted in co-operation with the four heavy clay products associations—common brick, face brick, paving brick and hollow building tile associations. Data have been obtained on the dissociation and oxidation of sulphides found in clays. The work, it is hoped, will afford information on the so-called "scum" developed on some red bricks. Data for time, temperature and atmosphere curves have been worked out in reference to the oxidation of the carbonaceous matter found in clays. Clays have been distilled and the products of distillation studied. Application of the data to a study of the so-called "bloating" of clay products is being made.

The B.t.u. Chart

By Charles J. Lohman, Jr.
University of Cincinnati

THE commercial analysis of coal concerns itself chiefly with the caloric value, or British thermal units, per pound of coal. The B.t.u. determination is important, therefore, first, as a basis for knowing the actual heat value of the coal; second, as a means of comparing various coals.

The determination is usually made on a partly dried sample, and the results are reported on the actual basis and the dry basis—the dry basis being the basis of comparison.

The calculations required are greatly simplified by using the same weight of sample for each determination, or by referring results to the 1-gram basis. The calculations then reduce to these forms:

B.t.u. (actual basis) $= (ET - H)\ (1 - M')$

B.t.u. (dry basis) $= \dfrac{ET - H}{1 - M''}$

E = Calorimeter factor

T = Temperature rise corrected for radiation and thermometer correction

H = Correction for fuse wire, sulphur and nitrogen

M' = Gross moisture, or loss in weight due to first drying.

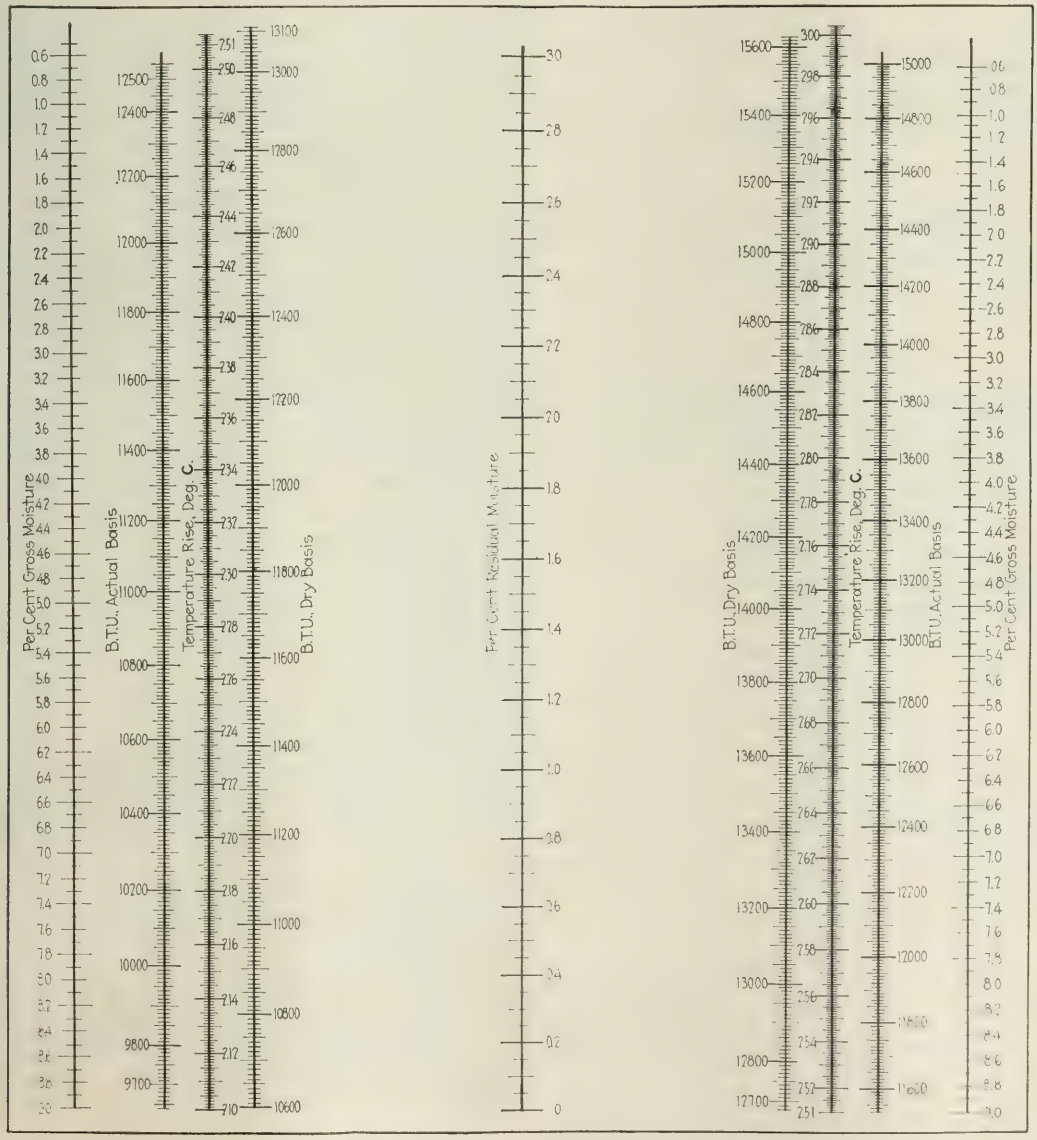
M'' = Residual moisture, or loss in weight due to second drying.

H is usually considered constant in the ordinary commercial analysis. E is practically constant, as there is very little corrosion, even in the nickel-lined bombs.

Where a large number of determinations are made, quite a little time is required to make the necessary calculations, as the numbers involved are too large to be handled with the ordinary 12-in. slide rule. The accompanying chart was therefore devised, to make the calculations quickly, as well as to eliminate the chance for errors.

The middle axis is scaled off in log $(ET - H)$, and is graduated in the equivalent temperature rise. The chart is constructed for the calorimeter factor, 5070, a correction of 53 B.t.u. being made for fuse wire, sulphur and nitrogen.

To use the chart, lay a straight edge across the chart so that it intersects the "temperature rise" and one of the "per cent moisture" axes at the values determined. Where the straight edge intersects the intervening axis, read the result in B.t.u. The chart is accurate to ±5 B.t.u., which is all the accuracy that is required.



Native Oil Production In Western China

Extraction Processes, Uses and Economic Importance of Native Chinese Vegetable Oil Industry—Nut Oils, Seed Oils and Soy Bean Sauce Manufacture—United States Takes the Largest Amount of the Exported Product

By H. K. Richardson

THE PRODUCTION of vegetable oils is one of the most important native industries in the Province of Szechuen, Western China. Almost any kind of seed or nut that will yield oil is made to give up that oil for some purpose or other. Only those oils that are obtainable in the native shops are listed below. The order followed under each heading indicates approximately the local economic importance of the oil.

Vegetable Seed Oils

T'sai Yu or Ching Yu, vegetable oil, is obtained from the seed of a cabbage grown for its seed only. This oil is erroneously called rape by foreigners. It is the common cooking oil of the common people.

Hsiang Yu, fragrant oil, from sesamum seed.

Peanut oil.

Cottonseed oil.

Tea oil, from the seeds of the tea flower.

Castor oil.

Soy bean sauce, a high-grade cooking oil made from soy beans and wheat, by fermentation.

Nut Oils

T'ung Yu or chinawood oil. This is the most important export oil of Western China.

Walnut oil made from the kernels of the english walnut tree.

Mineral Oils

It has been reported many times that crude petroleum is obtained along with the brine in the deep salt well districts of Tzuliutsing. During a stay of several days we failed to see any evidences of crude oil. Close questioning of natives and resident foreigners failed to reveal anyone who had seen this kind of oil. Oil may exist in this territory, but its quantity must be small when it has not materialized in the drilling of about 20,000 wells to a maximum depth of 3,400 ft.

Vegetable Seed Oils

The methods of obtaining oils from seeds are three: Pressing, water extraction and fermentation.

Since the *T'sai Yu* is the most common oil, the technique of its manufacture is the most thoroughly worked out. The process used for the extraction of this oil will be described in detail. Where the details of production of an oil differs from the *T'sai Yu,* these differences only will be described.

T'sai Yu, or Vegetable Oil

The process described was observed in a custom mill outside the city of Chengtu, capital of Szechuen Province. The seed was ground to a paste between millstones. The paste was steamed over boiling water for an hour and then pressed in a wedge press. The press cake was broken up, steamed and pressed again, the residue being sold for fertilizer. The extracted oil was settled, filtered through coarse grass paper and the clear oil marketed. From 600 lb. of seed about 120 lb. of oil was obtained from the first pressing and 80 lb. from the second. Thus the percentage of oil recovered to seed used was 33⅓ per cent. Consular reports from other parts of China show recoveries ranging from 34 to 45 per cent with 7 to 8 per cent oil remaining in the cake. Hosie[1], apparently describing this same mill, gave the yield as 32 per cent. His figures were obtained 15 years before ours, showing that there had been no change in the process in that time.

FIG. 1—GENERAL VIEW OF WATER GATES OF CUSTOM MILL OUTSIDE CHENGTU

The apparatus in this mill is typical of that in common use. While crude in construction, it serves its purpose well and cheaply.

The grinder consisted of two millstones about 4 ft. in diameter, and 9 in. thick. The upper stone rested upon the lower and was prevented from revolving by ropes attached to upright posts. The seeds were poured into a wooden hopper placed over a square hole in the upper grindstone and fed automatically to the grinding surface. The lower stone was driven at 28 r.p.m. by a water wheel attached to its base. The irrigation stream furnished the power. Fig. 1 is a general view of the mill. Fig. 2 is a photograph of one of the four grindstones at work. Fig. 3 gives a clearer idea of the setup of the machinery. The grinder had a capacity of 1,680 catties, or 2,240 lb., of "rape" seed per 24 hours.

The steamer is a large wooden tub with a woven bamboo sieve bottom set down over an iron pan 4 ft. in diameter and 1 ft. deep, containing boiling water. The vat holds a half ton of crushed seed, enough for two press loads. Fig. 4 gives a cross-section of the steamer.

The steamed ground seeds are packed into iron rings 1¼ in. high and 18 in. in diameter. Rice straw on top and bottom permits the seed to be made up in plinths 3 in. thick. Twenty-eight of these rings, each holding 15 to 20 lb. of crushed material, are placed in a wooden wedge press. As the wedges are driven in, the oil

[1] Hosie, "Report on the Province of Szechuen," London, 1904.

trickles out into a vat under the press. The final pressure is obtained by iron wedges driven home with a battering ram. The press is permitted to stand over night under pressure. Filling a press and bringing up to pressure take a whole day. The first press cake is taken out, broken up and re-pressed after steaming. The oil from the first pressing is considered the better, but it is rarely kept separate from the second run. The construction of this press can be seen from Fig. 5, which is a photograph of such a press taken when operating on peanut oil. The total length of press is 16 ft.; the pressing space is 6 to 7 ft.

Some general information regarding the mill is of interest. The mill operates on a percentage basis, receiving three catties out of each 150 catties of oil expressed. This was paid to the mill owner as rental of the machinery and water power. The seed owner furnished labor and fuel for the steamer as well as all seed. The labor cost of grinding was 40 cash per 240 catties, or an equivalent of 8 cents per ton of seed.

The complete grinding wheel cost 12 taels, or $9 gold. The stones last 3 years. The water turbine blades and run are replaced yearly at a cost of about $1.50. The complete press cost installed about $25. Two presses expressed about 40,000 catties (53,333 lb.) of oil a year.

FIG. 2—WATER-POWER GRINDSTONES GRINDING RAPESEED

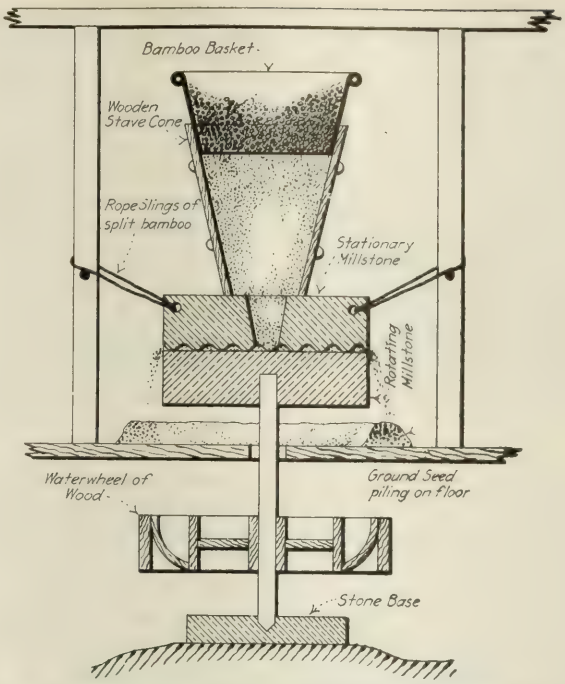


FIG. 3—CROSS-SECTION OF WATER WHEEL AND MILLSTONES

This *T'sai Yu* is the most useful oil in the Chinese economy. It is the principal cooking oil of the common people. The vegetables that accompany the rice diet are all fried in this oil. Until the advent of American kerosene it was the lighting oil of the province. Even today a rush wick dipping in this oil floating on water in a glass tumbler is the usual lamp in the wayside inns. In the cities there are few who can afford the foreign oil for lighting. For this reason the cotton-wick three-spouted copper-pewter lamps and the rush-wick earthen lamp still use *T'sai Yu* as the illuminant in the majority of homes.

This oil is erroneously called "rapeseed" by foreigners. Wilson[2] says that there is no true rape in Szechuen. He designates *Brassica juncea* and *Brassica campestris* as the members of the cabbage family that yield this seed. He estimated from his 11 years' experience that 75 per cent of all the oil produced in Szechuen came from these two plants.

Hsiang Yu, or Sesamum Seed Oil

This oil, called "fragrant" by the natives, is extracted by water, not pressed, from the seeds of *Sesamum indicum*. The white seeds are washed in cold water and

[2]Wilson, "A Naturalist in Western China," Doubleday, Page & Co., 1913.

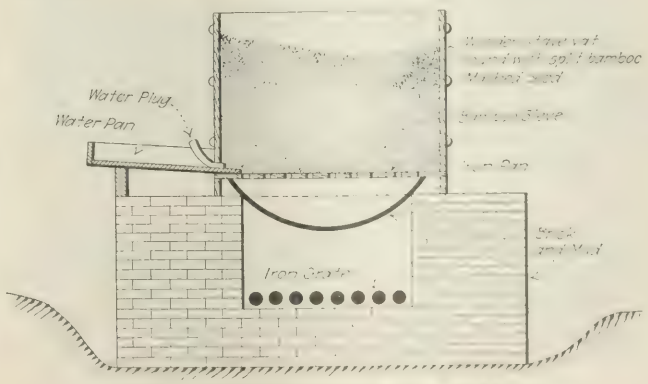

FIG. 4—CROSS-SECTION OF STEAMER

air-dried, after which they are roasted in an iron pan until they are light brown. They are then ground between millstones. Boiling water is added to the paste until no more is absorbed. The liquid mass is then lightly tapped with a weighted gourd, causing the oil to rise to the surface and the refuse to sink. The oil is poured off and the refuse removed and sold for feed for pigs.

The yield of oil is 40 to 44 per cent of the weight of the seed. In other parts of China the yield is reported to range from 50 to 57 per cent. The white-seeded oil is the most expensive edible oil in the province and is frequently adulterated with the cheaper *T'sai Yu*.

As far as the author is aware, this oil is the only one recovered by water extraction on a commercial scale.

Peanut Oil

Peanuts, *Arachis hypogœa*, grow profusely on the sandy river bottoms of Szechuen. Two varieties are grown. One, the native variety, resembles our Spanish peanut; the other is large, like the Virginia peanut, and was introduced into the country by the French priests. The oil is usually expressed from the smaller variety.

The whole peanut is roasted and ground up, shell and all, in a trough type of crusher shown in Fig. 6. The ground mass is then treated the same as we have described for *T'sai Yu*. The yield is about 16 per cent of the unshelled weight of nuts. The 40 to 43 per cent yields reported in consular reports from other parts of China must refer to the shelled nut.

Cottonseed Oil

Small amounts of cotton seed, *Gossypium herbaceum*, are pressed for their oil. The oil is looked upon as inferior and is used as an adulterant in the more highly esteemed oils.

Tea Oil

The seeds of the wild tea plant, *Camellia oleifera*, yield when pressed an oil whose principal use is for my Chinese lady's hair oil. The refuse cake has the reputation of taking out stains when used in wash water and of destroying the earth worms that attack rice plants. In the latter case the cake is mixed in the fertilizer for the paddies.

Castor Oil

The castor oil plant, *Ricinis communis*, grows to be a tree in the warm, humid climate of Szechuen. We had a plant in our yard that was 20 ft. high and 3 in. in diameter. The primary use for this oil is to moisten the colors used as stamp pads for the red Chinese seals or "Chops" as pidgin English has it. The yield is about 38 per cent of oil.

Various kinds of flax are grown in considerable quantities in the province. Fine hemp and ramie fiber is made. Except in case of the wild flax of the Tibetan frontier, the seed is used only as a birdseed. Probably the prevalence of wood oil has prevented the use of this seed for linseed oil.

Soy Bean Sauce

Soy bean sauce must be distinguished from soy bean oil, which comes mostly from Manchuria. This latter oil is expressed from soy beans mostly by modern pressure mills. When native methods are used, the process outlined for the *T'sai Yu* is followed. The yield is about 13 per cent of oil and a much-prized oil cake. Only a negligible quantity of this expressed oil is made in Szechuen. On the other hand, only 10 per cent of the beans raised in Manchuria is made into soy sauce, the remainder being expressed or shipped out whole.

In western China the soy bean, *Glycine hispida*, is extensively cultivated, but is used as a vegetable, for bean curd and for sauce. The soy bean sauce is the dark red sauce seen on the tables of Chinese restaurants in this country.

The process of obtaining soy bean sauce is one of fermentation and is long and complicated. Accurate information on this process is difficult to obtain. What follows has been pieced together from several sources. There are two kinds of soy: the red, or long process, and the yellow, or short process. The red soy is considered the better and is the only one found on the tables of good restaurants in China.

The process of manufacture extends over a period of approximately one year. The soy beans are first soaked over night in water and steamed for 5 hours. After thoroughly cooling, they are mixed with wheat flour and permitted to stand in a bamboo basket until a yellow mold appears—generally about 7 days. The mass is mixed with equal parts of water and salt in an earthen jar, covered and placed in the sun for 3 months, being stirred every day. By this time all the water has evaporated. For several months the jar is covered at night and stands open during the day. Finally, the black pickle is mixed with boiling water and thoroughly stirred. A bamboo basket sieve is placed in the top of the jar, the soy sauce passes through the sieve and is bailed out for 2 or 3 days. This is boiled with white sugar, seasoned with peppers and anise seed and is ready for use.

Twenty-eight pounds of soy beans yields 70 lb. of the soy sauce, according to Hosie[1]. The increase is due to the materials added in the process of making. This sauce is the foundation of all high-class Chinese cooking. It costs about 20 per cent more than the common "rape" oil. Very little of this material made in Szechuen is exported, for the large local demand takes care of the supply. A plant making this material looks like a drain pipe storage yard, for the big earthernware pots are set up close together, in an open courtyard.

Yellow soy is made by a similar process except that more water is added at the start and only 3 months is allowed for the complete process.

Nut Oils

Tung Yu, or Chinawood Oil

Chinawood oil, or as it is called by the Chinese, *Tung Yu*, is the most important export oil of interior China. Probably three-quarters of all the oil that reaches the United States comes originally from the Province of Szechuen. Most of the producing centers are at the eastern end of the post road from Wanhsien to Chengtu. It was our privilege to travel over this road a few years ago. The following description of how the Chinese obtain this oil is a composite of observations made on this trip and data picked up in nearby sections:

Chinawood oil is the product of a nut borne by the *Aleuritis fordii*. This tree thrives mostly on rocky soil, growing where nothing else will grow. It is found at about the 2,500-ft. elevation, although we have seen a few at higher levels. The fruits, which ripen in September, resemble smooth chestnut burrs and contain three to five nuts the size of good eating chestnuts.

To obtain the oil, the fruits are gathered just before ripening and stacked in piles until fermentation destroys the covering. Then the nuts are removed, dried and ground—shells and all—in a mill shown in Fig. 6. The ground mass is slightly roasted, then steamed and expressed in a wedge press like the one shown in Fig. 5. The yield of oil is approximately 40 per cent.

The roasting is done in shallow iron pans, 3x8 ft., set in brickwork over a coal fire. Usually a 2-in. layer of the ground seed is heated. The grinding is accomplished in a stone trough grinder such as is illustrated in Fig. 6. This type of grinder is used for all seeds with a hard coating as well as for rice hulling. They are operated by animal power as well as by man power. The construction is more clearly shown in Fig. 7, which is a top view of a small unit belonging to a peasant farmer.

The expressed oil is collected by the local merchants from the mills and sent over the post road to Wanhsien, from where it is transshipped by cargo junk to Hankow.

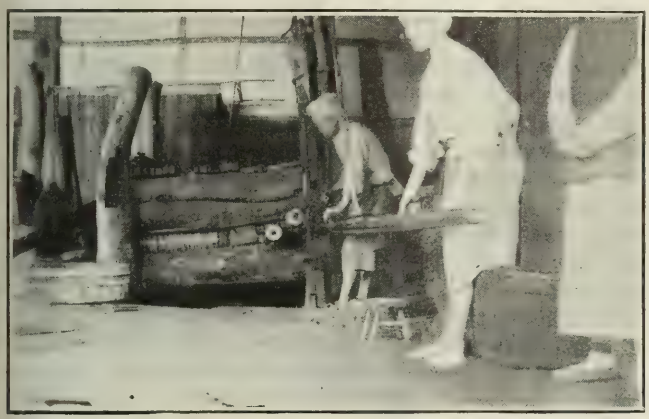

FIG. 5—WEDGE OIL PRESS SHOWING BATTERING RAM USED TO FORCE UP WEDGES

The method of packing is usually in bamboo wickerware baskets lined with paper. When oil is first poured into the paper lined basket the paper is wet, but no further oil is lost, because the oil does not filter through the paper used. A bottle of this kind holding 150 lb. of oil, suspended from a pole between two men, will be carried at the rate of 30 miles per day.[3]

The uses of the wood oil in the United States as a constituent of quick-drying cheap gum varnishes are well known. Its uses in China are manifold and less known. A few of these uses will be enumerated.

Native Uses for Chinawood Oil

All Chinese boats of the native pattern are given a thorough oiling with the wood oil. No other paint or preservative is used or needed. The putty used to calk the seams of these boats is made from a mixture of whiting, bamboo shavings and wood oil. It dries to a very hard material much superior to linseed oil putty. The oil when used for this purpose is boiled for an hour. This is the *pei yu* of the Chinese.

The first coat in painting a house or cheap furniture in China is a mixture of glue and pigment. This coat dries to a matt surface. The second coat is pure chinawood oil. The result is a fine glossy finish the color of the underlying dye or pigment. The oil used for this purpose is specially prepared. The crude oil is boiled

[3]The method of handling and financing this trade after it reaches Hankow is fully explained in *Daily Commerce Reports* for Feb. 9, 1921, p. 812.

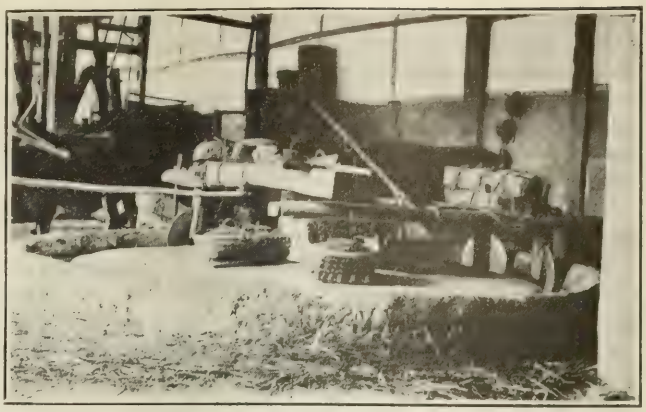

FIG. 6—CIRCULAR TROUGH GRINDER FOR WOOD OIL NUTS, PEANUTS AND HULLING RICE

up with an earth resembling fullers earth and powdered quartz. After boiling for some time, the clear oil is poured off from the sediment. This oil, called *Kuang Yu* —lustrous oil—by the Chinese, is the paint oil of the province.

Chinese lacquer, when applied in the pure state, turns to a jet black when dry. To make use of the valuable properties of the lacquer and avoid its black color, a large percentage of the lustrous wood oil is mixed with the refined lacquer. The result is a transparent varnish with most of the valuable properties of the lacquer. The greatest use for this varnish is for finishing furniture, especially that made in imitation of European goods. For this purpose it is applied as a second coat over a stain of the desired color. If no stain is used, the resultant color is a molasses brown. In either case the varnish retains the properties of lacquer in not showing hot water stains, resistance to scratches and long wearing qualities. It is contended by many writers that this use of the wood oil is an adulteration of the lacquer. However, the addition is for the definite purpose of extending the range of usefulness of the lacquer and should not be classed as adulteration.

The *Kuang Yu*—lustrous oil—is used alone upon furniture as a varnish. When applied to curly or knotted crotch or root wood, a very beautiful satin effect is produced. Sassafras wood is highly esteemed by the Chinese box makers on account of this valuable property. Unfortunately the light lemon color of the first days changes with age to a less pleasing darker shade. However, this is noticed only on the very light colored woods.

Lustrous oil applied to fabrics makes them waterproof. Cotton sheeting to which the oil is applied is used to protect bedding and goods when carried over-

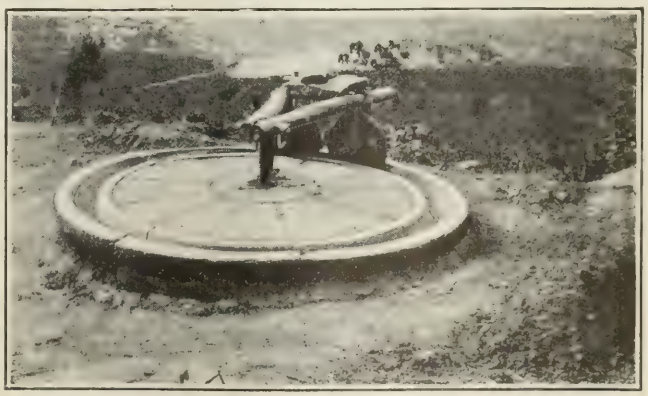

FIG. 7—SMALL-SIZED TROUGH GRINDER

land by coolies. Silk to which the oil is applied makes a fine, light waterproof material which seldom wets through, even in the driving tropical storms. The paper or silk of the native umbrellas is made waterproof by this oil. The use of the oil as a waterproofing agent has enabled the Chinese to get along nicely without rubber goods.

The best Chinese ink is made from the soot obtained by burning the wood oil in a confined atmosphere.

It is said that the wood oil is used in the producing regions as an illuminant. It is, however, so much dirtier and more expensive than the "rape" oil, or *T'sai Yu*, that its use must be limited. Its use has never come to the writer's attention.

Walnut Oil

In the mountain regions of northern Szechuen, the walnut, *Juglans regis*, the nuts of which are practically the same as our English walnuts, is used for its oil. Nothing is reported as to the process of extracting the oil. Much useful knowledge and information on the agriculture side of these oils can be found in Hosie[1] and Wilson[2].

Economics of the Oil Trade

The oils mentioned above are the source of a very large export trade for China. The extent of this trade can be seen from the data in Table I. The figures are for 1918, the last year for which complete data are available.

TABLE I—EXPORT OF VEGETABLE OILS FROM CHINA IN 1918

Kind of Oil	Exports in Pounds—Total	Exports in Pounds—To United States	Approximate Value
Bean, soy	303,622,000	284,900,000	$30,000,000
Cottonseed	17,773,000	16,665,000	1,500,000
Peanut	78,749,000	32,313,000	7,000,000
Rapeseed (*T'sai*)	740,000	486,000	44,000
Sesamum	2,753,000	658,000	165,000
Tea	3,137,000	165,000	198,000
Wood, tung	65,180,000	32,058,000	6,500,000
All others	14,920,000	3,196,000	9,000,000
Total	486,874,000	370,441,000	$54,407,000

This table indicates that China in all sections does an export trade of about $55,000,000 per year in vegetable oils. Probably not half of the total quantity produced is exported, so that the whole vegetable oil industry probably represents a yearly value of around $125,000,000, which makes it a large industry in China.

Exports Mostly Come to the United States

It is of interest to note that the United States takes about 75 per cent of the total exports. This percentage is increasing. The total trade is constantly increasing and is destined to be of considerable more importance to China as the years pass by.

The export of rapeseed oil is rapidly falling, having dropped from 4,345,000 lb. in 1916 to only 25,000 lb. in 1920. The increasing home consumption of this oil is given as the reason. In the few statistics that are available for 1920 there seems to be a healthy growth in most of the exportations.

Cyanuric Triazide as Primer

At the Pittsburgh, Pa., experiment station of the Bureau of Mines a study is being made of the properties of cyanuric triazide for the purpose of determining its suitability for use as a substitute for mercury fulminate in primers and detonators.

Cutting Massive Copper With the Electric Arc

By A. M. Candy

Arc Welding Engineer, Westinghouse Electric & Manufacturing Co.

IT MAY BE readily appreciated that owing to the great thermal capacity and heat conductivity of copper, it would be necessary to liberate a large amount of electrical energy if copper is to be fused locally, as is necessary for a cutting flame. An actual test showed that a 4½-in. square billet could be cut in 7 minutes using a current of 900 amperes. More massive pieces, such as sometimes result from a furnace accident, would require longer time.

Such a large mass or slab of copper was successfully cut up. The piece was very irregular in shape, but the approximate dimensions were 7 ft. long by 6 ft. 6 in. wide at the extreme points. In the central cut the thickness varied from approximately 1½ in. at the extreme end of the cut to approximately 7 in. maximum at the center of the cut. The average thickness over the 7-ft. length, therefore, would be approximately 4¼ in. This central cut through the slab was completed in approximately 5 hours.

For carrying on such work as this it is necessary to have available for the operator a direct-current generator which will deliver not less than 1,000 amperes through the arc circuit, developing approximately 60 volts. Current is regulated to the best value by cutting in various groups of resistances by an appropriate switch panel.

When carrying on such cutting work, using such large current values of 1,000 amperes, it is very essential

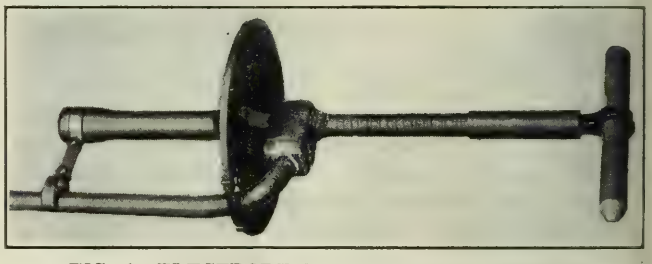

FIG. 1—ELECTRODE HOLDER FOR CARRYING EXTREMELY LARGE CURENTS

that the operator have his body thoroughly protected by closely woven clothing and wear leather gloves on his hands. The head and eyes should be thoroughly protected by a suitable helmet.

Among the most important items is that of an electrode holder which will have a sufficiently cool handle so that the operator can work continuously without experiencing discomfiture of his hands. Such an electrode holder is illustrated in Fig. 1. Current does not pass through the handle, but is carried by means of a supporting lug at one end of the handle and thence through a circular micarta disk and thence up to an aluminum casting at the rear end of the electrode holder proper. The handle is secured independently to the center of the disk, so that there is no metallic connection between the handle and the main portion of the electrode holder proper. By this construction the handle of the holder remains cool at all times.

The graphite electrode is gripped by iron "crows' feet" which are held tightly in place and in contact with the leading in circuit by a metal sleeve. A slight tap will tighten or loosen the combination, when it is necessary to adjust the carbon.

Principles of Blast-Furnace Practice*

"THERE are three principal objects in all blast-furnace practice ranking in importance in the following order—quality, economy and quantity. The first is essential. The second is commercially of great importance. The third is highly desirable, particularly in its bearing on the second. Therefore the object of modern practice is the attainment of the greatest possible quantity consistent with quality."

To justify this thesis, A. K. Reese cites four prime factors underlying the art—viz., preparation of materials, furnace design, auxiliary equipment and method of operation. He shows how each of them contribute to the desired ends.

Preparation of Materials

Satisfactory furnace operation requires an approach to uniformity in chemical and physical reactions throughout the whole cross-section in any zone. This in turn calls for correct distribution of the stock. To effect this much attention must be given to size and texture—coke must be strong enough to resist fracture during handling or crushing under load, and its density and size must not be so great as to prevent rapid combustion. It should be low in ash—since every pound of slag requires ¼ lb. of coke to melt it—low in sulphur and free from fines.

Perhaps the best chance of improvement lies in the preparation of the ore. It must be reducible and uniformly distributed. Dense magnetite may be greatly helped by an oxidizing roast. Few furnaces are troubled with an excess of massive lumps, but these must be crushed to 3- or 4-in. size, not only to allow enough surface so the surrounding gases may reduce the oxide before it enters the fusion zone, but also to permit correct distribution of the ore at the top part of the stack. On the other hand, fine ores clog the charge and produce an excessive amount of dust; they should be mixed with the dust and coke breeze and sintered. This not only produces a porous lump of proper size but also an ore very low in sulphur.

When the material shows not too great variation in size, the next problem is to get it into the furnace in the proper way. Since blast tends to hug the walls, there should be a slight excess of the finer material in this region. It can be placed there with a bell and hopper of correct design when keeping the stack constantly filled to the maximum height. A column of coarse charge surrounded by much finer material should always be avoided, because it would descend most rapidly due to rapid combustion of its fuel. Yet it smelts the slowest because the ore lumps are so large. Consequently half-smelted oxide enters the fusion zone. At the same time, fines along the wall move so slowly they chill and hang to the brickwork, slipping occasionally *en masse*, with pernicious results.

Lastly, air blast is a portion of the charge. It, too, must be as pure as possible and uniformly distributed. If tuyères are properly set, open, and receive an equal amount of wind, the distribution of the gases inside the furnace largely depends upon the condition and distribution of the charge (as outlined above). To get air as pure as possible, inlets to the blowing engines should not be adjacent to short chimneys, steam exhausts or cooling towers. Dry blast is an efficient method of controlling water vapor in the blast, and despite the fact that it has never been widely adopted, is an important factor in making uniform iron. It is impossible to operate with blast temperatures much above 1,300 deg. F. without causing an irregular descent of the ore column, except with dry blast. Given clean gas and modern stoves, the temperature can then be boosted to 1,600 deg. F. without difficulties.

*Abstract of a paper read before the autumn meeting of the British Iron and Steel Institute.

Furnace Design

Passing to the second prime factor underlying modern operations, Mr. Reese says that furnace design is largely a matter of correct adjustment of furnace lines. All the proportions are interdependent to a degree, but "the output capacity of a blast furnace, with any particular set of raw materials, is in proportion to the effective bosh area." He defines the "effective bosh area" as that portion of the full horizontal bosh area at its maximum diameter which is in normal activity. All the modern furnace lines are laid with the idea of keeping the walls clean and thus fully developing this area. Older furnaces about 80 ft. high often have maximum diameters of 19 to 20 ft. Modern, high-capacity furnaces about 90 ft. high have but a slightly larger corresponding dimension—20 to 22 ft. However, the bosh is much lower—in fact, below the zone of fusion. This prevents the pasty mass from scaffolding there. The bosh walls are also much steeper now—built at 80 deg. rather than 70 deg.—so that the material near the walls and above the tuyère line may not be chilled by being withdrawn from a supply of oxygen. Steep low boshes of course demand wide hearths—instead of the old 10 ft. diameter; we now build 16, 18 and even 20 ft.

In the old furnaces, the shaft above the bosh was vertical or had a very slight batter. Now we build a batter of 1 to 14 or 15 in order to provide more room for the free movement of the charge as it descends, gets hotter, pastier, and is compressed by the surmounting load.

A battered shaft means that the upper 20 ft. of the stack—the throat—must be plumb. It is now built slightly smaller in diameter than the hearth—small enough for efficient stock distribution, yet high enough for passage of gas at a velocity not too high. Material is not likely to hang up in this vertical throat, because it is dry and not yet hot enough to become pasty.

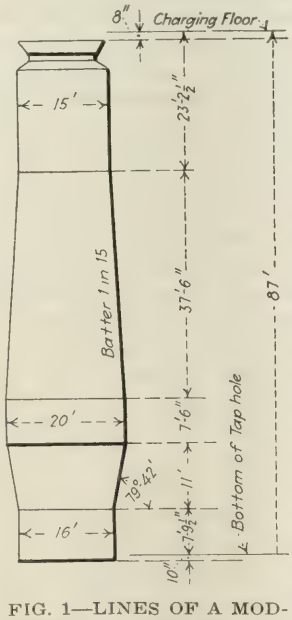

FIG. 1—LINES OF A MODERN BLAST FURNACE

Auxiliary Equipment

Auxiliary equipment comprises the third factor underlying progressive blast-furnace management. Chief among the auxiliaries are the blowers. They should be capable of compressing 40,000 to 50,000 cu.ft. of free air per minute to a pressure of 15 to 20 lb. and of delivering a constant volume under a long overload of at least 30 lb. Centrifugal blowers have been widely adopted since the development of an efficient volume governor, so the volume will not drop as the pressure increases. They are simpler, more compact, cheaper to

build and easier to operate than the reciprocating blowing engine and they deliver the wind without pulsations.

Top gas is discharged from three or four openings to downcomers of ample capacity. Many out-takes prevent channeling in the charge by gas seeking the shortest way out of the furnace. Large out-takes reduce the gas velocity and the amount of dust carried.

Equipment for cleaning this gas of all dust is essential. Burning a dust-free gas saves labor in cleaning boilers or stoves, saves costs for repairs and frequent renewals, permits more continuous and more uniform service through freedom from shut-downs, and permits a more compact redesign of stoves with smaller flues. The modern blast-furnace stove may therefore be made approximately 21 ft. diameter by 100 ft. high, with checker openings 3½ in. diameter, and still possess 80,000 sq.ft. of heating surface.

Efficient mechanical handling of the raw materials is necessary simply because the required number of tons of charge cannot be charged into the furnace by hand. The devices utilized are various—they all must handle the stuff without unduly crushing it or permitting segregation either in size or kind. Sand casting of pig is obsolete, because of the large amount of labor, floor space and clean sand required, and the heavy waste in scrap, either too light or too heavy to market. Furthermore, sand-cast pigs, when remelted, waste iron, fuel and furnace lining. Modern practice demands that liquid iron and slag be removed immediately from the neighborhood of the furnace.

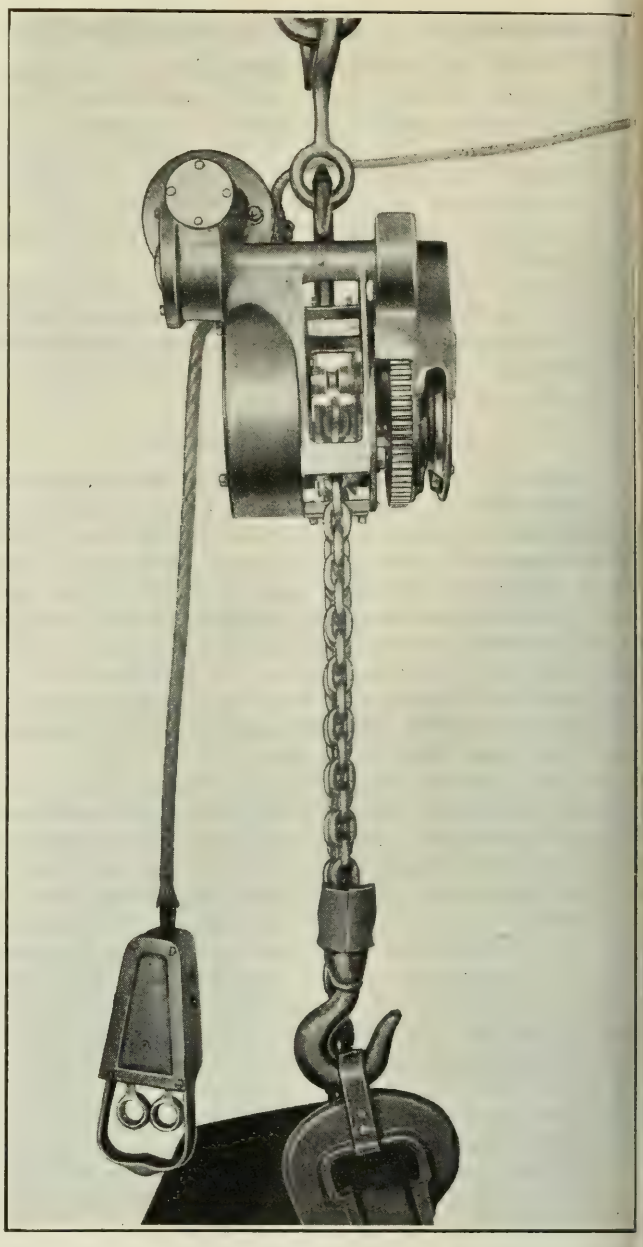
Finally, the fourth principle of modern practice—operating methods—is very hard to define on paper. Many details—such as tuyère location, amount of fuel or amount of cooling water required—are determinable only by experience with varying conditions of charge and weather. It is quite essential, however, that every effort be made to keep the operations steady—especially insuring that a constant *volume* of wind is delivered to the furnace, irrespective of furnace pressure or resistance.

The Motorbloc—A Motor-Driven Chain Hoist

An electrically operated material-handling device, known as the Motorbloc, has been placed on the market by the Motorbloc Corporation of Summerdale, Philadelphia. This new device has been developed to serve the operations lying between the well-defined field of the standard hand chain hoist and that of the traveling electric hoist, with the substantial overhead and electrical installation which its heavy duty requires. It is a readily portable hoist, which can be installed without preliminaries in any location where electric current is available. It is put in service with the facility of an electric drill or vacuum cleaner, and the self-contained pendent controller permits convenient operation as soon as the cord is plugged into the nearest electric circuit.

This hoist consists of a standardized chain hoist of steel construction, electrified by the application of a specially designed heavy-duty motor, proportioned reduction gearing and slip friction clutch, applied by means of a malleable iron supporting bracket comprising a self-contained electrifying unit, to which the pendent controller is also attached. In this way a simple mechanism has been developed for the electrification of the standard spur-geared chain hoist in capacities ranging from ¼ ton to 10 tons, proportioned to stand up under severe overloads.

The self-contained, pendent controller is easily



operated by the fingers of one hand, leaving the other hand free to guide the load. This arrangement makes it possible for one man, without physical effort, to accomplish what would otherwise require two or more men for lifting and placing the same load. The portability of the hoist is apparent from the fact that the 1-ton size complete weighs only 148 lb. The armature shaft and worm are carried in heavy duty ball-bearings, and provision has been made for adequate, automatic lubrication. The use of the ring-oiled slip friction clutch prevents damage from overrunning to the hoist parts and chain and at the same time completely protects the motor from overload, without the complication of an electric limit switch.

The accompanying illustration shows the Motorbloc built on a Franklin-Moore all-steel suspension spur-geared chain hoist. For occasional use at points where electric current is not available, or in the event of the temporary failure of electric power, the hand chain can be quickly applied, and the hoist operated as an ordinary block. While regularly furnished as a complete hoisting device, the self-contained electrifying unit can be applied to standard chain hoists already in service.

Tables and Charts for Natural Gas Users

By R. P. Anderson
Chief Chemist, United Natural Gas Co.

NATURAL GAS is one of the most important natural fuels. It has wide industrial use, particularly as fuel for heating furnaces and boilers and for operating gas engines.

Due to its former abundance and relatively low cost little attention has been given up to the present to its efficient use. Now, with the supply decreasing and the price rising, it has become worth while to devote time and study to this phase of the matter. The charts and tables which follow will be useful aids along this line.

Excess Air-CO_2 Curves and Tables

For the purpose of combustion study, natural gas may be considered as consisting of gases of the paraffine series only. When other gases are present in appreciable quantities, corrections must be applied.

In the actual combustion of natural gas, a certain amount of air in excess of the theoretical requirement for complete combustion of the gas must be present, and this quantity of air in the flue gas is known as "excess" air. If the theoretical maximum percentage of carbon dioxide in the flue gas is known (this is the percentage corresponding to perfect combustion without excess air), the percentage of oxygen in the flue gas corresponding to various percentages of carbon dioxide can easily be computed, and data of this kind have been compiled in Table I.

From the percentage oxygen in flue gas as found in Table I and a knowledge of the relation between the carbon dioxide formed and the oxygen requirement of natural gas of given specific gravity the percentage of excess air in flue gas containing a given amount of carbon dioxide can be computed. Such data form the basis of Fig. 1. The computation is made in the following manner: Assume the case of flue gas containing

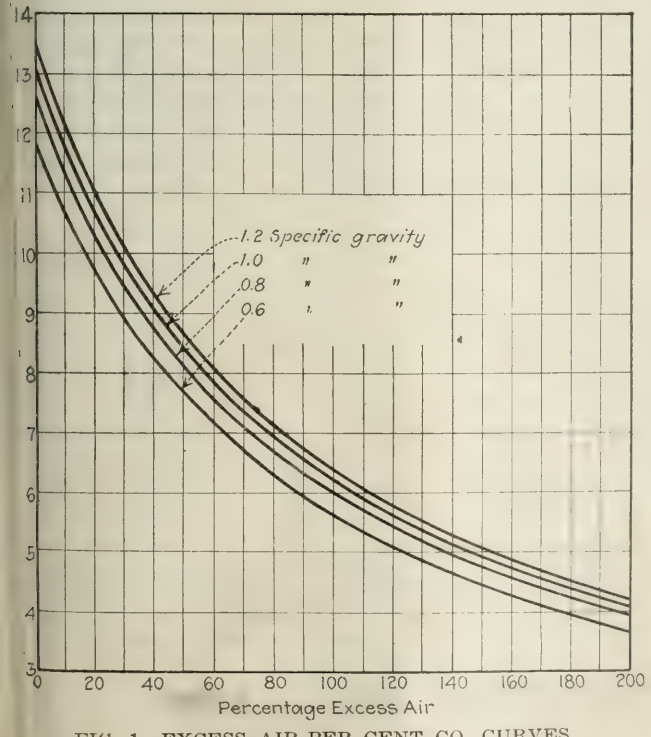


FIG. 1—EXCESS AIR-PER CENT CO_2 CURVES

TABLE I

Per Cent CO_2 in Water-Free Flue Gas	Percentage Oxygen in Flue Gas for Complete Combustion of Gas of Specific Gravity

4 per cent CO_2, produced from the combustion of natural gas of 0.70 specific gravity. By stoichiometrical calculation, 2.45 cu.ft. of oxygen is needed for the combustion of 1 cu.ft. of gas of specific gravity 0.70, and 1.30 cu.ft. of carbon dioxide would be formed. Then the formation of 4 cu.ft. of CO_2 will require 7.54 cu.ft. of oxygen. From Table I, 14.1 cu.ft. of excess oxygen accompanies every 4 cu.ft. of CO_2 and consequently the percentage of excess air will be $\frac{100 \times 14.1}{7.54} = 187$ per cent.

Heat Loss-CO_2 Curves and Tables

The losses of heat in flue gas may be classified under three headings: loss in flue gas proper, loss in excess air, and loss through incomplete combustion.

Heat Loss in Flue Gas—The loss of heat in flue gas proper is due principally, under ordinary conditions, to the heat of vaporization of the water vapor in the flue gas. The total heating value of natural gas in B.t.u. per cu.ft. at 60 deg. F., 30 in. mercury, dry, is given by the following expression, where n represents the average number of carbon atoms per molecule of paraffine hydrocarbons:

$$T.\ H.\ V. = 755.2n + 253.2$$

While the net heating value on the same basis may be found from the formula

$$N.\ H.\ V. = 704.8n + 202.8$$

the difference between the two formulas representing the heat of vaporization at 60 deg. F. of the water formed on the combustion of 1 cu.ft. of gas. If the natural gas contains only paraffine hydrocarbons, these heating values may be expressed in terms of the specific gravity (G) of the gas as follows:

$$T.\ H.\ V. = 1559.7G + 144.6$$

and $$N.\ H.\ V. = 1455.6G + 101.4$$

The difference between the total and the net heating value for natural gas of four different specific gravities is shown in Table II.

Column C—The data in this column represent the

200° F. Flue gas temp.

FIG. 2—HEAT LOSS-PER CENT CO_2 CURVES

percentage of the total heat in the gas that is lost in the water vapor formed on combustion.

Column E—The temperatures in this column correspond to the partial pressures of water vapor in flue gas, assuming a barometric pressure of 760 mm.

Column F—These data represent heat loss in flue gas constituents escaping at temperatures of column E rather than at 60 deg. F. Volumetric specific heat of nitrogen taken as 0.018 B.t.u. per cu.ft., of water vapor 0.022 B.t.u. per cu.ft., and of carbon dioxide 0.024 B.t.u. per cu.ft.

Column G—This column is the sum of columns F and C.

The loss of heat in flue gas proper, resulting from its leaving the appliance at a temperature higher than that of the entering air and gas, depends of course upon this temperature difference as well as upon the nature of the gas burned. It is generally desirable to cool the flue gas as much as possible before it leaves the appliance in order to avoid unnecessary heat losses, but where condensation of water in the appliance is undesirable, the flue gas must be allowed to leave the appliance at a temperature such that the percentage of water vapor in the flue gas will not exceed the saturation point.

It will be noted from Table II that this limiting temperature varies from 132 to 138 deg. F. if no excess air is present and that the heat loss which is unavoidable under these conditions amounts to from 9.7 to 11.3 per cent of the total heat of the gas, depending upon its specific gravity.

Heat Loss in Excess Air—The loss of heat due to excess air has been computed for different percentages of carbon dioxide for natural gas of specific gravity 0.60 and 1.00, and for flue gas temperatures of 200, 400, 600 and 800 deg. F. and the results have been shown graphically in Fig. 2. The volumetric specific heat of air was taken as 0.018 B.t.u. per cu.ft. in making these calculations.

Heat Loss Through Incomplete Combustion—The loss of heat through incomplete combustion of natural gas can be ascertained only through knowledge of the nature and quantities of the combustible constituents in th products of combustion, and this information is no usually available. Where combustion is nearly complete carbon monoxide may be assumed to be the principa combustible constituent of the flue gas and the approxi mate heat loss due to the presence of 1 per cent of thi constituent in the flue gas formed from the combustio of natural gas of 0.70 specific gravity will be abou 3 per cent of the heating value of the gas, if the flue ga does not contain much excess air.

The Danish Margarine Industry During 1921

The total number of margarine-manufacturing plant in Denmark in 1921 was 67, as compared with 64 i 1920 and 50 in 1919, according to an issue of the *Ber lingske Tidende*, published in *Commerce Reports* fo Aug. 14, 1922. The number of plants as compare with pre-war figures shows an increase of nearly 5 per cent. The greater number of plants have, howeve a comparatively small production capacity, as only of the 67 produce over 1,000,000 kilos per year, whil 39 have a yearly production of less than 100,000 kilo During 1921 the industry gave employment to 1,06 workers, of which 760 were men and 300 were wome or minors.

The production during 1921 amounted to 55,700,00 kilos, of which 6,400,000 kilos were from animal ingre dients while the rest was produced from vegetable oil The total value of the year's production is estimate at about 96,000,000 crowns. The 1920 productio amounted to 55,500,000 kilos valued at 146,000,00 crowns. The drop in prices was exceedingly heav during 1921. While during the normal years prior t 1917 there was an excess of imports of from 1,500,00 to 2,000,000 kilos per annum, the years following 191 have witnessed a very small importation. The import in 1919 amounted to 300,000 kilos; in 1920, 440,00 kilos; and in 1921, 508,000 kilos. Exportation durin 1919 amounted to 1,500,000 kilos; 1920, 2,300,000 kilos and in 1921, 506,000 kilos.

The total Danish consumption of margarine in 191 amounted to 58,000,000 kilos; in 1917, 33,200,000 kilos in 1919, 38,400,000 kilos; in 1920, 54,000,000 kilos; an in 1921, 56,000,000 kilos. In 1918, due to lack of ra materials, practically no margarine was produced.

The consumption of raw materials in the industr during 1920 and 1921 is shown by the following table:

RAW MATERIALS USED IN THE DANISH MARGARINE INDUSTR

Kinds of Oil Used	1920 Kilos	1921 Kilos
Oleomargarine	550,000	790,00
Premier jus	1,910,000	2,080,00
Neutral lard	430,000	500,00
Other animal oils	90,000	170,00
Total animal oils	2,980,000	3,540,00
Coconut oil	30,000,000	29,320,00
Palm fat	720,000	760,00
Arachid oil	1,580,000	1,240,00
Cottonseed oil	3,650,000	5,590,00
Sesame oil	4,590,000	4,180,00
Soy bean oil	2,640,000	1,540,00
Hardened oil	850,000	870,00
Total vegetable oils	44,030,000	43,500,00
Mixed oils	10,000	10,00
Grand total	47,020,000	47,050,00

Besides the raw materials enumerated above there ar used also in the production certain quantities of butte salt, milk and water from the use of which comes th difference between the quantity produced and the quan tities of raw materials used.

The production of margarine from animal material is fast decreasing while that produced from vegetabl matters is increasing.

Book Reviews

AZOTE. LA FIXATION DE L'AZOTE ATMOSPHÉRIQUE ET SON AVENIR INDUSTRIEL. By *L. Hackspill,* professor of chemistry at Strasbourg. Published by Masson & Cie., Paris. 275 pages.

The author demonstrates that there a national and world need for the nthesis of compounds of nitrogen and at such a process would accomplish tional security and economies in ace and in war. Each nitrogen cycle, tural and artificial, is carefully con-lered and its relative merits and dis-vantages are estimated. The experi-ental results obtained in France and other countries are freely discussed. The synthesis of ammonia is par-ularly well treated because of the ique qualifications of Dr. Hackspill. had had a personal acquaintance th the preliminary experiments of Chatelier and of La Rossignol upon so-called Haber process; he was sociated with M. Guichard in the nch investigations upon this process ring the war; and he has a friendly owledge of the Claude process. The sition as officer in charge during the nch occupation of the German Haber cess plant at Oppau enabled Captain ckspill to see and learn interesting ails which he now reveals.

t is popular and non-mathematical its style and may be understood by beginner in chemistry. It has the nch charm of perspicacity and pre-ion. RESTON STEVENSON.

RBUCH DER EISEN- UND STAHLGIESSEREI. By *Bernhard Osann, professor* at the Clausthal School of Mines. Fifth, revised edition. 693 pp., 758 illustrations. Publisher, Wilhelm Engelmann, Leipzig.

t would be useless to give a price o the book. The fourth edition, dated ty, 1920, cost 42 marks in paper or in cloth. A circular describing the h edition showed the prices 620 and 0 marks respectively, but before it d be issued a rubber stamp was ed showing the revised price to be 8 marks in paper or 950 marks n cloth bound. Since the cost of man marks at this moment is 1¾ s per hundred, the bound book at revised price would cost just 17 s in American money. However, will probably cost about $3.50 ugh an importer.

he fourth edition, which was re-ed favorably and at length by ard Moldenke in our issue for ch 23, 1921, was evidently very ular. The fifth, now at hand, has reset, but only very minor changes to be found. Brief notes on what happened in the 2 years are given by cutting out obsolete material he earlier edition. Fortunately for usefulness of the book to Ameri-, a new and much more extensive k accompanies the text.

Recent Chemical & Metallurgical Patents

American Patents

Issued Oct. 31 and Nov. 7, 1922

The following numbers have been selected from the latest available issues of the *Official Gazette* of the United States Patent Office because they appear to have pertinent interest for *Chem. & Met.* readers. They will be studied later by *Chem. & Met.'s* staff, and those which, in our judgment, are most worthy will be published in abstract. It is recognized that we cannot always anticipate our readers' interests, and accordingly this advance list is published for the benefit of those who may not care to await our judgment and synopsis.

1,433,533—Production of Arsenic.
1,433,634—Collecting Main for Coke Ovens.
1,433,654—Recovery of Sucrose.
1,433,655—Recovery of Sucrose.
1,434,047—Method of Uniting Metals.
1,434,089—Counter-current Washing Device.
1,434,090—Settling Apparatus.
1,434,650—Manufacture of Calcium Arsenate.
1,434,892—Manufacture of Vulcanized Rubber.
1,434,908—Process of Vulcanizing Rubber.
1,434,909—Process of Vulcanizing Rubber.

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Dehydrating Pyridine—In the refining of pyridine, the crude water solution is usually salted out to effect a preliminary separation of the water. For this purpose ammonium sulphate or sodium chloride may be used. The pyridine is not very soluble in the concentrated water-salt solution. The salt solution separates by gravity from the pyridine, in which it is immiscible. The supernatant pyridine, which is then drawn off, contains considerable water, often as much as 15 to 20 per cent. It is the purpose of the process described in the present patent to complete the dehydration in a practical and economical way. The crude pyridine solution is charged into a still and heated. The first portion of the distillate is a constant boiling mixture of pyridine and water, in the proportion of three mols of water to one of pyridine. This distillate is, therefore, much richer in water than was the original still charge.

The distillate is passed over a suitable soluble salt, such as ammonium sulphate. Ordinarily this salt does not complete the dehydration in the distillate, but is used because it is cheap and readily available in a byproduct coke plant. The vapors and condensate are passed over a mass of ammonium sulphate crystals to form a saturated solution, giving two liquid phases; one the saturated solution of ammonium sulphate and the other the pyridine from which most of the water has been extracted. This is passed into a separator, where the water layer is trapped out and from which the pyridine layer is returned to the still. The distillation and dehydration with ammonium sulphate are continued until the distillate no longer forms a water solution when in contact with ammonium sulphate crystals. When this point is reached, the charge in the still is completely dehydrated. (1,416,205, assigned to the Koppers Co., of Pittsburgh, Pa.; May 16, 1922.)

The Aluminum-Chloride Method of Cracking Petroleum Distillates—Probably the most important single patent issued in recent months is that granted to Almer M. McAfee, of Bayonne, N. J., and assigned to the Gulf Refining Co., of Pittsburgh. The patent has for its purpose the specification of a process of converting high-boiling petroleum oils into high-grade low-boiling products of the nature of gasoline, etc., by means of anhydrous aluminum chloride. The original application was filed Sept. 30, 1913, and the patent was issued Aug. 1, 1922.

The process may briefly be outlined as follows: A high-boiling oil is subjected to long-continued heat at a temperature below "cracking temperature" but sufficient to cause reaction to take place in the presence of aluminum chloride. Low-boiling products are formed which are removed from the reaction as fast as produced and proportionate quantities of fresh oil are added to maintain the volume and at the same time to keep the concentration of aluminum chloride practically constant. It is the claim of the inventor that, in contradistinction to the usual cracking methods, substantially complete results are obtained—that is to say, 80 to 85 per cent of the original oil reappears in the form of a water white, sweet, low-boiling oil of substantially saturated character needing little or no refining before being marketed as gasoline or kerosene.

The use of aluminum chloride in petroleum refining has been proposed by others, but it is stated that the results have never been entirely satisfactory, principally because the reaction conditions have never been carefully controlled. Aluminum chloride has a marked tendency to produce resin and tar, and in certain cracking processes in which it has been used, a very large production of gas and heavy oils has been obtained instead of a production of light oil, such as is desirable for motor fuel.

In the McAfee process, a substantially uniform concentration of aluminum chloride is maintained in the oil under treatment and the low-boiling

products formed by its catalytic action are removed from its sphere of influence as fast as they are formed, in order to prevent retrogressive changes. This is accomplished by feeding in new or fresh oil as fast as the low-boiling materials are removed from the reaction. Furthermore, the whole mass must be kept in vigorous agitation throughout the process, in order to prevent the formation of insoluble coky bodies by the aluminum chloride. Provision is also made to condense and return to the reaction the vapors of high-boiling oil, as well as any aluminum chloride which may itself vaporize. This is not only useful in maintaining the concentration of the aluminum chloride in the body of the oil, but also has the further advantage of condensing the gasoline being formed.

The particular temperature which is desirable in the oil mass will vary with the constitution of the petroleum oil being treated, but as a general rule the temperature will not rise above 500 deg. F., even in the case of very high-boiling oils.

The oils and apparatus should be free of water, air or dissolved oxygen. Both moisture and oxygen lead to the production of undesired side reactions as well as decomposing the aluminum chloride. The process may be used on any crude petroleum or on any high-boiling residual oil, such as fuel oil, still bottoms, etc. High-boiling distillates like gas oil and lubricating oil may be treated by the present process to make low boiling products. The aluminum chloride employed may be any commercial preparation, but should be anhydrous. (1,424,574. Aug. 1, 1922.)

Aluminum Alloy of High Strength—Francis C. Frary, of Oakmont, Pa., notes that certain aluminum alloys, containing about 4 per cent Cu, about 0.5 per cent Mg and with or without about 1 per cent Mn, are known to have very valuable properties; notably that by heat-treatment they acquire the tensile strength of mild steel and retain elongations of 10 to 20 per cent in 2 in. These alloys are very hot-short and are difficult to roll into sheets, cracks start at the edges and necessitate deep shearing and much discard. He finds that an alkaline earth metal cures this defect, retaining the other excellences of the metal, even increasing the facility of working in the cold. He recommends an analysis Cu 4.0, Mn 0.6 to 1.0, Mg 0.3 to 1.0, and Ca 0.3 to 0.6 per cent, remainder aluminum. Alloys of this family are easily made by melting ingot aluminum, 99 per cent pure, in a crucible with correct amounts of an 80:20 Al:Cu alloy and a 92:8 Al:Mn alloy, care being taken that the temperature does not exceed 1,500 deg. F. The crucible is then removed from the fire, a correct amount of metallic magnesium and an 80:10:10 Al:Ca:Cu alloy added, dissolved and thoroughly stirred. After reheating and skimming the alloy is cast into ingots. (Original 1,412,280, April 11, 1922. Reissued July 11, 1922, as No. 15,407. Assigned to Aluminum Co. of America.)

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Depilating Hides—The process set forth in the parent specification (Br. Pat. 175,314) for depilating hides or skins by means of gaseous ammonia in certain concentrations is improved by defatting the skins prior to or in the early stages of the ammonia treatment. In addition, the flesh sides of the skins are protected from the action of the ammonia, warmed concentrated ammonium hydroxide solution is used instead of steam to maintain the necessary degree of moisture in the chamber, the hides or skins and the gaseous or vaporous contents of the chamber are kept in relative movement and the unconsumed ammonia is expelled from the chamber by warm air or other warm gases which do not react with ammonia. The skins may be defatted by extraction with solvents, by saponification with alkali solutions or by regulating the temperature of the chamber in the initial stages of the ammonia treatment so as to effect saponification with the production of ammonia soaps. To protect the flesh sides, two skins may be placed in contact or the flesh sides may be provided with coatings impervious to ammonia. The unconsumed ammonia expelled from the chamber may be absorbed in cold water and concentrated for use in maintaining the required degree of moisture. (Br. Pat. 182,240. O. Richter, Brandenburg. Aug. 23, 1922.)

Synthetic Resins — Artificial resins produced by heating aldehydes with alkali are rendered stable toward water by dissolving them in a solvent and then precipitating them, preferably by water. If the initial resin has not been condensed as far as the hard stage, hardening may be effected by prolonged heating after the precipitation. The products may be used as protective paints for radiators, boilers, etc., being soluble in alcohol, benzene, carbon tetrachloride, trichlorethylene, acetone and fatty oils, such as linseed oil. They are also useful for the production of oil and spirit varnishes, impregnating or polishing solutions. According to the examples, (1) acetaldehyde and alkaline lye are subjected to continued heating after distilling off the volatile residue, the product dissolved in glacial acetic acid and then precipitated in powder form by the addition of water; after drying, the powder may be directly dissolved in a solvent to form a varnish or first converted by more or less prolonged heating into a resin of desired degree of hardness; (2) a viscous resin is formed from crotonaldehyde and alkaline lye, dissolved in acetone and precipitated by adding water; the precipitated resin is then hardened by heating it alone or dissolved in a solvent such as linseed oil. (Br. Pat. 182.459; not yet accepted. Consortium für Elektrochemische Industrie Ges., Munich. Aug. 23, 1922.)

Synthetic Resins—Diazo compou are incorporated with the resinous c densation products of phenols wh aldehydes or of ketones with aldehyd preferably before the condensation complete. The resulting materials resinous in character and can be u as oil-soluble dyestuffs, as a shel substitute, for electric insulation in pyrotechnics for making artifi flames; they may also be employed fat- and oil-soluble varnishes for pa textile fabrics and leather, or to p duce a bright, hard, polishable coat on wood, metals, etc. According to examples, (1) melted phenol and h amethylenetetramine are stirred gether, while diazotized *p*-nitraniline added; the product solidifies on cool to a green- or orange-colored oil-sc ble resin; instead of hexamethyle tetramine, formaldehyde, paraformal hyde or furfural may be used, wh cresol or other hydroxy-benzenes, chlorinated phenols, may replace phenol; (2) acetone and formaldeh are condensed by the aid of potash, diazotized *p*-nitraniline is then ad to the oily liquid. (Br. Pat. 1 497. H. Plauson, Hamburg. Aug. 1922.)

Ferric Oxide—Red iron oxide suita for use as a pigment is obtained heating ferrous chloride in a current air and steam. The ferrous chlori preferably in granular form obtai by evaporating pickle liquor while s ring, is spread on the floor of a mu furnace and air moistened by pass through water at 60 deg. C. is hea to 250 to 300 deg. C. and passed o it. The exit gas is cooled to obt hydrochloric acid, and the rate at wh the current is passed should be s that the acid condensed contains more than 30 grams HCl per 100 The gases leaving the condenser passed to a scrubber fed with water pickle liquor. Iron compounds deco posable under the conditions of process, such as hydrated ferric ox or ferrous carbonate, which may be the natural condition, may be mixed finely divided form with the ferr chloride, and in that case the tempe ture may be carried higher — instance, to 350 deg. C. There may a be added to the ferrous chloride sm quantities of salts having a cataly effect—namely, salts of copper, m nesium, tin, sodium and potassium. addition of a copper salt is stated improve the red color of the prod (Br. Pat. 183,323. D. Tyrer, Stockt on-Tees. Sept. 13, 1922.)

Dyeing Cellulose Acetate—Cellul acetate threads, films or fabrics, mixed goods containing it, are treat prior to or during dyeing, by me of trisodium phosphate solution. In example, acetate silk is treated at to 70 deg. C. in a bath of disodi phosphate and caustic soda. The trea silk may be mordanted with tannin a tartar emetic before dyeing. (Br. P 183,806; not yet accepted. Soc. Chimi des Usines du Rhone, Paris. Sept. 1922.)

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields
Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

merican Institute of Chemical Engineers Plans Big Program for Richmond Meeting

ifteenth Annual Convention Gives Promise of Important Technical Sessions and Interesting Inspection Trips

HE PROGRAM for the fifteenth annual meeting of the American stitute of Chemical Engineers has en approved by the Council. It will held in Richmond, Va., Dec. 6 to 9, th headquarters at the Hotel Jeffern. The New York delegation will go wn in special Pullman cars leaving e Pennsylvania Station at 8:45 p.m. d reaching Richmond at 7 o'clock the xt morning.

Materials of Construction

The feature of the technical papers ll be a comprehensive survey of maials of construction. Papers have en prepared on wood, chemical stoneare, glass, cement and lime and their e in chemical industries. In addition pers on such new developments as gnesium oxychloride, cement and ctile tantalum will be presented.

One of the outstanding papers of the ogram will be that of J. H. Young the Mellon Institute on "Asbestos-Protected Metal and Its Use." This presents several years of extensive estigation at the famous Pittsburgh boratory.

Attractions of Richmond

Mayor George Ainslie will welcome e Institute to Richmond, and Director Public Works Allen J. Saville will ake an address on the advantages hich Richmond offers to chemical dustries. The Institute will have opportunity to investigate these industries: The fertilizer plants of the Virginia-Carolina Chemical Co., the Richmond Car Works, the Standard Paper Co, and finally the industry which in e public mind is most intimately sociated with Richmond — tobacco.

An automobile excursion to Hopewell d Petersburg will include an inspection of some of the Hopewell industries in the morning, a luncheon and a drive ck through historic Petersburg in the ternoon.

The secretary of the Institute, J. C. Olsen, the Polytechnic Institute, Brooklyn, N. Y., will make reservations for the special Pullmans which go from New York to Richmond. Hotel reservations should be made direct to the Hotel Jefferson, Richmond.

The local committees have been very active and their energy and interest promise an enthusiastic meeting. The committees are as follows:

General Committee—John G. Armistead, chairman; W. T. Dabney, Dr. J. B. Robb, Graham Edgar.

Committee on Plant Visits—Dr. F. C. Carpenter, George H. Nash, A. G. Ryland.

Committee on Papers Concerning Richmond—Dr. Julius B. Weems, Dr. Samuel H. Sheib, Henry Froehling.

Committee on Entertainment—W. F. Rudd, J. G. Armistead, A. H. Allen, A. G. Ryland.

Committee on Hopewell-Petersburg Trip—John G. Armistead, A. H. Allen.

Gentlemen's Entertainment Committee—James F. Ryland.

Ladies' Entertainment Committee—Mrs. J. Allison Hodges.

Wednesday, Dec. 6

Meeting at Hotel Jefferson

9 a.m. Registration.

9:30 a.m. Address of welcome by George Ainslie, Mayor.

"The Advantages Richmond Offers to Chemical Industries," Allen J. Saville, Director of Public Works.

Symposium on Materials of Construction.

"Wood," J. V. N. Dorr, president of the Dorr Co.

"Application of Stoneware to the Chemical Industry," P. C. Kingsbury, chief engineer, General Ceramics Co.

"Ductile Tantalum," Dr. Clarence W. Balke, chemical director of the Fansteel Products Co., Inc.

"Magnesium Oxychloride," Max Y. Seaton, technical director, National Kellastone Co.

"Glass Rings—A New Filling Material for Towers," F. C. Zeisberg.

"Glass," A. E. Marshall. (One-half hour) Lantern slides.

12:30 p.m. Luncheon at Hotel Jefferson, $1.25.

2 p.m. Excursions. Optional trips.

1. Seeing Richmond.
2. Inspection of Standard Paper Manufacturing Co.
3. Richmond Car Works.
4. Southern Manufacturing Co. (baking powder).
5. Cheek-Neal Coffee Co. plants.

8:30 p.m. Reception and entertainment.

Thursday, Dec. 7

9 a.m. Business session. Canvass of ballots for officers. Reports of officers and Council. Reports of committees.

10 a.m. Papers.

"Effect of Rate of Flow on Absorption of Gases," Wallace B. Van Arsdel, chemical engineer, Brown Co.

"Resistance of Packing to Fluid Flow," F. C. Blake, E. I. du Pont de Nemours & Co.

"Absorption and Scrubbing Tower Design," R. T. Haslam, Massachusetts Institute of Technology.

"Integral Waterproofings for Concrete," Prof. A. H. White.

"The Density of Lime as a Function of Burning Conditions," Gerard Osterhof and Prof. J. R. Withrow.

"Defects of the Patent Laws in the United States," Maximilian Toch.

"Tobacco Industry of Richmond," Thomas M. Carrington, president Tobacco Association of the United States.

12:30 p.m. Luncheon.

2 p.m. Excursions.

Inspection of Allen & Ginter division of Liggett & Myers Tobacco Co. (cigarettes).

Whitlock branch P. Lorrilard Tobacco Co. (cigars).

Larus Bros. & Co. (smoking and chewing tobacco) plants.

8 p.m. Papers—Hotel Jefferson.

"Asbestos-Protected Metal, Its Development, Manufacture and Use," Dr. J. H. Young, senior fellow, Mellon Institute. (Illustrated by slides.)

"The Uses of Concrete in Chemical Works," A. C. Irwin, engineer, Portland Cement Association.

Friday, Dec. 8

9 a.m. Business.

10 a.m. Papers.

"Oil Substitution Products, W. B. Pratt.

"Some Engine Experiments With Oxidized Oils," J. H. James. (Lantern.)

"Use of Propane for Refrigeration," H. D. Edwards, Linde Air Products Co.

"A Method for the Analysis of Stirrer Performance and Its Application to a Common Type of Paddle Stirrer," J. C. Wood, E. R. Whittemore and W. L. Badger.

"Purification of Sewage by Aëration in the Presence of Activated Sludge—IV.", Edward Bartow.

"The Importance of Impurities," Jerome Alexander.

12:30 p.m. Luncheon.

2 p.m. Excursions.

Inspection of Virginia-Carolina Chemical Co.'s Richmond Chemical Works (complete fertilizers), Richmond Cedar Works (woodenware) plants.

7 p.m. Subscription dinner, Hotel Jefferson (informal), $4.

Saturday, Dec. 9

8:30 a.m. Excursion to Hopewell and Petersburg, where the following plants will be visited: The Stamsocott Co., Hummel-Ross Fibre Corporation, Hopewell Chemical Co., Water Purification System.

Fatal Explosion at Columbia Kills Graduate Student

William E. Spandow Instantly Killed and Reginald G. Sloane Injured by Bursting Autoclave

An accidental explosion Nov. 17 in the chemical engineering laboratories of Columbia University resulted in the death of William Eastman Spandow, a graduate student from the University of Denver, and in serious injury to Reginald Gordon Sloane, a Harvard graduate. The students were experimenting on a semi-technical scale in the manufacture of diphenylamine. The experiment was proceeding in a normal manner when suddenly the pressure mounted and before it could be released the top was blown off the heavy steel autoclave and shattered into pieces which were hurled in all directions, imperiling the lives of at least seven other students at work in the laboratory. Spandow, who was standing directly over the instrument in order to read the pressure gage, was hit by a heavy piece of steel which crushed his head, killing him instantly. Sloane had been assisting in the experiment and was a short distance from the autoclave when it exploded. He was painfully burned by the chemicals plastered over his face and eyes, his scalp and face were cut by flying missiles and he was badly bruised.

The force of the explosion was sufficient to do considerable damage, principally to the windows and glass apparatus and equipment.

Had Been Tested for 750 Lb.

The apparatus, which had previously been used for this and other experiments, was a heavy steel autoclave having a capacity of 2 gal. It was about 2 ft. high, 1½ ft. in diameter and had been tested for a pressure of 750 lb. per sq.in. The lid, about 2 in. thick, was held in place by twelve lugs, six of which were sheared off even with the flange. The bolts were broken or threads stripped on the others. The ... was broken into hundreds of pieces, the largest probably not weighing more than 10 lb.

The force of the explosion was mostly expended vertically. A large hole in the wooden floor of the balcony directly above the apparatus indicated the path of part of the flying steel.

The experiment on which Spandow and Sloane were engaged was the production of diphenylamine by the standard commercial method. Aniline and aniline hydrochloride were being heated at 240 to 260 deg. C. for 24 hours to form diphenylamine, ammonia and hydrochloric acid. This was one of a series of preparations which go to make up a course in the manufacture of dye intermediates and organic chemicals. Under the direction of Prof. Arthur W. Hixson this course has been one of the most popular in the chemical engineering school. Its purpose is to give the student experience in actual chemical manufacture on a scale approximating semi-commercial practice. This particular experiment, the preparation of diphenylamine, had been successfully carried out by students in the preceding classes. The aniline used was the commercial product taken directly from the shipper's drum. The aniline hydrochloride had been made by Spandow and Sloane from this same aniline and had been purified and thoroughly tested.

Sloane's Account of Accident

Spandow and Sloane began their experiment about 11 o'clock and were heating up the autoclave by means of the gas heater directly beneath it. The reaction was proceeding normally and by means of its valve the apparatus had been vented twice in order to remove any air or oxygen it contained. At about 12:20 Professor Hixson read the gage, which then showed a pressure of 112 lb., and after warning the students to turn off the gas in case the pressure increased, he started for lunch. Before he had left the building, however, the explosion occurred and he rushed downstairs and assisted the students in giving first aid to Sloane.

In giving an account of the accident Sloane said that the gage had shown a sudden rise of pressure, from 112 to about 250 lb. per sq.in., and that he had hurried to the cock 20 ft. away and turned off the gas supply. Returning, he saw Spandow opening the valve on the autoclave and apparently this act was followed by the explosion. The theory has been advanced that the flame, not yet completely extinguished in the gas burner, ignited the escaping gases and shot back into the chamber to cause the explosion.

Paint and Varnish Makers Meet

Four Associations Hold Conventions in Atlantic City

Well-attended and enthusiastic meetings characterized the convention of paint and varnish associations in Atlantic City, Nov. 15 to 17. The four national organizations of the paint and varnish industries—the National Paint, Oil and Varnish Association, the National Varnish Manufacturers' Association, the Paint Manufacturers' Association of the United States and the Federation of Paint and Varnish Production Clubs—held simultaneous conventions, and the opportunity for association and social intercourse offered by the assembly of so many representatives of the trade in "America's Playground" was no less valuable than the business sessions.

Business Good

Ernest T. Trigg, president of the National Paint, Oil and Varnish Association, sounded a keynote of optimism at the opening session of the convention, saying that in the 4 years since the armistice, American business has reached a degree of stability that it took Europe 40 years to reach after the battle of Waterloo. The whole business life of the present generation, said President Trigg, must be devoted to the task of world reconstruction to make good the wastes of the war.

"The paint and varnish industry," he said, "more than all others, as the industry of preservation, is the very incarnation, in spirit and substance, of the things needed to combat the waste of those years that were dedicated to destruction and waste."

Arthur E. Foote, of the division of simplified practice of the Department of Commerce, addressing the National Paint and Varnish Manufacturers' Association, expressed the desire of the Department of Commerce to co-operate with the trade. He stressed the importance of standardization in eliminating waste, saying:

"Business men should realize that the Department of Commerce is at their service and that the government's only object in creating the simplification of practice movement is to eliminate waste. Over one hundred different industries throughout the country are considering simplified practices, and when the tremendous value of this movement is realized there will be many more."

Industrial Alcohol

A resolution requesting the Commissioner of Internal Revenue to issue reasonable restrictions to insure ample supplies of alcohol to the industry was drawn up as a result of a report by committee of the N. P. O. and V. A.

Flaxseed Situation

A. C. Dilman, of the U. S. Department of Agriculture, discussed the flaxseed situation in this country as a factor of vital importance to the paint industry.

For the past 10 years, he said, production of flaxseed in the United States has averaged only a little over one-half the quantity consumed, so that considerable imports have been necessary.

Mr. Dilman told how this shortage can be overcome by growing combination crops of flax and wheat. He told of the successful experiments in this direction in Minnesota, and said that climatic conditions make similar combination crops possible in other states.

Election of Officers

Officers of the four associations were elected as follows:

National Paint Oil and Varnish Association: President, Louis R. Atwood; vice-presidents, E. V. Peter, J. W. Bray, Sydney Rasmussen, H. Kuhn, George Henderson; treasurer, John H. Pine; secretary, George Horgan.

National Varnish Manufacturers' Association: President, Henry L. Calman; vice-presidents, C. J. Roh, W. ... Carnegie.

Paint Manufacturers' Association of the United States: President, Charles L. Cook; vice-presidents, S. R. Matlack, Samuel Rosenthal; secretary-treasurer, G. B. Heckel.

Federation of Paint and Varnish Production Clubs: President, E. W. Fasig; secretary-treasurer, G. B. Heckel.

Weeks Recognizes Peace-Time Value of C.W.S.

War Secretary Points Out Important Sanitary and Industrial Applications of Poison Gases

Peace-time activities of the Chemical Warfare Service were discussed as follows by John W. Weeks, the Secretary of War, in the course of an address before the Boston Chamber of Commerce:

"Does the average citizen know that the deadly mustard gas, as well as several other war gases, is being employed experimentally with great hopes of its proving a valuable retardant in the treatment of tuberculosis?" Contrary to the popular impression that the poison gas causes respiratory diseases, he continued, it has been established that it tends to prevent such diseases. "Among the employees of large war gas factories, influenza and similar diseases were practically unknown during the period of the plagues that swept our country at the close of the world war. Extensive arrangements are being made in the laboratories of the Chemical Warfare Service to conduct research into the fields of medical employment of war gases and byproducts."

Extermination of Vermin

One of the greatest problems of modern sanitation is that of effective and safe fumigation. It is necessary to wage continuous war against the rats and other vermin which carry plagues. Only recently, in the fumigation of a ship in San Francisco, several men were killed and many injured by the fumes of hydrocyanic acid. The Chemical Warfare Service offered its co-operation and has already given promise of solving this problem. Tear gas was finally selected as the best possibility for use in fumigation. Near the end of October a test was made with a concentration of one-eighth the strength which would injure human life. Several officers spent the night in a room adjoining the kitchen which was selected for the test. The gas was projected into the kitchen in the evening, and the officers in the next room reported that they were not inconvenienced thereby. In the morning it was discovered that every mouse, fly, cockroach and other insect was dead. The gas was then projected into a large warehouse, killing hundreds of rats, mice, bats and other vermin. The experiment was repeated in fumigating a ship and the results were beyond expectations. The Public Health Service is enthusiastic about this work and the possibilities seem limitless.

Industrial Value

Tear gases have also been demonstrated as very effective in employment against barricaded criminals and in attempted jail deliveries and other riotous actions. The gas mask is becoming very valuable for use in mining activities. The Chemical Warfare Service has produced the only substance suitable for protection of miners against the deadly carbon monoxide gas. In their development of gas masks and suitable materials therefor, the scientists of the Chemical Warfare Service have made another valuable contribution to the industries in the form of a very active charcoal which is useful in manufacturing gasoline from natural gas and coal-tar products.

Boll Weevil Control

It is becoming recognized that any effective control of the boll weevil and similar pests must come from the use of these poisonous compounds. The Air Service is co-operating in experiments by spraying the fields and orchards with the vapors. Experiments are being conducted by the Chemical Warfare Service in co-operation with the Navy Department in hopes of producing a non-fouling paint and thereby avoiding the results of barnacles which gather on ship bottoms. Gases are being used in experiments with the hope of destroying the teredo and limnoria, which bore into submerged timbers in our southern waters. Finally, in addition to all of these constructive activities, one must recognize that the work of the Chemical Warfare Service has led the way to the foundation of an American dye industry that should one day be one of our most valued assets.

R. E. Swain Chosen for Chandler Foundation Award

Friends of Professor Chandler presented in 1910 to the trustees of Columbia University a sum of money which constitutes the Charles Frederick Chandler Foundation. The income from this fund is used to provide a lecture by an eminent chemist and to provide a medal to be presented to the lecturer in further recognition of his achievements in science. Previous lecturers on this foundation were L. H. Baekeland, W. F. Hillebrand, W. R. Whitney, F. Gowland Hopkins and Edgar F. Smith.

The lecturer this winter will be Robert E. Swain, professor and head of the department of chemistry, Stanford University. Dr. Swain's subject will be "Atmospheric Pollution by Industrial Wastes." The lecture will be in Havemeyer Hall, Columbia University, on Jan. 9, 1923.

Rose Polytechnic Institute Plans Mining Engineering Course

Philip B. Woodworth, president of the Rose Polytechnic Institute, Terre Haute, is developing plans for a course in mining engineering at the institution. A portion of the new college buildings will be assigned for this branch of study, which will be placed on an equal footing with the five other departments of the school. The Bureau of Mines will co-operate with the new department and Prof. R. L. McCormick, now in charge of applied mechanics studies at the college and active in mining engineering for 30 years past, is considered as the probable head of the new course of instruction. No definite date has as yet been established for the inauguration of the department.

Electrochemists Hear of Burma

Rangoon, Mandalay and Other Familiar Places Made Lively by A. C. Matheson

A regular meeting of the American Electrochemical Society was held in Rumford Hall on Friday evening, Nov. 17. The principal speaker, A. C. Matheson, gave a delightfully informal talk on his trip around the world. His trip had for its primary purpose the inspection of a silver mine in Burma.

Shipping from Marseilles, he went through the Suez Canal, where he saw the tremendous army base for the British Mesopotamian army. One extremely interesting point in connection with this place was the piping of Nile water from a tributary underneath the canal to supply the base with drinking water. This supply was carried along with the army in a piping system as it advanced into Palestine. There were pictures, too, of the rugged Arab boats which can be found throughout the African coast and even out in the Indian Ocean.

Ceylon Tea and Perfumes

Everyone knows of Ceylon tea, but few have heard of the perfumes. These seem to be indigenous to the soil, or perhaps it should be said to the inhabitants. Each tribe has its own characteristic aroma. Here, too, the curious fishing catamarans were novel and the fish unusual but highly edible.

Early Chinese Metallurgy

Through the wonderful rice fields of Rangoon to the silver mine in the highlands back of Mandalay. Here the old silver mine worked by the Chinese as early as the fourteenth century and not abandoned until 1868, probably because of water in the mines, for they were down to the 300 ft. level. The old Chinese metallurgical furnaces and cupels are still intact.

Another interesting paper was presented by W. A. Davis, of the American Brass Co., on "The Analysis of Metals by Spectroscopy."

At the conclusion of the technical program, election of officers of the section took place. H. C. Cooper was elected chairman, James Kendall, of Columbia University, vice chairman; Paul DeV. Manning, New York City, secretary.

Extensive Program for Peat Production in Michigan

The Peat Products Corporation, Eaton Rapids, Mich., recently organized with a capital of $100,000, is making ready for intensive operations on a 440-acre peat bog, near the city. A complete mechanical plant is in course of completion and it is purposed to produce at the rate of 100 tons of dried peat per day, commencing early in December. John H. Collins has been appointed secretary-treasurer and general manager at the plant.

Training and Aiding Workers in Industry

Personnel Association Discusses Timely Questions Affecting Selection and Welfare of Employees

Development of organized effort to study the human factor in commerce and industry and to apply the principles and practices arising therefrom to the realities of American industrial life mark a 3-day national forum of personnel experts held in Pittsburgh Nov. 8, 9 and 10 under the auspices of the National Personnel Association. Many of the country's principal manufacturing and mercantile enterprises, public service corporations, universities, engineering societies and civic bodies were represented as active participants in the movement, sponsored and directed from the association's headquarters in New York City.

Co-operation With Colleges

Among the notable reports presented to the convention was one dealing with "Co-operation With Engineering Colleges," prepared by a committee of which W. E. Wickenden, American Telephone & Telegraph Co., New York, is chairman, and of which F. L. Bishop, dean of engineering, University of Pittsburgh, and G. H. Pfeif, secretary of the educational committee of the General Electric Co., are members. Outlining ways and means by which assistance, through the association, can be rendered by industries to engineering colleges, the report says:

"The engineering colleges have a strong claim on the assistance of the industries in return for services rendered. The schools have made inestimable contributions to scientific knowledge from which the industries have profited without cost. Education has increased earning power and so has made possible the markets on which many industries depend for existence. The colleges have expended on each engineering graduate from $800 to $2,000 above all fees received. The industries profit by this training and would be compelled to provide costly substitutes for it if it were not available."

Immigration

Immigration was a principal topic of the convention. Magnus W. Alexander, managing director of the National Industrial Conference Board, discussed "Our Immigration Policy and Its Social and Economic Effects." "The Immigrant's Point of View" was the subject of Michael I. Pupin, immigrant, inventor, consulting engineer and professor of electromechanics in Columbia University. W. W. Kincaid, Niagara Falls, N. Y., delivered an address on "Nationwide Co-operation in Personnel Work," and E. K. Hall, vice-president of the American Telephone & Telegraph Co., on "Management's Responsibility for and Opportunities in the Personnel Job."

A committee, headed by E. K. Strong, Jr., director of the Bureau of Educational Research, Carnegie Institute of Technology, submitted a report saying that "psychological tests and rating scales are used today by a considerable number of corporations, and it is very evident that their use is being extended within those companies and to still other companies."

Vocational Training

Discussing the development of men for executive positions, a committee, headed by C. R. Dooley, manager of personnel and training, Standard Oil Co. of New Jersey, said that "companies having had training courses for several years invariably report that the effort and expense involved are justified by the results."

H. M. Jefferson, manager of the personnel department, Federal Reserve Bank, New York, presented a report on industrial motion pictures, finding that many non-theatrical films are distributed and used and that the demand for them is increasing.

Numbering of Steel

A conference to consider the desirability of providing a system of designating qualities or kinds of steels by code numbers has been called by the American Engineering Standards Committee at the request of the U. S. Bureau of Standards. The conference will be held in Room 704, Department of Commerce Building, Nineteenth St. and Pennsylvania Ave., Washington, D. C., at 10 a.m., Dec. 6.

This conference will attempt to determine the desirability of applying a uniform numbering system to forging steels, casting steels, structural steels, including plates, tool steels or other steels not so classified.

While the American Engineering Standards Committee has invited to this conference representatives of all technical and industrial associations known to be interested in the subject, any organization which feels that it should be represented in the conference, but has received no formal invitation, is urged to communicate with the American Engineering Standards Committee, 29 West 39th St., New York City.

Germany Imports Chilean Nitrate

On account of the great demand from farmers and to maintain trade relations with Chile, the importation of 200,000 tons of Chilean saltpeter has been sanctioned by the German Food Ministry, the right to import being given only to the Verein der Saltpeter Importeure at Hamburg, according to the *Frankfurter Zeitung*. In return the verein must sell 50 per cent to German farmers and 50 per cent to the fertilizer trade.

It is said that the German Government was influenced to permit imports of Chilean saltpeter by the fact that the restrictions on its import previously existing were leading to demands in Chile that imports of German goods into that country be similarly restricted.

Government Officials to Form Association

Branches in All Important Cities to Bring About Better Co-operation in Federal Business

Under the direction of the Bureau of the Budget a definite effort is being made for the first time to increase the efficiency of our great federal business machine by bringing together, in the larger cities of the country, all officials of the government in whatsoever department they are engaged. The work is under the personal supervision of General Herbert M. Lord, director of the Bureau of the Budget, and Colonel H. C. Smither, his chief co-ordinator. According to the plan federal business associations are to be organized in the larger cities for the purpose of bringing about a closer co-operation and co-ordination in carrying out the government's business.

Expect Economies

In these associations it is expected that economies will be realized from the interchange of transportation facilities, the consolidation of purchases, the storage of supplies and the co-ordination of many other activities to the common advantage of each of the different departments concerned. It is expected that the association will make possible the elimination of much duplication and a reduction in the expense of operation of the government.

The first Federal Business Association was formed in Chicago. At the organization meeting it was found that few federal officials stationed in that city were acquainted with officials representing departments and bureaus other than their own. Other associations have been formed in Detroit, Milwaukee and Boston and have already been in existence sufficiently long to prove their utility. It is now planned to carry the organization into Philadelphia, Baltimore and other large cities.

Before this plan was conceived there was little or no contact among federal officials stationed in the same city, but it is now apparent that economies and other advantages of the greatest importance will be brought about.

Rise of German Potash Price Charged to Production Cost

Inland potash prices in Germany increased 250 per cent between Oct. 1 and Nov. 15, according to cable advices reaching Washington. The increase is chargeable largely to increases in freight rates, in coal prices and in miners' wages. Despite the increase in prices, it is estimated that the Germans will sell more potash in 1922 than in any pre-war year, deprived as they are of the Alsatian mines.

The same cable states that the German chemical industries had a good month in October with the sole exception of the dye producers, who report further decreases in the demand.

Dickson Will Be Dye Expert of State Department

Move May Presage Organization of Government Distributing Agency for Reparation Dyes

Announcement that the State Department has temporarily employed F. S. Dickson as an expert on dyes has been made. It is believed that this move indicates plans of the government to undertake the distribution of the reparation dyes.

Mr. Dickson, who directed the dye license plan under the emergency tariff act, will give the department the benefit of his expert knowledge of the dye situation and will advise as to the best method for the handling of the German dyes. As Mr. Dickson had to pass upon the applications of importers for the entry of foreign dyes and had to consult the American manufacturers to learn whether or not these dyes were satisfactorily produced in this country, the State Department feels that he is well qualified for the position.

The Secretary of State has made known that a note from the Allies has been received, notifying the United States that they will not oppose the receipt of German reparation dyes without cost, to be applied against the costs of the army of occupation.

Agricultural Chemists Hold Sessions in Washington

Chemists and professional men generally must be particularly careful to guard against any influencing of their opinions by the fee which they are receiving or by the desires of their employer. Senator Ladd, of North Dakota, himself a chemist, sounded the foregoing warning in the course of an address before the thirty-eighth annual convention of the Association of Official Agricultural Chemists, which was held in Washington last week. Senator Ladd fears that there is an increasing tendency to yield to the temptation to bring forth the opinions desired by the employer. He made specific references to expert witnesses. It is unethical, he said, for a witness to bring out only such part of the facts as will help the side which is paying his fee. It is the belief that it undermines the reputation of the processions, as well as that of the individual, when it is known that the expert witness would be able to make a strong showing for either side that employed him.

Dr. Harvey W. Wiley told the association that despite all of the research and effort it must be admitted that there is no known cure for cancer. He regards the possibilities of radium as promising, but it may be difficult to confine its effects to diseased tissue.

Officers were elected as follows: A. J. Patten, Michigan Agricultural College, president; R. E. Doolittle, of the Chicago office of the Bureau of Chemistry, vice-president, and W. W. Skinner, assistant chief, Bureau of Chemistry, secretary and treasurer.

Attempt to Stop Long Working Hours for Government Employees

The 12-hour day and 7-day week in government service and what is to be done to stop it was one of the questions under consideration by the executive council of the National Federation of Federal Employees, in session last week in Washington. In countless instances throughout the country the 12-hour day and 7-day week prevail in government employ. Specific instances of this abuse are cited by Vice-President Lee R. Whitney of Milwaukee, Wis., as occurring in his part of the country among firemen in the government buildings and lock masters on the Fox River in Wisconsin. The lock masters, according to Mr. Whitney, are on duty really day and night and often as long as 16 hours.

Engineers in most of the federal buildings in Washington work 7 days a week and in the Custodian Service in Baltimore, according to Vice-President Charles L. Wiegand of that city, the employees are on duty 7 days a week without extra pay and with no compensatory time. Similar conditions prevail in the Custodian Service almost everywhere in the country. Immigration and customs officers on the Canadian border are likewise working the 12-hour day and 7-day week.

These matters will be taken up by the council with the various departments or with Congress, as the situation may require.

Liquid Carbon Dioxide Research Fellowship Established at Mellon Institute

The liquid carbonic division of the Compressed Gas Manufacturers' Association announces the establishment of an industrial fellowship in the Mellon Institute of Industrial Research of the University of Pittsburgh, for the purpose of classifying, studying and developing the uses for liquid carbon dioxide. The founding of this fellowship is in accord with the desire of the members of the association to cooperate with users and prospective users of liquid carbon dioxide, with the object of developing efficient means of applying the gas and of obtaining fundamental data bearing on its use in various industries.

In addition to conducting research work, the fellowship will be made a clearing house of information regarding various uses of liquid carbon dioxide, and data will be kept on file for the accommodation of prospective users of this product.

The present incumbent of the industrial fellowship is Charles L. Jones, who will be glad to correspond with anyone interested in the use of liquid carbon dioxide in industry.

Bayer Co. Complaint Dismissed

The Federal Trade Commission announces the dismissal of its complaint against the Bayer Co., Inc., of New York City, manufacturer and distributor of Aspirin tablets.

Power Show Promises to Be Interesting

Exhibits Planned Will Touch Every Phase of Power Development and Application

The great interest aroused forecasts a phenomenal success for the first National Exposition of Power and Mechanical Engineering, which will open Thursday, Dec. 7, at the Grand Central Palace and extend through Dec. 13, with the exception of the intervening Sunday. Practically all of the exhibition space has been leased and requests for approximately two hundred thousand tickets have been received by the management.

The exposition covers the field of power and mechanical engineering from the moment the coal is taken from the ground until the power is turned into work in the final machine. Not only will there be representatives of prime movers and steam-generating devices but also exhibits of manufacturers who have devoted their efforts to the solution of the troublesome problems involved in burning fuel and making and using power.

Educational Aspects

Engineering university students are to be made especially welcome at the exposition. Special facilities have been offered for organized college classes to visit the show in a body and rooms will be set aside for special lectures about any of the material that is displayed at the show. In this manner the students will be given an intimate contact with the practical application of the various types of engineering apparatus exhibited. The exhibitors are planning to have properly equipped representatives who may explain fully the technical reasons for any apparatus or detail.

Interesting Exhibits

Among the exhibits of special interest will be that of Gillis & Geoghegan, who will show four models of telescopic hoists with complete equipment for removing ashes. Two electric models will be in operation.

The Keasbey & Mattison Co. will operate a steam unit with sections covered by various forms of insulating material. By means of thermometer readings and charts the actual savings in B.t.u. will be clearly demonstrated and the results will be worked out in various ways to show the savings in tons of coal and dollars and cents by the use of the proper kind of insulation.

The display of the Lunkenheimer Co. will feature two motor-controlled valves equipped with the Deane system of control. One of the valves is a 12-in. cast steel Monel mounted gate valve which made such a notable showing at the Essex tests, in which by means of this control the flow of steam from the open valve was stopped. A remarkably complete line of cast steel Monel mounted valves for operating conditions of 350 lb. W.S.P. and 800 deg. F. total temperature will also be presented.

Caetani to Be Guest of Honor at Engineers' Banquet

A reception and banquet at which Prince Gelasio Caetani, the new Ambassador from Italy to the United States, will be the guest of honor, is being planned by the Federated American Engineering Societies. L. W. Wallace, executive secretary of organization, has written Ambassador Caetani telling him of the desire of the engineers in this country to pay him this mark of respect. No information has been received as yet at the Italian Embassy as to the time of the new Ambassador's arrival. It is believed, however, that he will be in this country by the first of the year, in which case Mr. Wallace hopes to arrange to have Prince Caetani as the guest of honor at the annual banquet of American Engineering Council. If that proves to be practicable, arrangements will be made so that all engineers who desire may attend.

Personal

Dr. JEROME ALEXANDER has established himself as a consulting chemist in the Chemists' Building, 50 East 41st St., New York City.

Dr. CLARENCE W. BALKE, of the Pfansteel Products Co., of North Chicago, Ill., is to be chairman of a symposium on "Rare Metals in Industry" to be presented at the New Haven meeting of the American Chemical Society.

W. M. CORSE presented, to the Chemical Society of Washington, an address illustrated by motion pictures, entitled "The Mining and Smelting of Nickel Ores," on Nov. 9.

PAUL CROLL, formerly research chemist of the N. J. Zinc Co., has been engaged by the Patton-Pitcairn division of the Pittsburgh Plate Glass Co., Milwaukee, Wis.

WILLIAM P. CUTTER has resigned from the position of librarian of the research library of the National Aniline & Chemical Co. at Buffalo, to accept a position with Arthur D. Little, Inc., of Cambridge, Mass.

D. D. DROBYNS has been elected president of the Pennsylvania Oil & Fuel Co., Pittsburgh, Pa.

PETER FEIBERGER, a chemist who specializes in color work, has been appointed head of the dye investigation laboratory of the Customs Division of the Treasury Department in New York, and will be in charge of the tests of comparability which are necessary under the new tariff act in the coal-tar products paragraphs. He will also assist in the standardization work under the same paragraphs. Mr. Feiberger for the last several years has been retired from active work. He will appoint three assistant chemists to help in the work in New York.

HARRY GLAIR has recently been appointed assistant superintendent of the Whiting plant of the Standard Oil Co. of Indiana. Previously he had charge of the paraffin department of that company.

R. T. GOODWIN has joined the research staff of the Standard Oil Co. of N. J., specializing on shale oil.

Dr. ELLWOOD HENDRICK, consulting editor of *Chem. & Met.*, spoke at the open forum of the Peoples' Institute at Cooper Union, on Sunday evening, the 12th inst. His subject was "A Vision of Science." On Nov. 22 he will address the Wilmington, Del., section of the American Chemical Society on "The Language of Chemistry" and on Dec. 14 he will speak before the Chemistry Club of Princeton, N. J., on the same subject.

L. F. HOYT, chemical expert of the research department of the Larkin Co., Buffalo, N. Y., manufacturer of soaps, etc., gave an interesting address, Nov. 6, before the chemical group of the local Chamber of Commerce. He spoke, in part, on the importance of the chemical laboratory in modern plants.

SIDNEY HULL, at one time a research chemist in the organization of the Cincinnati Chemical Works, Inc., and later employed by the Newport Chemical Works, is now in the Chicago laboratory of the Western Electric Co.

CLIFTON N. JACOBS, formerly chemistry instructor at the Massachusetts Institute of Technology, is now chief chemist of the Diamond State Fibre Co., Bridgeport, Pa.

JOHN R. KEUBLER, editor of *The Hexagon* of Alpha Chi Sigma, the professional chemical fraternity, is in charge of the chemistry department at the Shortridge Technical School of Indianapolis.

Dr. OTTO KRESS has resigned his position as technical director for the Consolidated Water Power & Paper Co., Wisconsin Rapids, Wis., to accept a similar position with the Thilmany Pulp & Power Co., Kaukauna, Wis.

L. G. KRUG, formerly with A. Daigger & Co., of Chicago, was recently appointed assistant sales manager for the Chicago Rawhide Co.

THOMAS LECLEAR, formerly with the Uniform Color & Chemical Co., of Perth Amboy, N. J., is now associated with H. B. Baldwin, chemist to the Newark Board of Health.

CURTIS C. MEIGS, formerly president of the consulting chemical engineering firm of Meigs, Bassett & Slaughter, Inc., with offices at 1304 Finance Bldg., Philadelphia, has sold his interest to Messrs. Bassett and Slaughter, who will continue to carry on the business at same address under the name of Bassett & Slaughter, Inc. Mr. Meigs has taken offices at 709-710 Stephen Girard Bldg., and has associated himself with Hugo Schlatter, formerly with the Hercules Powder Co., and W. B. Goentner, who was assistant chief mechanical engineer for the old firm. These men will carry on the work of consulting chemical engineering at this address.

Dr. R. B. MOORE, chief chemist of the Bureau of Mines, discussed radium in an address before the students of Smith College, on Nov. 10. On the following day he addressed the Connecticut Valley section of the American Chemical Society at Westfield. His remarks on that occasion were confined to helium.

Dr. C. R. MOULTON, director of the department of agricultural chemistry of the University of Missouri, has been appointed director of the bureau of nutrition of the Institute of the American Meat Packers' department of education and research, which position he has accepted, effective Jan. 1. Dr. Moulton was graduated from the University of Illinois in 1907. He received his master's degree from the University of Missouri in 1909 and took his doctor's degree at the same institution in 1911. From 1917 to 1918 he was an assistant in animal nutrition to the late H. P. Armsby at the Institution of Animal Nutrition, Pennsylvania State College.

Dr. W. H. RODEBUSH, professor of physical chemistry at the University of Illinois, addressed the Illinois section of the American Chemical Society on Nov. 21. His subject was "The Production of Helium for Military Purposes."

JOHN WALDO, who taught chemistry last year at Morningside College, is now an instructor in inorganic chemistry at Purdue University.

GEORGE B. WATERHOUSE has been appointed professor of metallurgy at the Massachusetts Institute of Technology, Cambridge, Mass.

W. R. WHITNEY, director of the research laboratory of the General Electric Co., Schenectady, N. Y., expected to sail for Europe on Nov. 21.

HENRY WIGGLESWORTH, formerly director of development of the General Chemical Co., has returned to the United States for a short season, after an absence of a year. Mr. Wigglesworth has made a number of valuable connections in chemical industry abroad, and will return shortly to Great Britain and the Continent on pressing business. He is stopping with his family for the present at Hotel Vanderbilt, New York.

W. W. WITMER, formerly a chemical engineer with the du Pont company and later connected with the Hoskins Process Development Co., of Chicago, has recently been appointed superintendent of the plant of the Special Chemicals Co., at Highland Park, Ill.

The Paint Manufacturers' Association of the United States has elected the following officers: President, Charles R. Cook of the Cook Paint & Varnish Co., Kansas City; first vice-president, Samuel R. Matlock, of Philadelphia; second vice-president, Samuel Rosenthal, of Chicago, and secretary-treasurer, George B. Heckel, of Philadelphia. The following directors were also elected: Dr. D. A. Kohr, of Dayton; L. T. Minehart, of Denver; H. J. Kuhn, of Houston; Andrew Butler, of Buffalo, and S. B. Woodbridge, of Philadelphia.

Market Conditions

Successful Business Promotion

National Paint, Oil and Varnish Association Well on Its Way Toward Doubling the Industry

A year ago when the general business depression was admittedly at its worst the national trade association of the paint and varnish industry outlined a most ambitious program of business promotion. Two campaign slogans were adopted: "Make 1922 the greatest paint and varnish year" and "Double the industry by 1926." Already there is abundant evidence that in spite of the unfavorable situation during the early months of the current year, the paint and varnish manufacturers will have attained the goal set for 1922. Furthermore, a great step has been taken toward the successful fulfillment of the 5-year program.

President Ernest T. Trigg, in his address last week before the annual convention of the National Paint, Oil and Varnish Association, predicted that 1922 will exceed the banner year of 1920 by 11.6 per cent. This is an increase of 31.6 per cent over last year's volume of production. Thus 1922 must be conceded "the greatest paint and varnish year" in the history of the industry. In one year the industry has attained almost a third of the 100 per cent increase set for 1926.

The "Save the Surface" and "Clean Up and Paint Up" campaigns have had a great deal to do with this remarkable showing, but back of these ideas is a story of intensive work, improved selling and advertising methods and constructive co-operation on the part of manufacturers and dealers.

More Thought to Fundamental Business Conditions

A study of the causes of business failures shows that the success or failure of individual enterprises depends largely on three sorts of factors: (1) Those within the particular plant or factory. (2) Those within the trade or industry. (3) Those involved in the general business situation. Or, as is stated by the Harvard Economic Service in one of its recent letters, "An enterprise may fail because its plant is antiquated or its technical methods are wasteful. Or it may fail because the trade in which it is engaged is decadent or temporarily overdone. Or it may fail because it is unable to survive the throes of widespread business."

Many of the industrial embarassments and bankruptcies of 1920 were largely due to the drastic monetary deflation, the general credit contraction and receding prices. Thus it was factors outside of their own organization and beyond their immediate control that were most responsible for their troubles. Out of this has come a realization of the value of a better understanding of general business conditions. The broader use of statistics and the more general study of the fundamentals of business are some of the progressive developments resulting from the lessons taught us by the business depression.

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

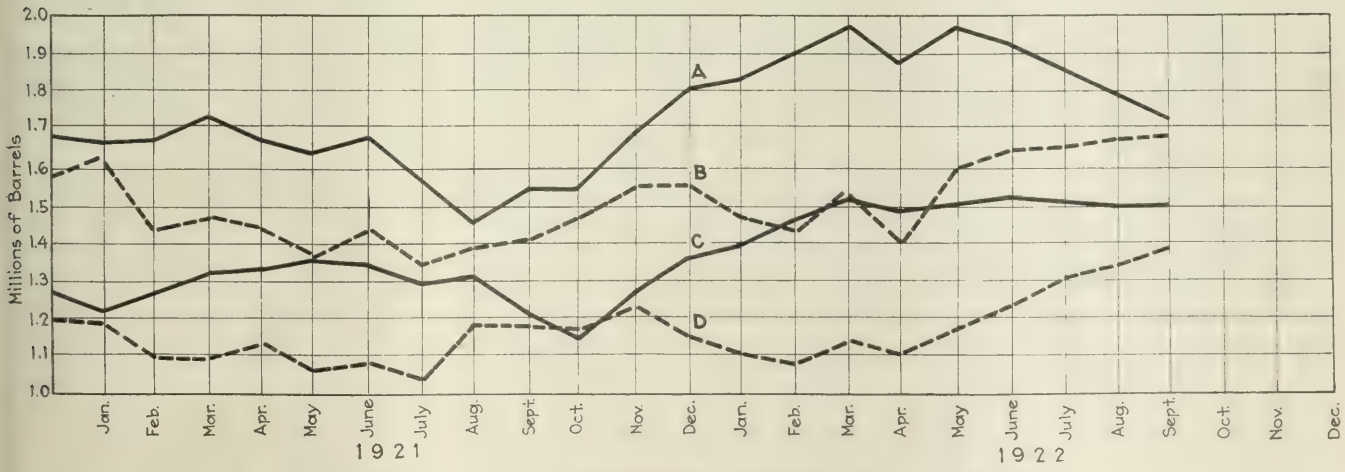
This week	162.83
Last week	158.70
November, 1921	146.82
November, 1920	240
April, 1918 (high)	286
April, 1921 (low)	140

The continued advance in this index shows an encouraging condition in the chemical market. Higher prices for methanol, formaldehyde, caustic potash and cottonseed oil more than offset the weaker market for ammonium sulphate, aniline and linseed oil.

Crude Petroleum Production for September, 1922

The outstanding trends in the statistics of crude petroleum for September, 1922, are that imports continued to decrease and consumption to increase. Since production was almost stationary, this resulted in the smallest net addition to stocks. 1,363,000 bbl., that has been recorded since October, 1921.

The daily average production, which has remained close to 1,500,000 bbl. for the last 7 months, amounted to 1,508,200 bbl. in September, according to the reports made to the U. S. Geological Survey. A gain of 24,616 bbl. in California was partially offset by losses in other states, including 7,711 bbl. in Texas and 6,868 bbl. in Oklahoma. The decrease in the imports of light crude oil from Mexico from 6,217,000 bbl. in July to 2,683,000 bbl. in September emphasizes the declining production in the Southern fields.



STATISTICS OF CRUDE PETROLEUM, JANUARY, 1921, TO SEPTEMBER, 1922
Daily Averages for —

(A) Domestic production of petroleum plus imports of "mineral crude oil."
(B) Consumption plus exports of domestic and imported petroleum.
(C) Domestic production (petroleum transported from producing properties).
(D) Consumption plus exports of domestic petroleum.

The New York Market

NEW YORK, Nov. 20, 1922.

Firmer prices throughout the list of chemicals were reported and the general demand for some of the basic chemicals was regarded as quite satisfactory. Prices are on a steady basis, with the tendency toward higher levels. Foreign competition has been less noticeable during the interval and spot stocks were greatly diminished among second-hand merchants. The feature of the week's activities appeared in the market for alcohol products. Manufacturers announced another advance on methanol and the entire list of solvents suddenly became the center of unusual activity. Arsenic still continued on its upward trend and was regarded as one of the strongest items of the list. Consumers have shown a desire to purchase at the high levels and spot supplies have become exceedingly limited. Domestic dealers in camphor announced an advance of 3c. per lb., bringing their price to 93c. per lb. The export market on caustic soda and soda ash revealed little change and transactions were mostly for small lots. Yellow prussiate of potash showed a very strong market and dealers advanced prices 1c. per lb. during the week. Bleaching powder, prussiate of soda, permanganate of potash, barium carbonate, bichromates and sodium compounds continued along moderate lines, with very little selling pressure noticeable.

GENERAL AND SPECIAL CHEMICALS

Acetate of Soda—Importers have been in direct competition with domestic makers and the market recorded a slight decline. Quotations were reported around 7¼c. per lb. for the imported and domestic grades.

Acetone—Carload quantities were held around 18½@19c. per lb. Most trading, however, was for small lots and sellers were asking 22@23c. per lb. Spot stocks are rather limited.

Alcohol—Makers of methanol have announced another advance of 10c. per gal. The 95 per cent material is being quoted at $1 per gal. in drums and $1.07 in barrels. The 97 per cent is held at $1.03 per gal. in drums and $1.10 in barrels. Ethyl alcohol is quotably unchanged at $4.75@$4.90 per gal.

Arsenic—Transactions have been recorded at 12¼@12½c. per lb. on spot. The inside price was difficult to ascertain during the latter part of the week and most holders were asking 12½c. Consumers have come into the market in larger numbers and dealers predict a 15c. per lb. market in near future.

Barium Chloride—The tone of this market has been somewhat unsteady and trading was restricted to small lots. Prices on spot ranged from $95@$105 per ton, with shipments held at $95.

Chlorate of Soda—The spot market is quite strong at 6¾c. per lb. Supplies are very scarce and producers report a well sold-up condition at the works.

Cyanide of Soda—The general condition is somewhat weak and sales were reported for small lots at 19½c. per lb. The domestic price is still holding at 25c. per lb., f.o.b. works.

Formaldehyde—The recent advance in methanol placed this product in a much stronger position. Dealers were not inclined to quote round lots and were asking as high as 14¼c. per lb. for 10-bbl. lots. Factors reported a sold-up condition for the remainder of the year. The tendency is toward much higher levels.

Prussiate of Potash — Several transactions have been recorded up to 39c. per lb. Supplies remained very light and dealers showed little disposition to offer material at the market figure. The red variety was in good demand at 90c. per pound.

Prussiate of Soda—The spot market is easier and prices are fractionally lower. The demand is only moderate and small-lot sales were recorded at 21¼c. per lb., with the range around 21¼@21½c. per pound.

COAL-TAR PRODUCTS

The feature of the coal-tar products market was the outstanding strength in all crude products. Producers report a sold-up condition at the works and a very strong demand from consumers. One of the largest factors has been consistently turning down orders for cresylic acid, phenol and benzene over the remainder of the year and as far ahead as February, 1923. Raw materials have been exceedingly difficult to purchase and deliveries on old contracts have been delayed in several instances. Imported material is being brought into the market very slowly and factors are not fearing any selling pressure, in view of the present tariff rates. Phenol continues quite scarce on spot and demand is exceedingly strong. Prices have been again advanced in the resale market, although makers have announced no new price.

Aniline Oil—Producers report the market fairly active, with business along moderate lines. The lowest price heard is around 16c. per lb. with the general range at 16@17c. per pound.

Beta Naphthol—The technical variety is moving in fair volume and the general tone is firm at 24@25c. per lb. Sublimed material is held at 55@60c. per pound.

Dimethylaniline—There has been a much stronger demand, due to the higher producing costs. The recent alcohol advance has added new interest and prices were advanced to 36@38c. per pound.

Ortho-Nitrophenol—Higher costs of raw material have caused an advance in this product. Spot offerings are limited and sellers have advanced prices to 85@90c. per pound.

Cresylic Acid—Domestic factors are still quoting 60c. per gal. for the 97 per cent and 55c. per gal. for 95 per cent material, but announce a sold-up condition for the remainder of the year and as far ahead as February, 1923. Imported 97 per cent goods on spot, in drums, is being quoted as high as 90c. per gal. and is finding a ready market.

Phenol—Producers continue to quote 22c. per lb. on contract, but report a completely sold-up condition at the works. Spot goods are very scarce and dealers are quoting up to 37c. per lb. for limited quantities. All indications point to a much higher market in the very near future.

Chemical Exports Continue to Gain

But Nine Months Total for 1922 Is Still Slightly Below Same Period of 1921

Although the exports of chemicals and allied products for the first nine months of 1922 still show a decrease over the corresponding period of 1921, the proportion of decrease continues to be lessened until the decrease is now only one-half of one per cent. The figures for 1922, according to a recent report of the Chemical Division of the Department of Commerce, are $79,741,439, and for 1921, $80,193,257.

The increases and decreases remain in about the same general classes—namely, fertilizers, explosives, and naval stores, gums and resins, for increases, and in coal-tar chemicals, and pigments, paints and varnishes for decreases.

Of the heavy chemicals exported, the largest increases are, as before, in caustic soda and borax, the per cent of increases being 330 and 210, respectively. However, some of the other sodium compounds did not fare as well, the exports of soda ash diminishing from $646,291 in 1921 to $502,518 in 1922, and of sal soda from $154,191 to $134,908. The following table shows some of the more important items.

Gains for the period under discussion over the corresponding period of 1921 occurred in the exports of explosives (55 per cent), perfumery and toilet waters (30 per cent), and fertilizers (7 per cent), exports of explosives increased from $1,515,205 (6,343,754 lb.) to $2,350,539 (12,979,433 lb.), and of perfumery and toilet waters from $3,515,070 to $4,551,619. Of the amounts of fertilizers exported for the 9 months of 1922, shipments of ammonium sulphate continued to increase from $4,119,858 in 1921 to $7,075,225 in 1922, and superphosphates from $94,030 to $317,087, while phosphate rock decreased from $5,803,811 to $4,442,948.

	Jan.–Sept., 1921		Jan.–Sept., 1922

The St. Louis Market

ST. LOUIS, MO., Nov. 16, 1922.

Firmness is the important feature of the chemical market today, although very few price changes have taken place in the leading industrial chemicals since our last report. The volume of business transacted to date has been very satisfactory. Although a natural decrease in buying is expected at this period of the year for inventory purposes, it is not believed that this reduction will be above the normal this year, and it is expected that with the beginning of the year there will be a noticeable increase in business. Furthermore, it is not expected that the natural decrease this year will have any tendency to weaken prices, but that a steady tone will be maintained over the remainder of this year. Transportation facilities are still abnormal and not much improvement is expected for some time on account of the poor equipment with which the carriers are now operating.

THE ALKALI MARKET

As yet there is nothing startling or in fact nothing new to report in the alkali market. *Caustic soda* is moving only in a routine way and still maintains the prevailing price of the last 30 or 60 days. In 5-drum lots the solid is being quoted at $3.80 per 100 lb., and the flake at $4.25. *Soda ash* is slightly weaker. No price decline in general has been noted, though in one or two instances quotations have been made 5c. under prevailing schedule, which is as follows: in quantities of 5 bags or more for the 58 per cent light, $2.20 per 100 lb., while the usual differential of 20c. for barrels over bags prevails. *Bicarbonate of soda* has for some time maintained a steady price of $2.40, and while no large orders are passing, the price is holding firm. *Sal soda* is entering a slow season, but prices have not declined any since our last report and sales are light.

GENERAL AND SPECIAL CHEMICALS

Sales of *citric acid* are very small, and of a routine nature. The firmness in the *oxalic acid* market was broken about 10 days ago with the arrival of a large lot of imported material. Apparently, however, this has now been absorbed and the market has again assumed a firmer tone. Domestic producers now quote 17c. per lb. in barrels and 17½c. per lb. in kegs, f.o.b. St. Louis. Trading in *tartaric acid* is normal and no sales of consequence have been reported. *Aqua ammonia* 26 deg. has shown no unusual activity in the past few weeks and prices remain unchanged. The *white arsenic* market is still soaring, and the best that can be done today is 12½c. per lb. in carload lots, f.o.b. St. Louis. The supply is very scarce and spot stocks are practically out of the question, and it appears that this shortage is going to last for some time, as some of the large producers report that their entire output for next year has been taken up. Further advances might be seen shortly. *Cream of tartar* remains very dull, with the demand practically nil. *Glycerine* is moving in good volume and prices remain firm at 18½c. in drums. The market is entirely in the producers' hands. Only small lots of *phenol* are offered and the aggregate of spot stocks is very small, and some imported material is in evidence. *Bichromates of potash and soda* are in fairly good demand, and contracts for next year's requirements are being offered at slightly lower prices than the spot market.

VEGETABLE OILS AND NAVAL STORES

Castor oil is still holding at its previous level of 13½c. in drums and moving in good volume. *Turpentine* continues to hang around $1.70 per gal., being quoted today at $1.68, 4c. lower than when we last reported. However, it has been above as well as below that price during the interval. *Linseed oil* has scarcely changed during the last 2 weeks and continues around $1.

The Iron and Steel Market

PITTSBURGH, Nov. 17, 1922.

Steel production continues at fully as heavy a rate as in October, when ingots were being produced at 40,000,000 tons a year, representing an operation of the steel industry as a whole at slightly above 75 per cent of capacity.

Shipping of steel is as difficult as ever, but in general shipments total as much as production. There has been a further accumulation of sheets. Even in October the independent sheet mills that make monthly reports showed 20,000 tons more produced than shipped, although at the beginning of October there was 102,198 tons produced on order and awaiting shipment.

FINISHED STEEL MARKETS QUIET

The finished steel markets are all very quiet, and some lines are practically stagnant. The market turnover is easily the lightest of any time this year. The condition does not reflect any decrease in actual consumption, being rather the result of the heavy deliveries on old orders now being made.

Finished steel prices are steady at basis rates—i.e., the rates that have obtained lately on late deliveries. The rather heavy delivery premiums that were ruling a couple of months ago on bars, shapes, plates and sheets have disappeared, that being the principal change in the market. It is possible now to get quite early deliveries on new orders, except in nails and the smaller sizes of merchant steel pipe. In these, particularly in pipe, the mills fall quite short of meeting customers' desires. This exceptional condition is of course a reflection of the remarkable boom in garage and dwelling house construction.

Basis prices referred to above, which have lately been the regular prices of the Steel Corporation, are: Bars, shapes and plates, 2c.; merchant steel pipe, 66 per cent basing discount; hoops, ordinary specifications, including cooperage stock, 2.90c.; plain wire, 2.45c.; wire nails, $2.70; tin plate, $4.75; black sheets, 3.35c.

While black sheets have in the past week completed their decline to the Steel Corporation price, blue annealed sheets are frequently bringing above 2.50c. and galvanized above 4.35c., while automobile sheets seem to command 5c. in all cases, though the corporation's price, at which it has been sold out for some time past, is 4.70c. The corporation's prices on sheets for first quarter and tin plate for first half have appeared on the verge of being announced for 2 or 3 weeks past.

NO INDICATIONS OF PRICE CUTTING

From the viewpoint of last September, so large an increase in steel shipments as has occurred would probably have been expected to produce either price cutting or curtailment in operation at some mills through scarcity of orders, but there has been no such development as yet. Apparently there are few independent mills and perhaps no large independent mills needing additional business to carry their present operating rate through the year. There is of course the contingency of some customers instructing mills to curtail the rate of shipment.

Prospects are that the Steel Corporation will show a decrease in unfilled obligations for the present month, in view of the heavy shipments, the quiet market at present and the fact that the September increase of 741,502 tons and the October increase of 210,680 tons were due chiefly to heavy contracting for rails and track material, business that is now concluded. The unfilled obligations of 6,902,287 tons at the end of October is equivalent to nearly 6 months of production at a 75 per cent rate, the obligations being quite unequally divided, however, among the different products.

PIG IRON AND COKE

The pig iron markets in all districts continue stagnant and weak, with prices declining slightly at frequent intervals. Birmingham iron is down to $23, a drop of $2 in the week, and many of the Northern markets have declined $1. Valley basic has sold at $28 furnace, $1 under the nominal quotation of a week ago, but furnaces elsewhere are making prices that will force further declines if the valleys are to retain their trade. Valley foundry is down 50c. to $28.50, bessemer remaining at a nominal quotation of $32.

Connellsville furnace coke has lost 25c. this week, being now at $6.75@$7.25. The further decline brings little if any comfort to merchant furnaces, because these furnaces very largely covered to the end of the year on the decline of a month ago from $12 to $8, while the further decline in coke exerts an adverse sentimental effect on pig iron prices. Connellsville foundry coke remains at $8@$9.

General Chemicals

Current Wholesale Prices in New York Market

		Carlots F.o.b. N. Y.	Less Carlots F.o.b. N. Y.

Chloroform	lb.		.35 – .38
Cobalt oxide	lb.		2.10 – 2.40
Copperas	ton	27.00 – 28.00	29.00 – 30.00
Copper carbonate, green precipitate	lb.	21 – 21½	.22 – .22½
Copper cyanide	lb.		.50 – .55
Copper sulphate, crystals	100 lb.	5.75 – 6.00	6.10 – 6.50
Cream of tartar	lb.		.25 – .26
Epsom salt (see magnesium sulphate)			
Ether, U. S. P., 100 drums	lb.		.14 .15
Ethyl acetate com., 85%	gal.		.72 .75
Ethyl acetate, pure (acetic ether, 98% or 100%)	gal.		.90 .95
Formaldehyde, 40 per cent	lb.	.14½ – .14¾	.14 – .15
Fullers earth, f.o.b. mines	net ton	16.00 – 17.00	
Fullers earth—imported powdered	net ton	30.00 – 32.00	
Fusel oil, refined	gal.		3.00 – 3.50
Fusel oil, crude	gal.		2.00 2.25
Glauber's salt (see sodium sulphate)			
Glycerine, c.p., drums extra	lb.		.18 .18¼
Iodine, resublimed	lb.		4.40 – 4.50
Iron oxide, red	lb.		.12 .18
Lead acetate, white crystals	lb.		.12 12½
Lead arsenate, powd.	lb.	.13 – .13½	13 .14½
Lead nitrate	lb.		15 .20
Litharge	lb.	.07½ – .08	.08½ .09
Magnesium carbonate, technical	lb.	.06 – .06½	06 .07¼
Magnesium sulphate, U. S. P.	100 lb.	2.50 – 2.65	2.70 – 3.50
Magnesium sulphate, technical	100 lb.		1.00 – 1.80
Methanol, 95%	gal.		1.00 – 1.07
Methanol, 97%	gal.		$1.03 –$1.10
Nickel salt, double	lb.		.11 – .11½
Nickel salt, single	lb.		.12 – .12½
Phogene (see carbonyl chloride)			
Phosphorus, red	lb.		.40 – .45
Phosphorus, yellow	lb.		.30 – .35½
Potassium bichromate	lb.	$0.10 – .10¾	.10½ – .11
Potassium bromide, granular	lb.		.17 – .23
Potassium carbonate, U. S. P.	lb.	.12 – .12½	.13 – .16
Potassium carbonate, 80–85%	lb.	.06 – .06½	.06½ – .06¾
Potassium chlorate, powdered and crystals	lb.	.07½ – .08	.08¼ – .09
Potassium cyanide	lb		.55 – .57
Potassium hydroxide (caustic potash)	100 lb.	6.50 – 6.60	6.65 – 7.00
Potassium iodide	lb.		3.45 – 3.55
Potassium nitrate	lb.	.06½ – .06¾	.07 – .08
Potassium permanganate	lb.	.16 – .16½	.16½ – .17
Potassium prussiate, red	lb.		.90 – .95
Potassium prussiate, yellow	lb.	39 – .39½	.39½ – .40
Rochelle salts (see sodium potas. tartrate)			
Salammoniac, white, granular	lb.	.06½ – .06¾	.07 – .07½
Salammoniac, gray, granular	lb.	.08 – .08½	.08½ – .08¾
Salsoda	100 lb.	1.20 – 1.40	1.45 – 1.60
Salt cake (bulk)	ton	25.00 –27.00	
Soda ash, light, 58 per cent flat, bags, contract	100 lb.	1.60 – 1.67	2.00 – 2.25
Soda ash, light, 58 per cent flat, bags, resale	100 lb.	1.75 – 1.80	1.85 – 2.35
Soda ash, dense, in bags, resale	100 lb.	1.85 – 1.90	1.95 – 2.40
Sodium acetate	lb.	.07½ – .07¾	.08 – .08¼
Sodium bicarbonate	100 lb.	1.75 – 1.85	1.90 – 2.30
Sodium bichromate	lb.	.07½ – .07¾	.08 – .08¼
Sodium bisulphite (nitre cake)	ton	4.50 – 4.60	4.65 – 5.50
Sodium bisulphite powdered, U.S.P.	lb.	.04¼ – .04½	.04¾ – .05¼
Sodium chlorate	lb.	.06½ – .07	.07¼ – .07½
Sodium chloride	long ton	12.00 –13.00	
Sodium cyanide	lb.	.19½ – .21	.21½ – .25
Sodium fluoride	lb.	.09¾ – .10	.10¼ – .10½
Sodium hydroxide (caustic soda) solid, 76 per cent flat, drums, contract	100 lb.	3.35 – 3.40	3.75 – 4.00
Sodium hydroxide (caustic soda) solid, 76% flat, drums, resale	100 lb.	3.60 – 3.65	3.70 – 4.00
Sodium hydroxide (caustic soda), ground and flake, contracts	100 lb.	3.80 – 3.90	4.25 – 4.40
Sodium hydroxide (caustic soda) ground and flake, resale	100 lb.	4.00 – 4.15	4.40 – 4.60
Sodium hyposulphite	lb.	.02½ – .02¾	.03 – .03½
Sodium nitrite	lb.	.09 – .09¼	.09½ – .10
Sodium peroxide, powdered	lb.	.28 – .30	.31 – .35
Sodium phosphate, dibasic	lb.	.03½ – .04	.04¾ – .04½
Sodium potassium tartrate (Rochelle salts)	lb.		.18 – .21
Sodium prussiate, yellow	lb.	.21¼ – .21½	.21¾ – .22
Sodium silicate, (40 deg. in drums)	100 lb.	.80 – 1.00	1.05 – 1.25
Sodium silicate, (60 deg. in drums)	100 lb.	2.25 – 2.40	2.45 – 2.75
Sodium sulphate, crystals (glaubers salt)	100 lbs.	.85 – .95	1.00 – 1.40
Sodium sulphide, fused, 60-62 per cent (conc.)	lb.	.04 – .04½	.04¼ – .05
Sodium sulphite, crystals	lb.	.03½ – .03⅝	.03¾ – .04¼
Strontium nitrate, powdered	lb.	.09½ – .10	.10¼ – .12
Sulphur chloride, yellow	lb.	.04½ – .05	.05¼ – .06
Sulphur, crude	ton	18.00 –20.00	
Sulphur dioxide, liquid, cylinders extra	lb.	.08 – .08½	.09 – .10
Sulphur (sublimed), flour	100 lb.		2.25 – 3.10
Sulphur, roll (brimstone)	100 lb.	2.00 – 2.15	2.20 – 2.70
Talc—imported	ton	30.00 –40.00	
Talc—domestic powdered	ton	18.00 –25.00	
Tin bichloride	lb.	.10 – .10¼	.10½ – .10¾
Tin oxide	lb.		.43 – .45
Zinc carbonate	lb.	.14 – .14½	.14¾ – .15¼
Zinc chloride, gran.	lb.	.07 – .07½	.07¾ – .08
Zinc cyanide	lb.	.42 – .44	.45 – .47
Zinc oxide, XX	lb.	.07½ – .08	.08¼ – .08¾
Zinc sulphate	100 lb.	2.75 – 3.00	3.05 – 3.30

Coal-Tar Products

NOTE—These prices are for original packages in large quantities f.o.b. N.Y.:

Alpha-naphthol, crude	lb.	$0.95 — $1.00
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.29 — .31
Aniline oil, drums extra	lb.	.16 — .17
Aniline salts	lb.	.22 — .24
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Anthracene, 80%, imported in drums, duty paid	lb.	.65 — .70
Benzaldehyde U.S.P.	lb.	1.25 — 1.35
Benzene, pure, water-white, in drums (100 gal.)	gal.	.30 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.28 — .32
Benzene, 90%, in drums, resale	gal.	.37 — .40
Benzidine, base	lb.	.80 — .95
Benzidine sulphate	lb	.82 — .85
Benzoic acid, U.S.P.	lb.	.77 — .75
Benzoate of soda, U.S.P.	lb.	.5 — .65
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech.	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.55 — .60
Beta-naphthol, tech	lb.	.25 — .26
Beta-naphthyla mine, technical	lb.	1.00 — 1.25
Carbazol	lb.	.75 — .90
Cresol, U. S. P., in drums (100 lb.)	lb.	.14 — .20
Ortho-cresol, in drums (100 lb.)	lb.	.18 — .22
Cresylic acid, 97-99%, straw color, in drums	gal.	.60 — .65
Cresylic acid, 95-97%, dark, in drums	gal.	.55 — 58
Cresylic acid, 97%, resale	gal.	.90 — 95
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.50 — 60
Dimethylaniline	lb.	.36 — .38
Dinitrobenzene	lb.	.20 — .22
Dinitroclorbenzene	lb.	.21 — 22
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.32 — .34
Dinitrotoluene	lb.	.22 — 24
Dip oil, 25%, car lots, in drums	gal.	.25 — 30
Diphenylamine	lb.	.54 — .56
H-acid	lb.	.72 — 75
Meta-phenylenediamine	lb.	.90 — 1.00
Monochlorbenzene	lb.	.08 — .10
Monoethylaniline	lb.	.95 — 1.10
Naphthalene crushed, in bbls.	lb.	.06 — .06½

Naphthalene, flake	lb.	$0.06½ —	$0.07
Naphthalene, balls	lb.	.07½ —	.08
Naphthionate of soda	lb.	.58 —	.65
Naphthionic acid, crude	lb.	.65 —	.70
Nitrobenzene	lb.	.10 —	.12
Nitro-naphthalene	lb.	.30 —	.35
Nitro-toluene	lb.	.15 —	.17
N-W acid	lb.	1.20 —	1.30
Ortho-amidophenol	lb.	2.25 —	2.30
Ortho-dichlor-benzene	lb.	.17 —	.20
Ortho-nitro-phenol	lb.	.85 —	.90
Ortho-nitro-toluene	lb.	.10 —	.12
Ortho-toluidine	lb.	.12 —	.14
Para-amidophenol, base	lb.	1.20 —	1.25
Para-amidophenol, HCl	lb.	1.25 —	1.30
Para-dichlorbenzene	lb.	.17 —	.20
Paranitroaniline	lb.	.72 —	.80
Para-nitrotoluene	lb.	.55 —	.65
Para-phenylenediamine	lb.	1.55 —	1.60
Para-toluidine	lb.	.85 —	.90
Phthalic anhydride	lb.	.35 —	.38
Phenol, U. S. P., drums	lb.	.37 —	.40
Pyridine, domestic	gal.	1.60 —	1.75
Pyridine, imported	gal.	1.40 —	1.60
Resorcinol, technical	lb.	1.50 —	1.55
Resorcinol, pure	lb.	2.00 —	2.10
R-salt	lb.	.55 —	.60
Salicylic acid, tech., in bbls	lb.	.29 —	.31
Salicylic acid, U. S. P	lb.	.35 —	.36
Solvent naphtha, water-white, in drums, 100 gal	gal.	.37 —	.40
Solvent naphtha, crude, heavy, in drums, 100 gal	gal.	.20 —	.23
Sulphanilic acid, crude	lb.	.24 —	.26
Tolidine	lb.	1.20 —	1.30
Toluidine, mixed	lb.	.30 —	.35
Toluene, in tank cars	gal.	.35 —	.37
Toluene, in drums	gal.	.40 —	.43
Xylidines, drums, 100 gal	lb.	.40 —	.45
Xylene, pure, in drums	gal.	.45 —	.50
Xylene, pure, in tank cars	gal.	.45 —	....
Xylene, commercial, in drums, 100 gal	gal.	.40 —	.42
Xylene, commercial, in tank cars	gal.	.30 —	....

Waxes

Prices based on original packages in large quantities f.o.b. N.Y.

Bayberry Wax	lb.	$0.22 —	$0.24
Beeswax, refined, dark	lb.	.30 —	.32
Beeswax, refined, light	lb.	.34 —	.35
Beeswax, pure white	lb.	.36 —	.40
Candellila, wax	lb.	.33 —	.34
Carnauba, No. 1	lb.	.39 —	.40
Carnauba No. 2, North Country	lb.	.24 —	.25
Carnauba, No. 3, North Country	lb.	.17 —	.18
Japan	lb.	.15 —	.15½
Montan, crude	lb.	.03½ —	.04
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.04 —	.04¼
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.02½ —	.02¾
Paraffine waxes, refined, 118-120 m.p.	lb.	.03¼ —	.03½
Paraffine waxes, refined, 125 m.p.	lb.	.03½ —	.03¾
Paraffine waxes, refined, 128-130 m.p.	lb.	.04 —	.04¾
Paraffine waxes, refined, 133-135 m.p.	lb.	.04½ —	.04¾
Paraffine waxes, refined, 135-137 m.p.	lb.	.05 —	.05¼
Stearic acid, single pressed	lb.	.09 —	.09¾
Stearic acid, double pressed	lb.	.09½ —	.09¾
Stearic acid, triple pressed	lb.	.10 —	.10½

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Fertilizers

Ammonium sulphate, f.a.s., N. Y., double bags	100 lb.	3.55	—	3.60
Blood, dried, f.o.b., N. Y	unit	4.60	—	....
Bone, 3 and 50, ground, raw	ton	42.00	—	44.00
Fish scrap, dom., dried, f.o.b. works	unit	3.10	—	3.20
Nitrate of soda	100 lb.	2.35	—	2.45
Tankage, high grade, f.o.b. Chicago	unit	4.50	—	4.60
Phosphate rock, f.o.b. mines, Florida pebble, 68-72%	ton	3.50	—	4.00
Tennessee, 78-80%	ton	7.00	—	8.00
Potassium muriate, 80%	ton	33.00	—	34.00
Potassium sulphate	unit	1.00	—	....

Crude Rubber

Para—Upriver fine	lb.	$0.24	—	.24¼
Upriver coarse	lb.	.18	—	.18¼
Upriver caucho ball	lb.	.18½	—	.18¾
Plantation—First latex crepe	lb.	.24	—	.24¼
Ribbed smoked sheets	lb.	.24	—	.24¼
Brown crepe, thin, clean	lb.	.20	—	.20¼
Amber crepe No. 1	lb.	.20	—	.20¼

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls	lb.	$0.12	—	$0.12
Castor oil, AA, in bbls	lb.	.12½	—	.13
China wood oil, in bbls	lb.	.12½	—	.12
Coconut oil, Ceylon grade, in bbls	lb.	.08¾	—	.08¾
Coconut oil, Cochin grade, in bbls	lb.	.08¾	—	.09
Corn oil, crude, in bbls	lb.	.10¼	—	.10¼
Cottonseed oil, crude (f. o. b. mill)	lb.	.08½	—	....
Cottonseed oil, summer yellow	lb.	.11	—	.11¼
Cottonseed oil, winter yellow	lb.	.12	—	.12½
Linseed oil, raw, car lots (domestic) bbls	gal.	.86	—	.87
Linseed oil, raw, tank cars (domestic)	gal.	.82	—	.83
Linseed oil, boiled, in 5-bbl lots (domestic)	gal.	.86	—	.88
Olive oil, denatured	gal.	1.15	—	1.17
Palm, Lagos	lb.	.07½	—	.07¾
Palm, Niger	lb.	.06¾	—	.07
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.10	—	.10¼
Peanut oil, refined, in bbls	lb.	.13½	—	.13¾
Rapeseed oil, refined in bbls	gal.	.77	—	.78
Rapeseed oil, blown, in bbls	gal.	.84	—	.85
Soya bean oil (Manchurian), in bbls. N. Y	lb.	.11½	—	....
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.09	—	.09¼

Miscellaneous Materials

Shellac, orange fine	lb.	74	—	.75
Shellac, orange superfine	lb.	76	—	.77
Shellac, A. C. garnet	lb.	.75	—	.77
Shellac, T. N	lb.	.72	—	73

Other prices remain same as previous report.

Refractories

Bauxite brick, 56% Al_2O_3, f.o.b. Pittsburgh	per ton	$45–50
Chrome brick, f.o.b. Eastern shipping points	net ton	50
Chrome cement, 40-50% Cr_2O_3	net ton	23–27
Chrome cement, 40-45% Cr_2O_3, sacks, in car lots, f.o.b., Eastern shipping points	net ton	23.00
Fireclay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works	1,000	43–46
Fireclay brick, 2nd quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works	1,000	39–41
Magnesite brick, 9-in. straight (f.o.b. works)	net ton	75–80
Magnesite brick, 9-in. arches, wedges and keys	net ton	85–90
Magnesite brick, soaps and splits	net ton	90
Silica brick, 9-in. sizes, f.o.b. Chicago district	1,000	48–50
Silica brick, 9-in. sizes, f.o.b. Birmingham district	1,000	50–53
Silica brick, 9-in. sizes, f.o.b. Mt. Union, Pa	1,000	45–47
Silicon carbide refractory brick, 9-in	1,000	1100.00

Ferro-Alloys

Ferrotitanium, 15-18%, f.o.b. Niagara Falls, N. Y	net ton	$200.00	—	$225.00
Ferrochromium, per lb. of Cr contained, 6-8% carbon, carlots	lb.	.10	—	.10½
Ferrochromium, per lb. of Cr contained, 4-6% carbon, carlots	lb.	.10½	—	.11
Ferromanganese, 78-82% Mn, Atlantic seaboard	gross ton	67.50	—	69.00
Spiegeleisen, 19-21% Mn	gross ton	39.00	—	40.00
Ferromolybdenum, 50-60% Mo, per lb. of Mo	lb.	2.00	—	2.25
Ferrosilicon, 10-15%	gross ton	38.00	—	40.00
Ferrosilicon, 50%	gross ton	63 00	—	65.00
Ferrosilicon 75%	gross ton	115.00	—	120.00
Ferrotungsten, 70-80%, per lb. of contained W	lb.	.85	—	.90
Ferro-uranium, 35-50% of U, per lb. of U content	lb.	6.00	—	.....
Ferrovanadium, 30-40% per lb. of contained V.	lb.	3.50	—	4.00

Ores and Semi-finished Products

Coke, foundry, f.o.b. ovens	net ton	8.00	—	9 00
Coke, furnace, f.o.b. ovens	net ton	6.75	—	7.00

Other Quotations Remain Same as Previous Report.

Non-Ferrous Metals

All f.o.b. New York Unless Otherwise Stated

	Cents per Lb.
Copper, electrolytic	13.875
Aluminum, 98 to 99 per cent	20.00-21.00
Antimony, wholesale lots, Chinese and Japanese	6 60
Nickel, ordinary (ingot)	36.00
Nickel, electrolytic	39.00
Nickel, electrolytic, resale	32.00–33.00
Nickel, ingot and shot, resale	30.00–31.00
Monel metal, shot and blocks	32.00
Monel metal, ingots	35.00
Monel metal, sheet bars	38 00
Tin, 5-ton lots, Straits	37.125
Lead, New York, spot	7.05
Lead, E. St. Louis, spot	6 90
Zinc, spot, New York	7.275–7.325
Zinc, spot, E. St. Louis	6.95–7.00

Silver (commercial)	oz.	$0.64¾
Cadmium	lb.	1.15
Bismuth (500 lb. lots)	lb.	2.45
Cobalt	lb.	3.00@3.25
Magnesium, ingots, 99 per cent	lb.	1.00@1.05
Platinum	oz.	$108.00
Iridium	oz.	240.00@275.00
Palladium	oz.	52.00@55 00
Mercury	75 lb.	72.00

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Arkansas

EL DORADO—The Lion Oil & Refining Co., 624 Finance Bldg., Kansas City, Mo., has arranged an appropriation of about $400,000 for the extensions and improvements in its local oil refinery, previously announced. A complete new plant unit will be constructed to increase the output to 8,000 bbl. per day. A 17-mile pipe line, with pumping plans, will also be built. Victor H. Smith is vice-president and general manager.

California

EMERYVILLE—The American Rubber Co. has awarded a contract to R. W. Littlefield, 351 12th St., Oakland, for the erection of a new 1-story plant at Emery and Park Sts., to cost about $25,000.

FRESNO—The Fresno Paper Co. has plans nearing completion for the erection of a new mill for the production of paper and paperboard, to be equipped for a capacity of 40 tons per day, estimated to cost in excess of $400,000, with machinery.

LOS ANGELES—The Pacific Coast Borax Co., Kohl Bldg., San Francisco, will take bids late in December for its proposed new 2-story refining plant in the Harbor District, Wilmington, 250x400 ft., estimated to cost close to $1,000,000, with machinery, power house, etc. Albert C. Martin, Higgins Bldg., Los Angeles, is architect.

Colorado

DENVER—The Colfax Pressed Brick Co., Clay St., has tentative plans under consideration for the rebuilding of the portion of its plant, destroyed by fire, Nov. 4, with loss approximating $30,000, including equipment.

Connecticut

STAMFORD—Richards & Co., Inc., a subsidiary of the Darco Corp., manufacturer of decolorizing carbons, guncotton products, etc., will commence the immediate erection of a new building at its plant, 26x30 ft., to be equipped for lacquer service and experimental work.

STAMFORD—The Charles H. Phillips Chemical Co. has construction in progress on a new 2-story operating and service building, with machine shop and power house.

ROCKY HILL — Supplementing a 1-story structure, placed in course of erection a few weeks ago, the Connecticut Foundry, Inc., has awarded another contract to C. P. Waterman, Inc., Hartford, Conn., for a new 2-story foundry, 30x70 ft.

Delaware

WILMINGTON—The Hammond Oil Products Co., recently organized, is planning for the erection of a new oil-manufacturing plant on site in the vicinity of the Brandywine River. Application has been made to the Board of Water Commissioners for water supply for the works.

Georgia

COLUMBUS—The W. C. Bradley Co. has acquired the local plant of the F. S. Royster Co., and will make improvements and extensions in the structure for the manufacture of fertilizer products. The factory will be used to replace the plant of the purchaser destroyed by fire a number of months ago.

MACON—The Chamber of Commerce is considering plans for the establishment of a local plant for the manufacture of calcium arsenate and kindred products. A company will be formed to operate the factory.

Idaho

WALLACE—The Galena Mining Co., a subsidiary of the Callahan Zinc-Lead Co., operating in the Coeur d'Alene district, is considering tentative plans for the installation of additional milling machinery and other equipment at its plant.

Illinois

GRANITE CITY—The National Enameling & Stamping Co. has foundations in progress for its proposed new 1- and 2-story sheet steel mill, adjoining its present works, estimated to cost in excess of $1,000,000, including machinery. The United Engineering & Foundry Co., Farmers' Bank Bldg., Pittsburgh, Pa., is in charge of construction. George W. Niedringhous is president.

Indiana

WARSAW—The D. J. Dalton Co. is planning for the rebuilding of its local foundry, partly destroyed by fire, Oct. 31, with loss estimated in excess of $15,000, including buildings and equipment.

INDIANAPOLIS—The Pure Oil Co. has acquired the local distributing plant of the Tiona Refining Co., located on a 4-acre tract of property on Madison Ave., and plans for extensions and improvements. Headquarters of the purchasing company are in the Pure Oil Bldg., Columbus, O.

Kentucky

LOUISVILLE—The National Forge Co., 1572 Cherokee Road, will commence the immediate construction of a new 1-story foundry for the production of iron castings, 60x120 ft., estimated to cost close to $15,000, exclusive of main equipment, to be located on Garland Ave. Whitfield Clark is president.

Louisiana

SWARTZ—The Atlas Oil Co. plans for the rebuilding of its gasoline-refining plant, destroyed by fire, Oct. 31, with loss estimated at about $100,000, including machinery.

Maryland

BALTIMORE—The Johns Hopkins University, Homewood, has plans in progress for the erection of its proposed 2- and 3-story chemical laboratory, and will call for bids in the near future. Carrere & Hastings, 52 Vanderbilt Ave., New York, are architects.

BALTIMORE — The Union Chemical Co., formerly of Philadelphia, Pa., has acquired a building at 621 South Regester St., for a new plant. The present works will be removed to this location.

BALTIMORE—The Red "C" Oil Co., Keyser Bldg., is taking bids for the construction of a 1-story plant addition at the Key Highway and Lawrence St., 70x70 ft. W. W. Pagon, Lexington Bldg., is engineer.

Massachusetts

WHITINSVILLE—The Kupfer Brothers Co., 112 Wooster St., New York, N. Y., manufacturer of coated papers and other paper stock, has awarded a contract to the E. D. Ward Co., Worcester, for the erection of a large addition to its Riverdale mill, Whitinsville.

EAST LONGMEADOW — The New England Steel Casting Co., 100 School St., Springfield, will hold in temporary abeyance the rebuilding of its foundry at East Longmeadow, destroyed by fire several months ago. When the work is authorized, the proposed structure will be 1-story, 70x125 ft., estimated to cost approximately $50,000. Morris W. Maloney, 145 Chestnut St., Springfield, is architect.

CAMBRIDGE — The United States Tire & Rubber Co., 560 Commonwealth Ave., Boston, has commenced foundations for a new plant at 660 Charles River Rd., 84x135 ft., estimated to cost $100,000, including equipment. The structure will be occupied under lease. F. A. Norcross, 46 Cornhill St., Boston, is architect.

SPENCER—The Spencer Gas Co., 110 Main St., is considering the erection of an addition to its artificial gas plant on Elm St., to cost about $45,000. W. M. Russell, 77 Franklin St., Boston, is architect.

Michigan

DETROIT—The Charles B. Bohn Foundry Co., 3651 Hart St., manufacturer of brass, bronze and kindred metal castings, has plans in progress for a new plant addition.

MUSKEGON—The Central Paper Co. has completed plans for the erection of a new 3-story addition to its plant on Lake St., to cost about $22,000, exclusive of equipment. The company has disposed of a bond issue of $1,100,000, a portion of the proceeds to be used for expansion.

Minnesota

RED WING—The Red Wing Sewer Pipe Co., manufacturer of vitrified pipe, has tentative plans under consideration for the rebuilding of the portion of its plant, destroyed by fire, Nov. 1, with loss estimated at $150,000, with machinery.

Missouri

SPRINGFIELD—Immediately upon completion of its initial plant unit, 100x135 ft. on West Commercial St., now in course of erection, the Springfield Tanning Co., will commence the erection of a new 1-story and basement adjoining works, 60x100 ft. Headquarters of the company are at 214 Holland Bldg., Springfield. W. R. Wolfe is head.

New Jersey

CAMDEN—The Camden Pottery Co., manufacturer of sanitary earthenware, has awarded a contract to E. R. Hall, 34 South 17th St., Philadelphia, Pa., for the erection of a 2-story addition, 70x140 ft., estimated to cost approximately $30,000, to be located at Mt. Vernon and Mt. Ephraim Aves.

PLAINFIELD—The British-American Metals Co., 200 Broadway, New York, N. Y., manufacturer of metals and metal alloys, has awarded a contract to the Levering & Garrigues Co., 552 West 23rd St., for the erection of a 1-story addition, 40x150 ft., to its plant on South 2nd St., Plainfield, estimated to cost about $27,000. N. A. Staples is vice-president.

WAYNE—E. I. du Pont de Nemours & Co., Wilmington, Del., have discontinued operations at their local plant, used for the manufacture of naval powder, and will close the works permanently. The equipment will be removed to Beeling, Pa., where a similar plant is now being operated, the capacity of which will be increased.

TRENTON—The Enterprise Tire & Rubber Co., North Clinton Ave., has filed plans for the erection of a 1-story addition to its plant.

New York

COHOES—Fire, Nov. 4, damaged a portion of the plant of the Peerless Fibre Co., Ontario St., with loss approximating $10,000. It will be rebuilt.

North Carolina

CHARLOTTE — The American Machinery Equipment Co., Providence Rd., Myers Park, machinery dealer, is making inquiries for a quantity of chemical equipment for installation in a local plant.

Oklahoma

BARTLESVILLE — The Phillips Petroleum Co., operating gasoline refineries, has acquired two local gasoline absorption plants, heretofore operated by Waite Phillips. The new owner will take possession immediately, and plans for extensions and improvements in the plants.

TULSA—The local plants of the Pure Oil Co., the Tidal Oil Co. and the Roxana Oil & Gas Co. were partly destroyed as a result of a recent tornado, with aggregate loss estimated in excess of $600,000, including equipment. The mills will be rebuilt.

Pennsylvania

MARCUS HOOK — The Sun Co., Finance Bldg., Philadelphia, Pa., has plans under consideration for the erection of an addition to its oil refinery at Marcus Hook, in the vicinity of 7th and Green Sts., to increase the output by about 10 per cent. J. Howard Pew is president.

PHILADELPHIA—The Paper Manufacturers' Co., 826 Cherry St., has awarded a contract to the J. S. Rogers Co., Drexel Bldg., for the erection of a new 6-story plant at 5th and Willow Streets, 127x180 ft., estimated to cost close to $500,000, including equipment.

NEW CASTLE—The National Radiator Co. will commence the immediate erection of a 1-story foundry addition, 30x365 ft. A list of equipment for installation will be arranged at an early date. Headquarters of the company are at Johnstown, Pa.

NORRISTOWN—E. F. Woodhead, Swarthmore, Pa., has acquired the local plant of the Norristown Coal & Ice Co., vacated some time ago, and will remodel and improve the structure for a paper mill. Equipment will be installed at an early date.

NEWPORT—Fire, Nov. 8, destroyed a large portion of the plant of the Mineral Products Co., East Newport, manufacturer of prepared roofing specialties, with loss estimated at about $25,000, including equipment. John R. Morgan is head.

PHILADELPHIA—The Foreign Trade Bureau, Philadelphia Commercial Museum, 34th St., is in receipt of an inquiry from a company at Alexandria, Egypt, desiring to purchase equipment for a cottonseed oil mill, with capacity of 35 to 40 tons of cottonseed per 24 hours. Full information available upon request.

Rhode Island

PAWTUCKET — The Whatcheer Chemical Co., manufacturer of soaps, fertilizers, etc., has tentative plans under consideration for the rebuilding of its plant, destroyed by fire, Nov. 7, with loss estimated at close to $200,000, including machinery.

South Carolina

CLOVER—J. F. Pursley, Clover, is planning for the organization of a company to establish and operate a local mill for the manufacture of fertilizer products.

Texas

PASADENA — The Stauffer Chemical Co., Freeport, Tex., has acquired a tract of land near the Houston ship channel, Pasadena, totaling about 30 acres, as a site for a new plant for sulphur refining. Plans will be prepared at an early date.

TEXAS CITY—The Terminal Oil & Refining Co. is perfecting plans for its proposed local plant extensions, to include additional units at the topping works for the handling of 15,000 bbl. of crude oil daily, and the construction of 9 steel storage tanks. Considerable new machinery will be installed.

KENEDY—E. L. Patilo, Kenedy, is perfecting arrangements for the establishment of a local plant for the manufacture of soaps, washing powders, etc.

Virginia

STUART—S. A. Thompson, Stuart, is organizing a company for the development of mica properties in this section. A grinding mill and other equipment will be installed.

NORFOLK—Fire, No. 5, destroyed a large portion of the fertilizer manufacturing plant of the Fisheries Products Co., Money Point, Norfolk, with loss estimated at about $300,000, including machinery and stock. Preliminary plans for rebuilding are under consideration.

NEWPORT NEWS—A chemical laboratory will be installed in the new local high school to be erected by the School Trustees at 31st and Hungtington Ave., to be 3-story, 196x220 ft., estimated to cost approximately $600,000.

LEXINGTON — The Washington and Lee University has plans nearing completion for a new chemical laboratory building, estimated to cost about $110,000. Flournoy & Flournoy, Union Trust Bldg., are architects.

Washington

EDMONDS—The Union Oil Co., Seattle, has surveys in progress for the construction of a new oil-distributing and storage plant at Ten-Mile Point, near Edmonds, where a 20-acre tract of land has been obtained. Estimated to cost about $500,000, with equipment. The new works will supplant the present Seattle station.

West Virginia

WHEELING—The Interstate Oxygen Co., 4th St., has awarded a contract to H. L. Bearight, Wheeling, for the erection of a 1-story plant addition, 100x150 ft., estimated to cost in excess of $50,000, including equipment.

WEIRTON — The Weirton Steel Co. will commence the immediate construction of a new byproducts coke plant estimated to cost approximately $3,000,000. The Koppers Co., Union Arcade, Pittsburgh, Pa., is engineer and contractor.

PENNSBORO—John B. Yates, vice-president of the Premier Window Glass Co., with local plant, has acquired the factory of the Pioneer Window Glass Co., West View, Marietta, O. Possession will be taken immediately and improvements made. It is planned to resume operations at the plant early in the coming year.

Wyoming

RAWLINGS—The Producers' & Refiners' Corp., California Bldg., Denver, Colo., has selected a site at Greensville, near Rawlins, for its proposed new oil refinery, and has plans in progress for the initial unit. It will have a capacity of about 10,000 bbl. per day, and which will be increased to 25,000 bbl., with the erection of additional units at a later date. A pipeline will be constructed from the Ferris oil fields to the site. The company has also arranged for the construction of new storage and distributing plants at Ferris and Wertz.

Canada

ST. JOHN, N. B.—The Stephen Brick Co., Ltd., has tentative plans under consideration for the rebuilding of its plant at Little River, destroyed by fire, Nov. 5, with loss approximating $100,000, including equipment. The plant was practically new and only in service for a few months.

VANCOUVER, B. C.—The Powell River Co., Ltd., has preliminary plans under consideration for the erection of a large new unit at its paper mill, and addition to the power plant. The work is estimated to cost approximately $3,000,000.

VICTORIA, B. C.—The Seaman Paper Co., 208 South La Salle St., Chicago, Ill., in conjunction with the Bridge River Power Co., Victoria, and affiliated interests, is formulating plans for the construction of a new pulp and paper mill at Seton Lake, estimated to cost in excess of $750,000.

Industrial Developments

GLASS — The Scott-Warman Glass Co., East Stroudsburg, Pa., is completing the rebuilding of its plant destroyed by fire some time ago, and plans to place the works in service within the next fortnight. The company specializes in the manufacture of hollowware.

The Premier Window Glass Co., Pennsboro, W. Va., is perfecting plans for a resumption of operations at its plant about Jan. 1, giving employment to close to the maximum of 200 men.

Window glass plants in western Pennsylvania and eastern Ohio are granting a 10 per cent wage advance to operatives.

LEATHER—The William Amer Co., Philadelphia, Pa., is operating its tannery at full capacity, with incoming orders insuring continuance for some time to come.

Dungan, Hood & Co., Philadelphia, Pa., are running at approximately 75 per cent of normal at their local tanning plant.

The Castle Kid Co., Camden, N. J., is running full at its tannery, with heavy domestic and export orders for future delivery. Kid and cabrettas are the main items of production.

The Keystone Leather Co., Philadelphia, Pa., is advancing production at its plant.

Burk Brothers, Philadelphia, Pa., are operating on a basis of 65 to 75 per cent of normal at their tanneries.

C. J. Matthews & Co., Philadelphia, Pa., specializing in the production of glazed kid, are running in excess of 60 per cent of capacity at their tannery, and have orders on hand to insure this schedule for a number of months ahead.

METALS—The New Jersey Zinc Co., Palmerton, Pa., has placed two additional spelter furnaces in service at its local plant.

The International Nickel Co., New York, is advancing production at its new plant at Huntington, W. Va. Present sales are averaging about 1,500,000 lb. of nickel monthly and 400,000 lb. of Monel metal.

The Boston & Montana Corp., Butte, Mont., is arranging for the immediate resumption of operations at its local mill.

The Calumet & Hecla Co., Calumet, Mich., is advancing production at its smelting plant, which has been operating on a basis of about 80 per cent of capacity. Repairs have been completed to the furnaces at the electrolytic plant and increased output is being arranged.

The Ray Consolidated Mining Co., Ray, Ariz., is increasing shipments to its concentrating plant and a basis of approximately 2,500 tons a day has been established.

The Nevada Consolidated Copper Co., Ely, Nev., has placed two additional mills in service, making four mills now operating at the plant. It is planned to add two more mills by the close of the month.

The United Verde Extension, Jerome, Ariz., is developing a production of 3,000,000 lb. of copper per month at its plant, and expects to maintain this output for an indefinite period.

IRON AND STEEL—The Bethlehem Steel Co. is increasing production at its Steelton, Pa., works, and adding to the operating force. Practically all departments are now running on a full time schedule.

The Alan Wood Iron & Steel Co., Conshohocken, Pa., has postponed the blowing in of its No. 3 stack, recently announced, and will defer operations at the furnace until Jan. 1.

The Tennessee Coal, Iron & Railroad Co., Birmingham, Ala., has placed its tie plate mill on a double turn, and expects to maintain this basis of operation for an indefinite period.

The Eastern Steel Co., Pottstown, Pa., relighted its furnace No. 1 on Nov. 9, following an inactivity of about 24 months. Repairs and improvements have been made to the unit during the curtailment. It is expected to maintain production for an indefinite time. The No. 2 furnace of the company at Swedeland, Pa., is still idle; it was shut down last July owing to coke shortage.

The Lavino Furnace Co., Philadelphia, Pa., affiliated with E. J. Lavino & Co., is arranging to change production at its Sheridan furnace from foundry iron to ferromanganese.

The Reading Iron Co., Reading, Pa., is maintaining full production at its different mills. The wages of puddlers have been advanced from $8 to $8.80 a ton. The increase affects about 600 men, engaged at the Reading, Columbia and Pottstown, Pa., mills.

The Claire Furnace Co., Youngstown, Pa., is arranging for the early resumption of operations at its blast furnace. This addition will make an active list of 31 furnaces out of a total of 47 in the Youngstown district.

The United States Steel Corp. has advanced production 5 to 7 per cent at its mills at Gary, Ind., during the past fortnight. The Illinois Steel Co., a division of the Gary mills, is running on a basis of 75 to 80 per cent of capacity.

MISCELLANEOUS—Paper mills at Monroe, Mich., are developing maximum capacities. Four plants devoted to boxboard production have adopted a night shift in addition to regular day operations, and are turning out about 1,000 tons of material per day.

The Procter & Gamble Co., Cleveland, O., manufacturer of soaps, powders, etc., is operating its four plants on a capacity basis, located at Cleveland; Port Ivory, Staten Island; Kansas City, Mo.; and Dallas, Tex. A wage advance has been made covering all plants, affecting about 10,000 workers. It will approximate $250,000 a year, gross.

The Trans-Continental Oil Co., Bristow, Okla., is completing its new local oil-refining plant, and will place the unit in service at an early date. It will have a capacity of 5,000 bbl. a day, and will increase the company's refinery production to 14,000 bbl. daily, maximum.

The National Fireproofing Co., Pittsburgh, Pa., manufacturer of hollow tile and other kindred burned clay products, is operating its plants at from 80 to 85 per cent of capacity, and has orders on hand and in prospect to maintain this basis of production for the next 12 months.

The H. C. Frick Co., Connellsville, Pa., has placed its Leith plant in operation after a shut-down for about 5 months past. All company plants in Fayette, Westmoreland and Greene Counties are now in service, and practically on a 100 per cent basis.

The Interstate and Foreign Trade Department, Chicago Association of Commerce, 10 South La Salle St., Chicago, Ill., reports an inquiry (No. 1605) from the Shanghai, China, branch of an American company, for a first-class chemist and engineer for the local office at Shanghai.

Capital Increases, etc.

THE ACME RUBBER MFG. CO., Trenton, N. J., manufacturer of mechanical rubber products, has filed notice of increase in capital from $500,000 to $2,000,000.

THE EMPIRE REFINING CO. OF DELAWARE, Oklahoma City, Okla., has filed notice of increase in capital from $2,750,000 to $4,850,000.

THE UNION STARCH & REFINING CO., Edinburg, Ind., has arranged for an increase in capital from $340,000 to $2,000,000 for expansion. A plant has recently been acquired at Columbus, Ind., and operations will be transferred to that location.

THE CHICKASAW REFINING CO., 60 Broadway, New York, N. Y., manufacturer of petroleum products, a Delaware corporation, has filed notice of reduction in capital from $10,000,000 to $2,500,000.

THE GENERAL CHEMICAL CORP., Detroit, Mich., has filed notice of dissolution under state laws.

THE MILLER & WRIGHT PAPER CO., 65 Duane St., New York, N. Y., has filed notice of increase in capital from $50,000 to $400,000.

THE CAMAGUEY SUGAR CO., George H. Houston, president, 60 Broadway, New York, N. Y., operating sugar refining plants in Cuba, has disposed of a bond issue of $6,000,000, a portion of the proceeds to be used for general operations, financing, etc.

THE ATLAS STEEL CORP., Dunkirk, N. Y., has arranged for a stock issue of $6,500,000 preferred, and 100,000 shares of common stock, no par value, a portion of the proceeds to be used for plant operations, financing and expansion.

THE GREAT NORTHERN PAPER CO., Madison, Me., is arranging for an increase in capital from $8,300,000 to $25,000,000, a portion of the proceeds to be used for general operations and expansion.

E. I. DU PONT DE NEMOURS & CO., Wilmington, Del., manufacturers of powder chemicals, etc., are perfecting plans for an increase in capital from $80,000,000 to $100,000,000.

THE SOLAR REFINING CO., Lima, O., manufacturer of oil products, will increase its capital from $2,000,000 to $4,000,000, for proposed expansion.

New Companies

THE NATIONAL CARBON COATED PAPER CO., Sturgis, Mich., has been incorporated with a capital of $650,000, to manufacture coated and other papers. The incorporators are James G. Van Horn, D. A. Hopping and C. L. Spence, 128 South Nottawa St., Sturgis. The last noted represents the company.

THE BUFFALO REFINING CO., Sherman, Tex., has been incorporated with a capital of $75,000, to manufacture refined oil products. The incorporators are F. M. Thompson, D. L. Cooke and B. F. Smith, all of Sherman.

THE REIS RUBBER PRODUCTS CO., care of J. I. Berman, 346 Broadway, New York, N. Y., representative, has been incorporated with a capital of $100,000, to manufacture rubber specialties. The incorporators are A. L. Berman, E. Tumin and A. S. Wechsler.

THE PLYMOUTH ROCK PAINT CO., Boston, Mass., has been incorporated with a capital of $50,000, to manufacture paints, varnishes, etc. Charles C. Mann is president; and Charles J. Landen, 3 Monadnock St., Dorchester, Mass., treasurer and representative.

THE MIDWAY CITY GLASS CORP., Huntington, W. Va., has been incorporated with a capital of $50,000, to manufacture glass products. The incorporators are B. W. Walton, N. Christian and R. T. Morris, all of Huntington.

THE PALATKA CLAY PRODUCTS CO., Palatka, Fla., care of the United States Corporation Co., 65 Cedar St., New York, N. Y., representative, has been incorporated under Delaware laws with capital of $300,000, to manufacture burned clay products. The incorporators are Robert W. Lyle, Keasby, N. J.; Elliott Norton, New York; and Alexander H. Jackson, Rutherford, N. J.

THE ALLOYS FOUNDRY CO., Room 750, 407 South Dearborn St., Chicago, Ill., has been incorporated with a nominal capital of $6,000, to manufacture special castings and kindred metal products. The incorporators are Charles B. Carter, Samuel W. Booth, Jr., and Allen Erikson.

THE HATFIELD RUBBER WORKS, INC., Newark, N. J., has been incorporated with a capital of $250,000, to manufacture rubber tubing and other rubber products. The incorporators are Andrew L. Hatfield, Abraham and Louis Beller, 92 Academy St., Newark. The last noted represents the company.

THE MISSISSIPPI VALLEY PETROLEUM CO., care of the Delaware Registration Trust Co., 900 Market St., Wilmington, Del., representative, has been incorporated under Delaware laws with a capital of $125,000, to manufacture petroleum products.

THE SIMPSON-COHEN-BOESCH CO., Hartford, Conn., has been incorporated with a capital of $50,000, to manufacture chemicals and chemical byproducts. The incorporators are H. I. Cohen, George Boesch and George L. Simpson, 391 Albany Ave., Hartford. The last noted represents the company.

THE COMMERCIAL IRON WORKS, INC., Portland, Ore., has been incorporated with a capital of $100,000, to operate a foundry for the production of iron, steel and other metal castings. The principal incorporator is William T. Casey. The company is represented by John M. Joyce, 606 Concord Bldg., Portland.

HOLTAGE & REMINGTON, INC., Providence, R. I., has been incorporated with a capital of 100 shares of stock, no par value, to manufacture refined metals. The incorporators are B. A. Remington, Wallace Holgate and Ernest C. Baker, 60 Harvard St., Providence.

THE GATTI PAPER STOCK CO., New York, N. Y., care of Smith & Bowman, 38 Park Row, New York, representative, has been incorporated with a capital of $200,000, to manufacture paper products. The incorporators are H. Cowan, W. Meighan and N. H. Bowman.

THE RAY RUBBER PRODUCTS CO., Irvington, Newark, N. J., has been incorporated with a capital of $10,000, to manufacture rubber goods. The incorporators are E. A. London, Thomas J. Ryan and Daniel R. Smith, 54 Woolsey St., Irvington. The last noted represents the company.

THE CALUMET BAKING POWDER CO., 4400 Filmore St., Chicago, Ill., has been incorporated with a capital of $8,500,000, to manufacture baking powder. The company is now operating a local plant. The incorporators are Frederic O. Mason, Warren Wright and Sidney S. Gorham.

THE COMMODORE OIL CO., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., has been incorporated under Delaware laws with capital of $3,000,000, to manufacture petroleum products.

PAPER PRODUCTS, INC., Mechanic Falls, Me., has been incorporated with a capital of $10,000, to manufacture paper specialties. Ralph T. Parker is president, and Leroi G. Limerick clerk and representative, both of Mechanic Falls.

THE SEMI-STEEL CASTING CO., St. Louis, Mo., has been incorporated with a capital of $15,000, to manufacture steel alloy and other metal castings. The incorporators are J. H. Connor and C. F. Storckman, both of St. Louis.

THE UNITED LABORATORIES, 36 Clinton St., Newark, N. J., has filed notice of organization to manufacture chemical specialties. The company is headed by Herman G. Fauer and William H. Robinson, 10 Ridgewood Ave., Newark.

THE WHITEHOUSE PRODUCTS CO., 564 West Randolph St., Chicago, Ill., has been incorporated with a capital of $5,100, to manufacture chemical specialties. The incorporators are E. F. Menkin and Leo B. Samuels.

THE BARBERS' HILL OIL CO., New York, N. Y., care of H. P. Freece, 35 Wall St., New York, representative, has been incorporated with a capital of $100,000, to manufacture oil products. The incorporators are R. Constantian and C. O. Dunaway.

THE REPUBLIC GLASS CO., Monroe, Mich., has been incorporated with a capital of $150,000, to manufacture glass products. A local plant has been completed and operations will be started at once. The incorporators are Manuel M. Llera, William N. Mathews and Thornton Dixon, Monroe.

L. DEL TURCO & BROTHERS, INC., Newark, N. J., care of Toby Furst, 164 Market St., Newark, representative, has been incorporated with a capital of $100,000, to manufacture ceramic tile and kindred products. The incorporators are Louis and Peter Del Turco.

THE RELIABLE CHEMICAL & EXTERMINATING CO., New York, N. Y., care of H. N. Herber, 23 West 31st St., New York, representative, has been incorporated with a capital of $25,000, to manufacture chemicals and affiliated products. The incorporators are C. Zanisek and M. M. Marcus.

THE WESTERN KENTUCKY REFINERY, INC., Warren, Ky., has been incorporated with a capital of $10,000, to manufacture petroleum products. The incorporators are J. Robert Kirby and Kirk Massey, both of Smiths Grove Ky.; and John B. Rhodes, Bowling Green. Ky.

THE SEMPLE MFG. CO., Trenton, N. J., has been incorporated with a capital of $100,000, to manufacture rubber specialties, tubing, etc. The incorporators are L. Bathews, George T. Nutt and Charles H. Semple, Brookville, Trenton. The last noted represents the company.

THE EASTERN ELECTROCHEMICAL CO., Brooklyn, N. Y., care of M. D. Bohrar, 154 Nassau St., New York, representative, has been incorporated with a capital of $20,000, to manufacture chemicals and chemical byproducts. The incorporators are D. Goldklang, F. Paul and M. Loris.

THE KING LOUIS OIL CO., INC., Worcester, Mass., has been incorporated with a capital of $100,000, to manufacture oil products. Zephire Lagasse is president and M. R. Lagasse, 17 Dean St., treasurer. The last noted represents the company.

THE NORTHERN NEW JERSEY OIL CO., Montclair, N. J., has been incorporated with a capital of $50,000, to manufacture and deal in petroleum products. The incorporators are H. Russ Van Vleck, Arthur B. Marvin and Henry W. Trimble, 483 Bloomfield Ave., Montclair. The last noted represents the company.

THE INTERNATIONAL CHEMICAL CO., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws with a capital of $500,000, to manufacture chemicals and chemical byproducts.

THE AMERICAN MOULDED COMPOSITION CO., 1-5 Market Sq., Lynn, Mass., has filed notice of organization to manufacture composition insulation products. The company is headed by Thomas J. Cannon.

THE PEERLESS PAPER SPECIALTY CO., Brooklyn, N. Y., care of Myer Efros, 25 West 43rd St., New York, representative, has been incorporated with a capital of $30,000, to manufacture paper products. The incorporators are S. J. Rosenthal, B. Mossman and A. Robbins.

THE IMPERIAL OIL CO., Tampa, Fla., has been incorporated with a capital of $100,000, to manufacture oil products. W. F. Miller is president; A. Murray Allen, vice-president; and B. L. Hammer, secretary, all of Tampa.

THE MASON-GIBBS CORP., Buffalo, N. Y., care of Arthur J. Adler, Erie County Bank Bldg., Buffalo, representative, has been incorporated with a capital of $5,000, to manufacture chemicals and affiliated products. The incorporators are A. H. Mason and W. E. Gibbs.

THE JAMES A. MUIR CO., Whippany, N. J., has been incorporated with a capital of $100,000, to manufacture paper and paperboard products. The incorporators are E. R., Louis, and James A. Muir, Jefferson Station, Whippany. The last noted represents the company.

THE AMERICAN INTERNATIONAL OIL CORP., New York, N. Y., care of the Registrar & Transfer Co., 900 Market St., Wilmington, Del., representative, has been incorporated under Delaware laws with a capital of $3,000,000, to manufacture petroleum products.

THE H. R. KUHNHARDT, JR. CORP., New York, N. Y., care of Max Schenkman, 56 Pine St., New York, representative, has been incorporated with a capital of $400,000, to operate a metal refining plant. The incorporators are W. W. Wait, E. Armstrong and L. Debrigard.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its annual meeting in Pittsburgh, Pa., Feb. 12 to 17, 1923.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting April 3 to 7, 1923, at New Haven, Conn.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting May 3, 4 and 5, 1923, at the Commodore Hotel, New York City.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its winter meeting at Richmond, Va., Dec. 7 to 9. Headquarters will be at the Hotel Jefferson.

INTERNATIONAL CHAMBER OF COMMERCE will hold its second general meeting in Rome, Italy, March 19-26, 1923.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF CHEMICAL INDUSTRY, American Section, will meet in Rumford Hall, 52 East 41st St., New York City, on Dec. 15.

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, East 41st St., New York City: Dec. 1—Society of Chemical Industry, regular meeting. Dec. 8—American Chemical Society, regular meeting. Jan. 5—American Chemical Society, regular meeting. Jan. 12—Society of Chemical Industry, Perkin Medal. Feb. 9—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting. March 9—American Chemical Society, Nichols Medal. March 23—Society of Chemical Industry, regular meeting. April 20 — Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting. May 4—American Chemical Society, regular meeting. May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting. May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.

Your Support Is Solicited

SEVERAL current developments in Washington are competing for the attention of the chemical public. The Tariff Commission has already begun to unravel the knotty problems involved in the flexible tariff provision on chemicals. The State Department, apparently, is still scheming with dyes and reparations, while Congress and the Internal Revenue Commissioner continue to play football with industrial alcohol. But with these issues furnishing the pyrotechnics, there is a less spectacular development in the Commerce Department which is likely to be overlooked. Our reference is to the rather faltering progress being made by the new chemical commodity division in its efforts to serve our industry.

Four months ago, when the chemical division was organized, we naturally expected great things from it. There appeared to be a definite need in our industries for co-operative study of export problems, foreign markets and competition, and of such domestic questions as standardization, trade statistics and cost finding. The man put in charge of the work was admirably fitted for it, and the different branches of the industry through associations and individuals pledged him their support. In the short time he held that position Mr. DELONG accomplished considerable, but it is now evident that his work was severely hampered. In fact, the meager appropriation allowed the chemical division practically prevented it from filling its true function of constructive service. With but $10,000 for personnel expenses during the present fiscal year, and that to be distributed among two chemists, a clerk and a stenographer, it is evident that the possibilities for startling accomplishments were definitely limited.

But the chemical division is facing a second predicament. Its former chief, Mr. DELONG, has now returned to the Tariff Commission, where his services and experienced judgment were sorely needed in connection with the administration of the new tariff law. To find a successor with a sufficiently broad experience in the chemical industry and at the same time qualified to deal with its foreign trade problems has been one of the Commerce Department's most difficult problems and is yet one that is far from being solved.

It would seem, therefore, that there are two things to be accomplished and for which those in charge may quite logically look to the chemical industry for a helping hand. First and of more immediate importance is the appointment of the division chief. Such a man should know the chemical industry thoroughly, particularly from the business viewpoint; he should be a good organizer, something of a diplomat, and, most important of all, possessed of a generous supply of common sense. In addition, the Commerce Department is anxious that the man should have some experience in foreign trade, but it is our opinion that this is not nearly as essential as a good grounding in the chemical industry as a domestic business. Surely, somewhere a man of these qualifications is available, and we in the industry would be unmindful of our duty if we did not help the department in making this important appointment.

Our second obligation is in the matter of support—financial and otherwise. If the Bureau of Foreign and Domestic Commerce is granted an increased appropriation for the next fiscal year, funds can be made available for strengthening the chemical division so that it can function effectively in serving the chemical industry. Lending approval to Mr. HOOVER'S request of the Congressional Appropriations Committees, therefore, is merely an effort in our own behalf. And in the meantime the industry should continue to stand squarely behind the work of the new division. Its measure of service will depend primarily on whether or not it receives the indorsement and hearty co-operation of all branches of the chemical industry.

Combating Tuberculosis

HEALTH hazards in the chemical industry are usually so definite and well recognized that proper precautions are taken against them. Of a more insidious character, however, and consequently not so thoroughly appreciated is the menace to industry as a whole of the ravages of tuberculosis. Many diseases to which the human animal succumbs take their toll only in the later years of the average span of life. Tuberculosis, on the contrary, is essentially a disease of the producer, for 80 per cent of the deaths from this cause occur in persons between the ages of 15 and 44.

There is a definite personal obligation on executives and technical men in industry to give thought to this industrial health hazard. Enlightened leadership in the elimination of the scourge is afforded through the National Tuberculosis Association, which makes its annual public appeal at the holiday season through the sale of Christmas Seals. There is little need here to describe the splendid work of this association in educating the public to better hygiene or to quote the astounding results achieved—results which in many places have cut in half the mortality from tuberculosis. But it is appropriate and vital for men intimately associated with industry to remember that the wage earner is the most frequent victim of tuberculosis, and industrial leaders must be concerned with the health of the wage earner.

Exposure to dust, smoke fumes and poisonous chemicals as well as poor lighting and ventilation and long hours of labor, all have their effect in undermining the health of the worker and reducing his resistance to

disease. Technical men in many industries have control over these working conditions and should exercise a vigorous, intelligent and sustained effort toward improvement. While this is humanitarian, it may also be regarded as almost selfish, for it has been proved time and again that money invested in improving the health of the worker is more than balanced by a decrease in labor turnover, spoilage of product and lost time due to illness, and by a distinct increase in per capita production. Of all this we are reminded, annually at least, by the appearance of the Christmas Seals, inviting our support for a movement that in the end brings a definite benefit to industry.

An Opportunity for The Fertilizer Division

AT NO TIME in its history has the fertilizer industry needed as much as it does today constructive thought for its highest development. In many respects it stands on the threshold of a new era. Among the agencies that should be making a regular contribution to its progress is the fertilizer division of the American Chemical Society. Representing as it does not only individual chemists of recognized merit but also our largest chemical society, it is in an unusually fortunate position to render service. There is a feeling, however, backed by some evidence, that the division is altogether missing its opportunity.

The program of the recent A.C.S. meeting in Pittsburgh included a series of titles for papers in the fertilizer division that was most impressive. Particularly the group of papers in the symposium on "The Modern Trend of the Fertilizer Industry" promised to be of great interest and value. Performance, however, fell far short of the promise. The forenoon meeting was devoted almost wholly to papers on analytical chemistry in the fertilizer industry, which were presented at painful length and in much greater detail than the circumstances justified. The afternoon session, which was to include the symposium, suffered even more acutely by the fact that only two of the six speakers in the symposium were present. Of the remaining four papers, two could not be presented at all because neither author nor paper were on hand. Finally, the attendance at this meeting apparently reached low water mark, with an average of less than a dozen for each session.

Three specific criticisms grew out of this meeting, all of which can be profitably considered for the future. First, it has been argued that, on account of the small attendance and the apparent lack of interest, the division should be disbanded. Second, the discussion of analytical methods, while not wholly out of place in the fertilizer division, is not worthy of as much attention as it has received. Third, it was said in some quarters that the division was not going to the root of things, and was playing around on the fringe of an important subject in a way that looked as though it was trying to suppress criticism of the industry.

With the first of these we are not in sympathy, although we should be so inclined if we felt there were no hope for improvement. The fertilizer industry is more and more engaging the attention of competent chemists and engineers and is getting out of the realm of rule of thumb into that of scientific control and operation. Consequently the A.C.S. division should enlist the active co-operation of a large number of important men. The industry already has some excellent leaders, and more good chemists are constantly entering the field. There is need for the division.

Attendance, however, will depend in large measure on the program, which leads us to the second item of criticism. Without decrying the importance of analytical methods, we think it fair to say that they are not the most vital things in the fertilizer industry today. However interesting they may be to those who have to use them, they are dry and tedious to others who have the larger problems of industrial development in view. The proper place for detailed study and debate on methods of fertilizer analysis is in the meetings of the Association of Official Agricultural Chemists. Methods must have their approval before they can be widely adopted. Consequently it is a waste of time to duplicate the work of that association in the fertilizer division of the A.C.S. In our judgment the discussion of analytical methods can well be left to the A.O.A.C. because, being organized for that purpose, it will handle the subject more sympathetically and effectively.

What then shall be the function of the fertilizer division? In our judgment it should discuss the larger aspects of the fertilizer industry as a whole; apparent trends in fertilizer manufacture and application; the future of the industry in 10 to 20 years, as indicated by the general development and the obvious limitations of the present processes and products; the chemistry of raw materials and the methods of treating them, with special reference to new developments; engineering and economic problems involved in the manufacture, transportation, storage and application of fertilizers. A discussion of these and many other similar subjects will give the impression that the division is going to the root of things, and will successfully dispel the notion that the industry wants to suppress criticism of its present methods and does not care to receive suggestions that involve radical changes.

On the whole we have the impression that it would be a backward step to disband the division. There is a vast amount of worth-while work for it to do; but we are equally certain that if it is to justify its existence it must give some thought to its highest functions and take steps to rejuvenate its membership.

The Wisdom Of Fulton

HANGING in a corridor of the Engineers' Club in New York is a document of historic interest, being ROBERT FULTON'S "estimate for the expense of a steam ferryboat for one year." The items are penned in a firm hand, and while the document as a whole shows the effect of age, the paper has not disintegrated nor has the ink faded to a noticeable degree. Dated January 22, 1810, the paper bears the autograph of the famous engineer and inventor.

It is not so much the actual cost of operating a steam ferryboat in 1810 that attracts one's interest today as he reads the specifications. They have long since lost their value or usefulness. Of course it is interesting to note that FULTON required two firemen who would "also act as engineers to keep the engine in order," and "two boatmen to take turns in steering." Fuel was required at the rate of "1½ cords of wood for 12 or 13 hours," while "ware tare and repairs" came in for substantial consideration.

But the significant item in the estimate, to one who has followed the trend of science in industry, is the fact

that FULTON had a clear appreciation of the value of trained men; for in commenting on the two firemen, he wrote, "they must be engaged for the year, as such men cannot be turned away in the winter and got in the spring." Chemists will warm to FULTON'S sentiments and wish for more of his type in industry. This is particularly true of those who, in the past year, have been "turned away in the winter" of business adversity without even the certainty of seasonal employment "in the spring" of a business revival.

Punishment for The Innocent

ON November 6 the prohibition authorities at Washington issued a new ruling in regard to alcohol for rubbing purposes. Heretofore one of the principal denaturants for rubbing alcohols has been diethylphthalate. This is practically odorless, is a solvent for essential oils and makes alcohol completely unpotable. No one would want to drink it after his first "gulp." The new ruling which goes into effect December 6 requires that besides this "the denaturer shall add to each 100 gallons of the two specified formulas (39-A and 39-B), as now authorized, three-eighths of a gallon of approved benzol of the quality specified."

Now, benzol is not odorless; it has a definite and unpleasant smell, and is a poison recorded as the cause of many deaths. Of course three-eighths of one per cent is very little, but some persons are remarkably sensitive to it. In our issue for September 20 we published an article on benzol poisoning, its occurrence and prevention. The author said that benzol may be absorbed through the skin, but he doubted if this mode of entry presents a serious hazard in industry. This referred to benzol by itself. The mixture of benzol and alcohol, however, is more volatile than either of the two, and the solution will penetrate when benzol alone will not.

After diligent inquiry among the best authorities the only excuse we can get for the use of benzol in alcohol for this purpose is that it "probably" would not have a toxic effect in three-eighths of one per cent dilution. But this is far from a guaranty. Chemists familiar with the operation of tar distilleries tell us that mere contact with benzol frequently produces eruptions like boils on the skin. Dr. ALICE HAMILTON reported in 1916 that, from inhalation of the fumes alone, fourteen new cases of acute poisoning and seven deaths occurred. Here is a typical example of the effect on one who is sensitive: A benzol kettle had been empty 24 hours, was then washed out twice with steam and permitted to stand filled with water over night. As a workman went into the kettle a strong stream of air was blown through it. Nevertheless he was overcome by the fumes. He was rescued, but one of his fellow workmen who merely assisted at the rescue was also overcome, and died within 10 minutes. Not only are persons supersensitive to this poison but those in bad health have also been observed to be especially susceptible to its dangers. There are plenty of instances of a similar nature. Benzol poisoning is a serious industrial hazard.

All nurses are trained to give patients an alcohol bath, especially in cases of fever. Denatured with diethylphthalate it has been tried and found acceptable. But to add benzol with all its hazards to this universal solvent, when its potency is increased by such a solution, and to threaten the sick and afflicted with its poisonous consequences, seems to us clear beyond the province of the prohibition authorities.

Home Tanning and The Leather Industry

WITHIN recent years the Department of Agriculture has received more than 20,000 inquiries regarding methods of home tanning. The reason for these requests, which often arrive at the rate of twenty-five to fifty a day, is not difficult to find. The disposal of a single hide or a few hides by a farmer or country butcher presents a marketing problem which often attracts more attention than other similar instances because of the opportunity for direct observation of the spread between the prices of raw material and finished product. Thus a farmer may have a single hide which he considers of excellent quality and yet be unable to dispose of it except to a junk dealer, from whom he may receive $1. About the time of this transaction he may have occasion to buy some leather and find he must pay anywhere from 90 cents to $1.50 per pound at retail. Small wonder that his first thought is to do his own tanning!

This feeling will continue as long as the farmer fails to understand thoroughly the factors that make the situation possible. As the total domestic supply of hides and skins falls short of the demand, it would seem as though there should be no trouble in marketing country hides, which constitute from 20 to 50 per cent of domestic production according to kind. But all too frequently these hides have been taken off in a careless manner and improperly cured so that they are naturally worth much less to the tanner than packer hides which have been removed by experts, thoroughly cured and carefully graded. The tanner's efforts are attended with enough difficulties even when working with uniform raw materials. There is little excuse for the farmer's failure to understand these points, for the whole subject of skinning, curing and marketing has been thoroughly covered by the Department of Agriculture in Farmers' Bulletin 1055, which may be had for the asking. As for the possibility of reducing the price spread between country and packer hides, the essential requirements have been summed up in a recent bulletin of the National Leather and Shoe Finders' Association as follows: "Unless farm organizations, working with the Department of Agriculture, can develop a plan by which country slaughter can be done by experts, sorted by experts and marketed from central points in carload lots, it will be otherwise impossible for country hides to be marketed in competition with packer hides."

Another point which the average farmer fails to appreciate is the increase in value during the conversion of the hide into leather. In this connection it seems probable that the circular on "Home Tanning" which has been prepared by the Department of Agriculture in response to the demand previously noted will prove of real value. At first sight it would seem that a pamphlet containing such information would tend toward the establishment of thousands of miniature tanneries which would be highly undesirable from an economic standpoint, even though the competition might not be felt by the tanning industry as a whole. Indeed, the bulletin points out alternatives which under normal conditions should prove more advantageous than attempting to tan one or two hides. But it seems more likely that the farmer who has the patience to follow through the entire process will gain an understanding of the tanner's problems which could be obtained in no other way—an understanding that will go far toward eliminating the present feeling of dissatisfaction.

Readers' Views and Comments

Why Not Get Away From Traditions?

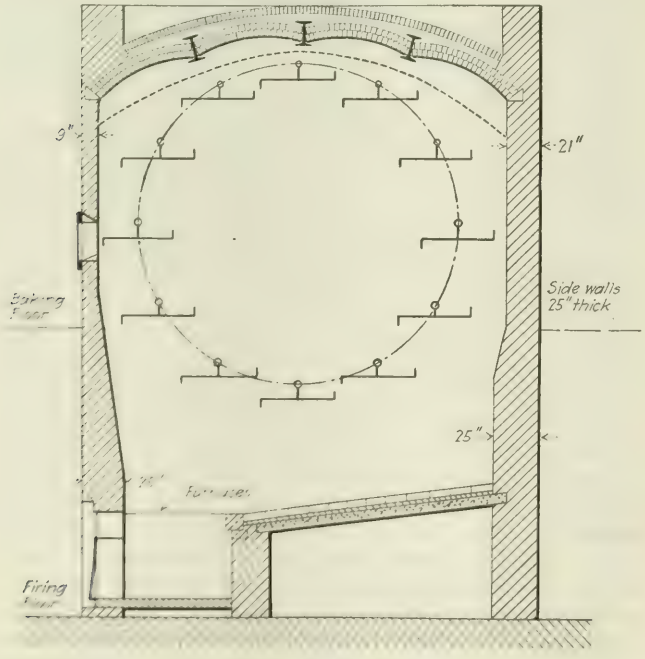
To the Editor of Chemical & Metallurgical Engineering

SIR:—The failure of one industry to avail itself of the technology of another is puzzling to engineers whose practice carries them into several fields of industry. This is explainable by conditions that lead to a state of "inbred talent" and which produce a mental state that does not permit of receiving impressions from without. There has grown a condition of self-satisfaction, or of mental inertia, that persists until the force of competition moves the management to a change of practice.

Many a business is retarded by the fact that a piece of equipment *works*. It has been developed by a process of addition and subtraction, or, as some one has said, "by guess and by gosh," until a fair degree of success has been attained; then the inbred talent rests and beholds this *ne plus ultra*, and refuses to progress further.

Sometimes, however, the check to development is given by the operator who, because the apparatus is successful from his point of view, does not wish to "experiment" and adopts a let-the-other-fellow-do-the-experimenting attitude, in spite of the fact that the "experiment" is not an experiment at all, but only the adaptation of the successful practice of another industry.

While we occasionally see an apparatus or a structure that is barely standing up, the trend is in the opposite direction, sometimes because of the lack of design data, but much oftener because of inability to design. The result is a job that costs much more than it should because the "designer" worked after a fashion that is called "playing safe." The subjects of heat transfer and thermodynamics are somewhat involved and to some people extremely abstruse, so that when called upon to produce a design there is a temptation to "play safe" and the product is a monstrosity.



SECTION OF OVEN

The figure shows a section of a reel oven such as used by the bakers of crackers, cookies and the like. The front wall is 9 in. and 25 in. thick; the back wall 21 in. and 25 in. thick, and the side walls 25 in. thick. The roof is formed by four arches sprung between steel I-beams and the front and rear walls. The top of these arches is covered with ashes, asbestos and a layer of brick. Two furnaces serve the oven; this to get a uniform distribution of the heat across the oven.

Being struck by the thickness of the walls and noting that they had no particular structural significance, I concluded that their principal function was the conservation of heat. Being desirous of reducing the weight (because these ovens would be installed in the upper stories of an old building, necessitating a new and heavy supporting structure), I suggested that a course or two of insulating brick be used, thereby permitting thinner walls and a consequent great reduction of weight. The representative of the manufacturer then assured me that the thick walls were not for the purpose of heat conservation but for heat storage (regeneration). The heat-regenerative value of thick walls, heated on one side only (not checkerwork) at a temperature of less than 600 deg. F., must be slight; and were this the main function of the brickwork, the thickness need be no greater than a single course.

The four arches in the roof next attracted my attention. I wondered why a single arch (as indicated in the figure by the dotted line), which would be cheaper to construct and also of greater stability, would not serve better than the series of arches shown. I was informed that the roof with four arches gave better baking results, which was apparently attributable to the heat stored in the volume of hot gases occupying the approximately triangular space bounded by the front (and back) wall, the adjacent arch and the circle described by the shelves of the reel. A calculation showed that the gases occupying the entire volume of the oven, in cooling 100 deg. F., would give up the heat equivalent of less than a half pound of coke. The oven described bears evidence of having been designed by bricklayers who have had experience in building boiler settings. The wall thickness, however, is even greater than is the average practice in boiler setting—and the boiler settings carry much higher temperatures.

The processes involved in the foregoing are well known to engineers familiar with the development of industries. An apparatus or process with a nebulous beginning is developed by a process of evolution to a point where progress seems to stop. This is the *ne plus ultra*. Any suggestion that an engineer or chemist be employed with a view to improvement would be met with scorn. Has not the apparatus (or process) been improved from year to year, by men trained in that particular work? What chance has an outsider, unfamiliar with the industry, to improve on the practice of experts?

Instances of "outsiders" improving the practice of "experts" are too numerous to be set aside as "flukes."

There must be a psychological explanation. Occasionally the operators of long experience are so steeped in the dogmas and superstitions of the business that they are blind to new principles or methods when they present themselves. The "outsider" will often come with a fund of experience gathered from other and somewhat similar lines of endeavor, and see at a glance opportunities for improvement.

About a dozen years ago I paid my first visit to a cement plant. One of the things I observed was a building over the full length of a number of rotary kilns. I asked the engineer responsible for the design, why the building was made to house the entire length of the kilns. His answer was, "To protect the kilns, of course." "But," I said, "the building is covered with corrugated steel sheets less than $\frac{3}{32}$ in. thick, while the kiln shells are $\frac{7}{8}$ in. thick—a case of the weaker protecting the stronger." "Well," said he, "they all do it."

C. O. SANDSTROM.

Kansas City, Mo.

Appreciation of the Engineer

To the Editor of Chemical & Metallurgical Engineering

SIR:—This appreciation of the engineer, from an editorial in the November *Current Opinion*, deserves wide circulation for its clear exposition of the engineer's position in, and duty to, organized society.

Cornell, Wis. ALLEN ABRAMS.

The Engineer

What the world needs is engineering. What has impeded the progress of the world has been its theorists, metaphysicians, philosophers, theologians and other speculators and hair-splitters.

An engineer is a man who takes a force and finds out how to work it that he may do some good to the race. This is much more to the point than speculating where the force came from, what is its nature and where it is going to.

We need the engineer in politics. The Socialist and every other kind of an ist are merely dealing in riddles. An engineer deals with facts. Instead of constructing some fine-spun theory about government, he would take people as they are and the laws of nature and of business economics as they are and try to work out something from them that would do good to humanity.

We need the engineer in religion. Religion deals with moral force. It is vastly more important to set this moral force to work, to learn its laws and to operate it for the communal good than it is to find out where it came from.

We need the engineer in the schoolroom. Instead of puzzling with theories of education, we should take the child as he is and try to make something out of him.

We need the engineer in the business world. Whenever a man begins to talk about capitalism or labor you may know he is up in the clouds. Really there is no such thing as capitalism nor as labor. These are artificial abstractions—mere counters to argue with. The real things are human work and human welfare. Work is the energy of living people and capital is the stored energy from dead people.

And there is but one problem, and that is how to manage these two forces of energy in a way to produce the most human welfare.

Some day we are going to kick the speechmakers, flag-wavers and phrase-makers out of our legislative bodies and elect engineers who will address themselves to the problem of running the country.

And some day our schools and churches will likewise be put into the hands of practical engineers who shall produce results.

EDITOR'S NOTE:—We agree with our correspondent that this is an exceptional appreciation of the engineer from an unexpected source. There are some conspicuous examples of engineers filling the needs to which the editor of *Current Opinion* refers. In politics, or rather in public life, we have Mr. Hoover, Secretary of Commerce, and Mr. Caetani, lately appointed Ambassador from Italy. In religion we recall no engineers who are following that vocation, although recently Dr. Steinmetz was a distinguished lay-preacher in a series of religious talks by laymen at Schenectady. In the schoolroom examples are more numerous, as they are also in the business world. The ability to achieve results seems to be the quality that attracts the public to these men.

Tests on Bearing Metals

To the Editor of Chemical & Metallurgical Engineering

SIR:—"Tests on High-Tin Bearing Metals," by P. W. Priestley, in your issue of Nov. 8 has reopened a very interesting subject.

Bearing alloys have received a great deal of attention by many investigators, but the technique of "testing" has not been standardized, because too many factors (only partly metallurgical) enter into such investigations. Lacking a well-established basis of comparison for any product of the metallurgical industry, we shall always find a large number of producers that make grossly exaggerated claims for their "secret compounds." Unfortunately, this patent medicine situation has existed for many years in alloys for bearings, solders and other specific purposes.

Bearing alloys have so far eluded definite testing methods because great difficulties surround this problem. The "efficiency" of bearing metals is not solely a question of metallurgy, but is also one of mechanical engineering, of physical chemistry and of lubrication. The testing of bearing metals is undoubtedly the most difficult problem in the art, being equaled only by the problem of determining the cutting efficiency of tool steels.

In order to investigate systematically a series of bearing alloys, quite a number of laboratory tests must be carried out, to detect any basically faulty materials. Such preliminaries often eliminate the necessity of further commercial tests. Among the laboratory tests are:

1. *Microstructure of the Alloys.* This is required to determine, first of all, whether the basic requirements of a bearing alloy (a soft background with imbedded hard grains) are met. The "micro-character" and tentative scale of micro-hardness developed by the research sub-committee of the American Society of Mechanical Engineers will be found very useful. It will be quite important, I believe, to insure that the hardest grains in the bearing alloy are not harder than the shaft, so that the latter is not scored if the lubrication should fail.

2. *Elastic Limit Under Compression.* The Martens mirror extensometer can often be replaced by gradually compressing a cube of the alloy. One side of this specimen is prepared for microscopic investigation; it is continually observed, and the load determined at which the microstructure begins to change. However, the only certain method for determining the elastic limit which is of practical importance with bearing alloys is to determine the load at which a definite permanent set, say 0.2 per cent, takes place.

3. *Compressive Strength.* This test is usually carried out by compressing cylindrical specimens of the alloy until cracks appear at the surface of the specimen. This method suffers from a similar error as our standard tensile tests: the result is calculated on the basis of a cross-section undergoing progressive changes. The only

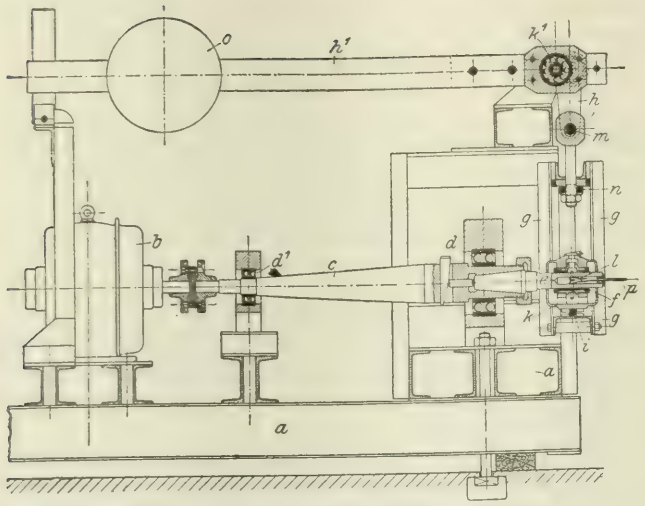


FIG. 1—KAMMERER'S TEST BENCH FOR JOURNAL BEARINGS

correct method of carrying out such tests is to establish curves in which the progressive increase of diameter of the specimen is shown against the increase of load.

4. *The Melting Point of the Alloy Should Be as High as Possible.* New lead-barium and lead-calcium alloys have a melting point of about 290 deg. C. (554 deg. F.). Since the lubricating material will give off penetrating odors before these temperatures are reached, an alarm signal is given before the bearings fail. If bearings are air-cooled as in moving railroad cars, such high temperatures cannot be reached; it will be of interest to note that such alloys permitted the German State Railways to run its trains successfully during the war without any lubricant whatever.

5. *Hardness.* While a knowledge of micro-hardness is very useful to determine the correct microstructure, the Brinell test (500 kg. load) will yield valuable information as to whether the alloy is in general suitable for its purpose. The Brinell test cannot, however, serve as a criterion of the comparative quality of such bearing alloys. Its largest value is to be found in controlling one definite alloy—each possesses highest efficiency at one certain Brinell hardness, and the engineer is thus in a position to determine conveniently whether a particular alloy is in its prime condition. The Brinell machine will also permit one to determine a figure which has considerable value in bearing alloys: the relation between the hardness unit, obtained by increasing the load at a determined rate to 500 kg. and then releasing immediately, and the hardness unit obtained on the same alloy by exposing a specimen to the maximum load for a period of 3 minutes. The figures thus obtained both at room and at elevated temperatures give information on the plasticity of the alloy, a property which largely affects its general efficiency.

Bearing alloys can best be investigated on a "test bench" similar to those used for automobile engines. According to my experience, the simplest and most useful is the one designed by Professor Kammerer at the Institute of Technology of Charlottenburg. Its construction is illustrated in Fig. 1. Shaft *c* runs in ball bearings *d* and *d'*, and is driven by a variable-speed motor *b*. The bearing *f* under test is pressed upward against the journal *e* by a lever system; the load can be adjusted by weights sliding on the lever arm h^1. The machine and lever system is constructed with suspensions of spherical joints in such manner that the pressure of journal against bearing surface is perfectly uniform. Thermometer *p* measures the temperature of the bearing during the test. The main factors of such a test are the pressure between shaft and bearing, the surface of bearing and the bearing temperature (which is influenced to a considerable extent by the former two and the nature of the lubricant). Tests are run systematically in series; after the bearings are "run in" at a definite load, the speed is increased from lowest to highest limit and the maximum temperature reached is determined in definite steps, say at 300, 500, 1,000 and 1,200 r.p.m. After the temperature no longer changes with time, the speed is again reduced to a minimum but the load increased by a definite amount. Then the speed is again increased by steps, and so to failure.

Such a test bench can be provided with simple attachments to reproduce adverse conditions often encountered in practice. For instance, an eccentric shaft may bear against the load lever, producing periodic pressure releases on the test bearing. Or a cam arrangement might be installed producing impact forces.

The importance of viscosity of a particular lubricant has been overrated. The usefulness of a lubricant depends upon the forces of adhesion to the metal and not upon the cohesion of the oil molecules to one another—i.e., its viscosity. Bare mention of this important point shows that the testing of bearing metals is not a purely metallurgical and mechanical problem.

At any rate it should not be difficult to standardize commercial tests for bearing metals by means of a simple test bench that anybody can operate and that is quite definite in its indications.

New York City. HERMAN A. HOLZ.

Road Tests for Comparing Fuels

For the past 2 months, in conjunction with the Society of Automotive Engineers, American Petroleum Institute and the National Automobile Chamber of Commerce, the Bureau of Standards has been conducting a co-operative fuel research program.

The purpose of this work, according to a statement recently made by Major R. E. Carlson of the Bureau of Standards, is to obtain data which can be used as a basis for estimating the effect of change in gasoline volatility on the average fuel consumption of cars now in service throughout the country. The effect of these fuels on crankcase dilution, change in viscosity of the lubricating oil and ease of starting of the motor will also be investigated.

This co-operative fuel research program is still in progress at the Bureau of Standards and the form in which the results obtained will be published is a matter for final decision by the bureau and the three societies.

The personnel employed in these tests consists of representatives of the oil and automotive industries who have been loaned to the bureau and two representatives from the bureau to direct the work. In a problem of this sort where the results are of such far-reaching importance both to the petroleum and the automotive industries, it is of vital importance that the results be accepted at their true value when the program is completed. It is believed that the representation of both industries throughout the entire program of tests will greatly facilitate this acceptance of results because at all times both industries were entirely familiar with what is being done and how it is being done. Besides, these tests have been conducted by an impartial agency.

The Twelve-Hour Shift

A Discussion of the Present Status of This Great Problem and a Review of the Report of the Federated American Engineering Societies on the Twelve-Hour Shift in American Industry

By Charles Wadsworth, 3d

PERHAPS at the very beginning we should adopt a text which shall serve as the underlying theme of this discussion. It is from the introduction to the Federated American Engineering Society's report on this subject, which will be reviewed during the latter part of this article: "The desirability of abandoning the two-shift system lies not in its extent in industry but in the fact that the 12-hour day is too long when measured by twentieth-century ideas as to the proper conduct of industry. Economic considerations demanding a length of day which will give maximum production are influenced today by humanitarian considerations."

Thus we are shown to believe that the 12-hour shift should go. This article will deal with the reasons for the existence of the 12-hour shift, with the reasons why it has persisted in the face of great pressure, and with the two questions, so ably discussed in the report above referred to, the extent of the 12-hour shift and the remedies or substitutes which have been used to replace it.

There are in this problem three points of view which we should establish before we can understand the puzzle: The point of view of the public, that of the management or employer and that of the worker.

The Public's Opinion

There is still an unintelligent minority of the public who call to mind the concept of the farmer, with 16 hours of uninterrupted (?) work. They remark with conviction that the industrial worker is being babied anyway and that 12 hours is shorter than 16. Not a few employers feel that the industrial worker is being babied, but there will be relatively few whose views would coincide with that just mentioned.

A decreasing percentage of the public is uninformed on the 12-hour day. This is partly due to the strong artisan unions which have been universally successful in eliminating it from their trades; partly to progressive manufacturers who have successfully installed a shorter shift; but mostly, no doubt, to the widespread press publicity which is always given to the U. S. Steel Corporation and its decisions, changes and problems.

The vast majority of the public is passively opposed to the 12-hour working day. They wonder at its persistence and even professional investigators and reformers are puzzled. Everything seems to point to its speedy elimination and yet here it is. Why?

Part of the answer can be found in the employers' point of view and the rest of it in the laborers' attitude. These we shall try to make as graphic as possible.

The Employer Thinks?

The manufacturer (or employer) who uses the two-shift (12-hour day) system has an attitude which varies between rather narrow limits. We can take as a basis for his attitude the background that the 12-hour day exists and *status quo* has great inertia. In his industry there probably has been until recently, and perhaps even yet, little sentiment against the 12-hour day. Grandfather or father (or if not his ancestors at least his predecessors) used the two-shift system and nothing has called his attention to the necessity of changing it —neither public opinion, nor labor demand, nor yet law. So there is an understandable *laissez faire* background for his attitude. With such a base the attitude of the individual employer will be seasoned by the combination of a number of ingredients. There are many to whom progressive ideas are infrequent. Again, a larger number believe that the 8-hour day is much more expensive and any humanitarian impulse has been either stillborn or strangled by commercial instinct. Of course this is no crime, but it is not progressive, and the question of whether the 8-hour day is more expensive is at least debatable. There are others who bow to the demand of labor for a 12-hour day! Yes, that's a fact, though it seems strange. Possibly there are other ingredients in the developed attitude of the individual employer, but these are the principal ones. So by properly balancing them we can construct a given employer's thought on the 12-hour day where it still persists.

The technical man in industry reflects the attitude of the employer. He must if he wants to butter his bread with salary from that firm. We heard of one man who objected strenuously to a labor wage reduction. "The men couldn't live on the reduced wage. It was unfair." His colleagues looked on the protest as foolish and with a kind of pained tolerance. His employer wished him farewell with the next pay check. So with enough exceptions to permit a healthy generalization the technical man's attitude on labor questions is necessarily a blind following of employer's views.

But Why Does the Laborer Stand for It?

Remember first that those workers who are still on a 12-hour shift basis are wholly unorganized and then reflect on these three stories which perhaps bring out the laborer's attitude better than an abstract description.

It was still night and the glare of the arcs was the only light on a rather wide street except for a few cheap restaurants. Every half minute a first cousin of the original Toonerville trolley bumped and rocked down the track toward the plant, filled to overflowing. One knew there was a plant there, for a bright bessemer flame said so. There were several. On the sidewalks a silent army plodded rather than walked, hundreds of them, thousands actually. There was some talk, sometimes a shouted sally and a retort. Then we turned off from the crowd to an interurban station which carried us to a nearby plant.

Back again at night and the interurban brought us in just as this same crowd was coming home. And if these plodded in the morning, they dragged now and there were no shouted sallies and no talk. Just a procession of tired out animals seeking only rest, food and those pleasures which satisfy without effort and which help to drown the dreary drudgery.

Such was the background for the answers that came to our question during some months of contact, "Why do you stick on this 12-hour shift work?" Three men can give answers which are typical of a vast majority.

Bill Brown was a Yankee who referred to all foreigners as "hunkies." All "hunkies" were either "pretty good hunkies" or "——— — ———." He would have been over 6 ft. if he had not stooped. If he was on night shift, he got shaved Saturday afternoon before he went on to the 24-hour shift. (Twenty-four hours were necessary in order that each shift would work one week at night and one week in the daytime.) If he was on day shift, he got shaved Saturday evening after he came off for his 24-hour rest. Bill had a son doing "railroadin'" and a rather numerous family. He handed in a tax return of over $2,100 in 1920. It was under $1,500 in 1921, for the same work, 12 hours a day nearly every day in the year. "Oh," said Bill, "I get enuff to live on and I know the game. It's a hell uv a life, but what kin yuh do? No, I couldn't afford to work only 8 hours. ——— — ———. Somebody'd haf tuh quit eatin'." You can translate it if you so desire. It means more to us as Bill said it.

Then there was Roman Bdfghijklmnpqr (it doesn't matter what his last name was) a bright-looking Slav of 25. A Ukrainian from farmer-peasant stock whose industry had commended him to his bosses and he was already a foreman. "Oh yes, I stay this country. Most my countrymen they come make money, go back. They buy farm. They live with nothing while they here. No, this factory job no good. Make you sick, but it pay good. You work like hell 10, 15 years—then you quit."

And finally there is Joe—"Boiler" Joe to distinguish him from a couple of other Joes in his gang. He has been in America 12 years and he knows three English phrases well enough to say them. Two of them are unprintable, the other is "No good." From somewhere in Russia where the Nordic strain is slender, stupid and dull, understanding English enough to grunt and nod when he is told to do something and to nod assent when someone answers for him. Already he has gone back with as many thousands as there were years of service. He had several times refused to work at all rather than go on an 8-hour job. Twelve hours or nothing! Thinking no more of America than an exploiter would think of the place where oil fields happen to be. The real reason why Americanization campaigns are stillborn and educational campaigns fail in some districts. America is a place to make money in and then return to God's country. These three men are common types, and it is not a far disproportion to assume that the 12-hour shift problem is two-thirds a foreign problem.

Present Status of the Puzzle

So we have the public largely passively opposed to the 12-hour day, but without a sufficiently active sentiment to have anything crystallize; the manufacturer inactive principally because of the inertia of existing conditions, hesitant further because of the fear of greatly increased costs; and finally the laborer completely lacking organization, largely of foreign origin, regarding his work has a necessary penance for either a comfortable old age or for the "crime" of having to support a family, and for the most part either unable to find work at shorter hours or unwilling to consider it. Therefore the 12-hour day persists and to anyone who has lived in a 12-hour shift community the institution looms as a menace to civilization, for civilized living is impossible under it.

How Extensive Is This Menace

The report of the Federated Amercan Engineering Societies discusses the extent of the 12-hour shift in American industries and some of the substitutes which have been tried in place of it. The study was made possible by a grant from the Cabot Fund and the work with which we are concerned was carried out by Horace B. Drury.

Confined to Continuous Industries

Mr. Drury points out that the 12-hour shift is confined almost exclusively to the continuous process industries and these in general belong to one of three types. The first type consists of those industries which employ high temperatures and cannot afford to let a large bulk of equipment cool off only to be heated up again the next day even if this were possible. There are of course many industries in which it takes days to heat up the equipment to a point where production is possible. These are called the heat process industries. To the second type belong those which, because of chemical reactions, cannot be stopped and started again, such as chamber sulphuric acid, soap saponification and hundreds of others. These are the chemical process industries. Finally there are industries in which the investment in equipment is extensive and the overhead charges would be prohibitively high per unit produced, if the work were not continued throughout 24 hours.

All of the men in these industries are not on 12-hour shift, of course, and an accurate estimate is impossible. Mr. Drury says that from 5 to 10 per cent of American industry is continuous process work and that from five hundred thousand to a million men are engaged in it. Those depending on the wages of these men will number close to two million persons. Finally, as nearly as can be estimated, about 300,000 wage earners work on the 12-hour shift. Thus the problem from its mere extent might not merit the attention it is receiving. But it has been justly condemned, and this condemnation has been increasing so extensively that it is not un-

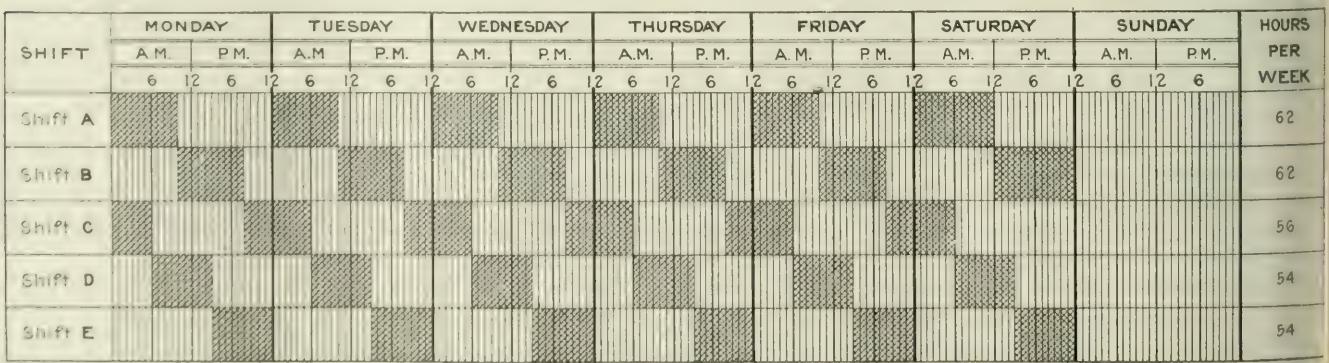

FIG. 1—FIVE-SHIFT SCHEME WITH 9- AND 10-HOUR SHIFTS

likely to take the form of legislative action. What, then, are the industries affected and what remedies have proved successful?

Method Used in Obtaining Data

Unfortunately there were practically no data available on this subject and it was necessary to accumulate the information by exhaustive field work. Mr. Drury's investigation could not of course be complete, so he has made it representative. He has investigated forty-four different industrial centers, among which are New York, Philadelphia, Chicago, Pittsburgh, Cleveland, Buffalo, Akron, Youngstown, Gary, Birmingham, St. Louis, Kansas City and Denver. In addition such localities as the southern New Jersey glass plants and the pottery plants near East Liverpool, Ohio, were also studied. He has grouped the continuous industries into four main groups indicated in the table below. We are of course primarily interested in groups I and II.

Group I.	Iron and steel	Group III.	Paper
	Non-ferrous metals		Flour
	Glass		Rubber
	Cement		Breakfast foods
	Lime		Autos
	Brick		Textiles
	Pottery		Mines
Group II.	Heavy chemicals	Group IV.	Power
	Fertilizers		Gas
	Explosives		Water
	Dyes		Ice
	Industrial alcohol		Shipping
	Wood distillation		Railroad
	Refined corn products		Street railways
	Soap		Telegraph
	Glue		Telephone
	Drugs		Mails and express
	Sugar		Policemen
	Electrochemicals		Firemen
	Petroleum		Watchmen
	Salt		
	Cottonseed oil and other oils		

How Much Will the Three-Shift System Increase Labor Cost?

Already the estimated extent of the 12-hour shift has been given. There are nine other questions dealing largely with the change from the two-shift system to some other operation plan. Therefore a brief discussion of these alternatives is appropriate. Perhaps the most obvious and familiar substitute is three 8-hour shifts. The cautious manufacturer is apt to conclude that this will increase the payroll by 50 per cent, and right here lies the greatest problem in eliminating the 12-hour shift. If the manufacturer wants to keep his costs the same, he naturally infers that he must keep labor costs where they are. In this case the wage earner will receive just two-thirds of his former daily wage. No such conclusion is warranted. In a very few instances, one a sulphuric acid plant, it has been found that the number of shift workers was increased just 50 per cent with no increase in production. Yet in another plant producing the same material the increased production attributed by the manager entirely to a reduction in working hours from 12 to 8 per shift was startlingly large.

It is therefore necessary to be very cautious about making dogmatic deductions with regard to this change. Each plant is an individual case. Few generalizations can be made even within a given industry. So much depends on the kind of equipment, the type of process, the caliber of management, the attitude of the laborer, the progressiveness of the industry and the plant, the proportion of labor cost to total cost, etc.

Suppose we have a plant manufacturing a product where the labor cost is 25 per cent of the total cost. In most chemical industries this proportion is higher than actually exists, for the labor cost is often below 10 per cent and seldom above 20 per cent. If we increased labor cost 50 per cent, it would increase the cost of the product only 12 per cent. That, then, is a kind of limiting figure for changing from 12-hour to 8-hour shift. It assumes that the weekly wages would be kept exactly the same, the hourly rate would then be 50 per cent more and the total number of laborers increased by one whole shift.

Some Factors Which Would Diminish the Three-Shift Increment on Labor Cost

In the first place, there are few works in which all the men would be on 12-hour shifts. Hence the increment would naturally be decreased in proportion to the number of men on shorter hours. Again it is a pretty safe generalization to claim that in a rearrangement of tasks which would accompany a fundamental change of this kind, a decided cut could be made in the number of workers per shift. In one plant I recall a large cut in the personnel of a shift by having each shift stay 9 hours and in that extra hour complete all the tasks incidental to actual operation. Therefore again the increment of cost necessary to effect a change from 12- to 8-hour shift would decrease, still maintaining the same weekly standard of wages.

In a sufficient number of cases to justify its inclusion the change from two shifts to three has focused the attention of the management on equipment and kindred problems, and a pronounced increase in plant efficiency has resulted. Perhaps the benefit cannot be solely attributed to the three-shift change, but its inception was undoubtedly due to the study made necessary by the three-shift change.

In many industries labor will do more work per hour in an 8-hour shift than in the longer session. This is, of course, much less true of the continuous process industries than of those in which a more skilled labor is necessary and a higher type of manual efficiency. Yet the sulphuric acid plant referred to above is only one example of many in which this result has been accomplished and there is no doubt that industrial accidents, absenteeism and labor turnover have all been favorably affected by the three-shift program.

Each of these points has been advanced to indicate the certainty that in changing from a two- to a three-shift program the labor costs would not be increased greatly even if the weekly earnings of the shift workers were kept to the figure obtained in 12-hour work. With slight reductions in total wages (but a higher hourly rate) and a slightly higher labor charge, the change can probably be effected in every industrial plant that is well managed.

The message which the report brings to the manufacturers is: "Don't shy at three-shift operation; investigate it. If it does cost more, you may be more than repaid by diminishing accidents, labor turnover and absenteeism. And it may not cost you anything." Furthermore, such a message is very timely when the immigration and emigation statistics are studied—a net loss in 1921 of 67,000 laborers (continuous process labor)! If that continues will it pay to diminish labor

turnover? It will not only pay, it will be absolutely essential.

Other Substitutes for the 12-Hour Day

In addition to the three 8-hour shifts which have been discussed at such great length, there are other substitutes which have been used, as follows: (*a*) Cessation of work allowing two 10- or 11-hour days. (*b*) Nominal 12-hour day, but work completed in 10 to 11 hours. (*c*) Three overlapping 9-hour shifts. (*d*) Nine- and 10-hour shifts on a five-shift scheme.

This last alternative is so interesting that we have reproduced the diagram which is now used by Procter & Gamble for their shift labor. (See Fig. 1.) It is self-explanatory. You will note that there are always two shifts at work.

Some Further Conclusions Which Are Made in the Report

There are other conclusions which Mr. Drury finds closely related to those already discussed. He has found no technical difficulties in the way of changing from two- to three-shift operation. This is to be expected and could have been stated *a priori* by those who are acquainted with shift work. It was wise to include it in the report, however.

Mr. Drury found a general favoring of the three-shift plan and a negligible number of firms returning to a two-shift system after the three-shift plant had been tried. Another gratifying conclusion is that the daily wage earnings tend to equalize those of the two-shift system by an increase in the wage rate. You can argue at greater length than we did earlier in this report that wages won't have to be reduced, but an ounce or two of proof such as the above is worth much more.

Finally it is also gratifying to learn that the leisure time of the employee is well used. This is not necessarily to be expected from the type engaged in shift work, and many a manufacturer has remarked that the workers would drink away their spare time, advancing that as one reason why it would be foolish to change to three-shift work. It now becomes a boomerang and an added reason for adopting the shorter day.

What Is Meant by Co-operation of the Worker

The summary concludes with a word of caution: Do not change without careful preparation. A sudden change not preplanned and which has not enlisted the co-operation of the workers is almost certain to result in lower production. And this is a word of great wisdom. It is a point which is worth enlarging, for those unfamiliar with operating work will completely miss the significance of the term "co-operation of the worker."

There was once a bright and ambitious chemical engineer who was assigned to the task of studying and revising a process. It was a batch process that required careful furnacing to an end point and subsequent leaching. If the end point was not reached, the material cooled to a hard, impenetrable mass. If it overburned, considerable destruction of product was involved. The chemical engineer wished to make some changes in operation which were logical and scientifically sound, but somehow or other they did not work. The yield did not improve. In fact it fell off. He was worried and went to the superintendent. The superintendent listened, waited a week spending an imperceptibly longer time in the department each day and assigning the chemical engineer to other work. Then he spent an hour or more a day talking with the furnace men not about the work or the low yields (which the furnace men didn't know). Then one day they told him how they had fooled the chemical engineer. He had come in and changed the process so that it meant more coal to haul in and shovel. It was no cinch to stand up in front of that roaring blast and shovel in more coal. But they had fixed him, doctored the coal weights and run a hotter fire by building up from the start instead of burning gradually. So the particles were glazed and no additional action had been possible. It had not been a poor piece of technical work, but the "co-operation of the worker" had not been enlisted.

So the co-operation of the worker would have to be enlisted in this change to a three-shift plan. If it had been applied to the above process and the furnace men had been unsympathetic, you would have had every charge glazed or overburned. The reason would have been that the previous or the subsequent shift ruined the charges and "you can't get the furnace in shape on a short shift."

Mr. Drury struck a keynote when he mentioned the co-operation of the worker, and that is why earlier in this discussion so much emphasis was placed on not reducing the daily wages, for this is an important factor in labor co-operation. Even then there will be trouble in some organizations, especially where you have foreign elements. Their argument will be, "If you can pay the higher rate per hour, then we'll take it and work 12 hours too." They are horses for punishment! This subject of "labor co-operation" would be extremely appropriate for detailed investigation. It is the crux of success or failure in the two- to three-shift change.

Too Optimistic Claims Must Be Avoided for the Shorter Shift

There is one other point of caution that must be urged. In many industries careful and thoughtful attention on the part of the management would increase process efficiency greatly. This careful and thoughtful attention is necessary when the change from two- to three-shift operation is made. Thus many improvements may be attributed to the change in working hours which are actually due to the study which accompanied it. We would be the last to desire in any way to put a damper on the splendid movement toward the elimination of the 12-hour shift, and we do not wish this to be interpreted in that light. Too often, however, a movement defeats itself by claiming too much and failing of accomplishment. We know organizations that still retain the 12-hour shift and which would not be benefited by the change to shorter shift. They have already been vigorous in their quest for labor efficiency. To try to sell them the 8-hour shift on the basis of marked improvement shown when other firms in the same industry adopted the shorter work day would be a mistake. No management engineer could produce the goods. Hence this word of caution that we should not attribute all the gains to the change in hours!

In an appendix to this discussion is given a summary of the 12-hour day problem in some of the industries in which the readers of *Chem. & Met.* are interested. There remains only a word of commendation and approval for the exhaustive and balanced report. The Federated American Engineering Societies is to be congratulated. The contribution to knowledge is signal. The direct gain to industry and to civilization should

be permanent and immense. The report will do more toward eliminating one of the black corners, fester spots, from our civilization than all the rant and chatter of the zealous reformers combined. It is distinguished evidence that the organization is fulfilling the worthy ideal expressed in its constitution: "To further public interest wherever technical knowledge and engineering experience are involved."

Appendix to the Report on the 12-Hour Day in American Industry

Herewith is a summary of the detailed studies made in industries in which *Chem. & Met.* readers are interested:

Glass—In the average glass factory, those men operating the furnace are involved in a continuous process work and there are probably more of them on 12-hour shifts than on 8-hour shifts, but there are relatively few men actually on furnace work. If the cutters and the annealers are also on continuous work, it brings the number up to a very considerable figure. On the other hand, in many phases of the glass industry, there has never been anything but relatively short hours. Bottle blowers, window-glass manufacturers and now even plate-glass manufacturers are all on a predominantly three-shift basis. Individual members of the organization, however, still retain the two-shift status.

Cement—Better and more inclusive data exist in the cement industry than in any other industry, due to the activities of the conservation committee of the Portland Cement Association. This committee has made a very interesting comparison between the man-hours required to produce one barrel of cement in those factories on two-shift operation and in those factories on three-shift operation. The table is important and is herewith reproduced. (Table I.) The difference is pronounced and the investigator was careful to inquire whether the more progressive concerns might have gone on three shifts, leaving the less progressive on two shifts, but the conservation committee of the association believed that the difference was not due to any extraneous conditions. The present view of the association, through the chairman of its conservation committee, seems to be that a combination of two-shift and three-shift operation is at the present a little more economical than the wholly three-shift operation, but it believes that ultimately the three-shift operation will be universal.

TABLE I—COMPARATIVE LABOR EFFICIENCY OF 86 PORTLAND CEMENT PLANTS IN 1920

(Data Supplied by Committee on Conservation, Portland Cement Association)

Shift System	Number of Plants	Man-Hours to Produce One Barrel: Average of Group	Most Efficient Plant in Group	Least Efficient Plant in Group
Two-shift group	51	1.035	0.551	1.940
Three-shift group	22	.823	.466	1.540
Two-three-shift group	13	.756	.470	1.140

The hourly wage of the men as they went from two to three shifts was raised 6 or 7 cents an hour, so that they received slightly less than the 10-hour men, but only slightly less, and this increase in hourly wage has been more than wiped out by increased efficiency in the workers.

Lime—The lime industry has a smaller proportion of shift workers than the cement industry, with the result that the shift work is even less significant, only about 15 per cent of the men being involved. They are the ones that handle kilns, and in general they are on a two-shift basis, particularly in the East and the South. One plant is successfully running now on a three-shift basis, at the request of the workmen, and no increase in manning the kiln was necessary by a rearrangement of labor. Tables were given showing how this was worked out in practice.

Heavy Chemicals—There is relatively a small amount of two-shift operation in the production of heavy chemicals, and in the South this is principally on a 12-hour basis. In the North, except among smaller plants, the shift is 8 hours. In most cases the managers of heavy chemical plants express doubt as to any marked improvement in efficiency under three-shift operation. Most of them felt that there could be no increase in output, although they admitted it would have a favorable effect on accidents, inferior work, etc. The experience of one company, however, is exactly the reverse of this and production on a three-shift basis was increased markedly over the two-shift basis.

Fertilizers—In fertilizer plants the only department which has continuous work is the sulphuric acid department, and here in a plant having 100 laborers there would be only eight or nine on shift work. These are very largely on the 12-hour shift basis. It is the expressed opinion of a leader in acid production in the country that three-shift operation would be beneficial.

Explosives—Here again the number of men engaged in shift work is small and so far as is known, most of the work is carried out on a three-shift basis.

Dyes—Again, in this industry the processes are so varied that a generalization is somewhat unwise, but there are very few men on shift work and those that are on shift work usually work an average of 12 hours.

Industrial Alcohol—This commodity is manufactured in a number of plants. The largest company is entirely on a three-shift basis.

Soap—This is principally a daytime proposition in the majority of plants, except for a few men engaged in auxiliary processes. Ordinarily soap fats are boiled by day and permitted to settle by night. Some plants run on a two 12-hour shift basis when the market permits the plant to run at this capacity, but soap makers in general are against continuous operation except when it is essential.

Some companies, such as the Procter & Gamble Co., of Ivorydale, because they undertake more preliminary treatment of materials than is customary, have a larger percentage of men on shift operation. About 25 per cent of this company's employees are on continuous operation work.

Sugar—There are three branches of the sugar industry. (1) The sugar mills of the South which take Louisiana cane and manufacture white sugar from it. The majority of these mills are at the present time seasonal and work on two 12-hour shifts, with no thought of change.* (2) The refining of imported sugar by large refineries on the Atlantic, Pacific and Gulf seaboards. This type of factory employs no greater than 50 per cent of shift workers, although the whole process is practically continuous. Most of the refineries operate on two shifts, although some of the companies have tried out the three-shift operation with some success. Indeed, one of the plants of the American Sugar Refining Co. has been working for the last 4 years under a three-shift basis with excellent success. (3) Beet sugar. Here again we have a seasonal industry which does not last over 100 days and in which there is practically universal 12-hour shift work. It attracts many men year after year to this seasonal work, and in general they find it desirable. One company has, however, tried out the three-shift policy with satisfactory results, but it is the pioneer in this particular field.

Table Salt—This is an industry which requires very few men on shift work and with few exceptions the plants retain the 12-hour shift basis.

Petroleum—Together with rubber and some of the nonferrous metals, this industry has the distinction of being solidly three-shift. The Standard Oil, and all of the important independents, are on the 8-hour system. With oil drilling, of course, the situation is different; contractors are in charge and govern their own crews and in addition the excitement of work in the field results in rush work and long hours.

Cottonseed, Linseed and Other Vegetable Oils—The crushing industry presents the largest 12-hour shift problem in American industries. The operation is seasonal, although in the larger companies it has been extended to 8 or 9 months, but the shortness of the season has demanded two-shift operation and the predominance of colored help may also influence the tendency toward two-shift operation. In refining very little work is done at night time and the crews engaged in this work are relatively small.

*Editor's Note—It will be interesting to follow the effect of the use of vegetable chars on this industry. There are some of the plants now which operate continuously throughout the year and perhaps other arrangements than the 12-hour shift will come into vogue.

European Conditions as I Saw Them*

Status of the French Chemical and Metallurgical Industries, Notably Dyes, Synthetic Nitrogen, Fuel for Internal Combustion Engines, Iron and Steel—Hydro-Electric Power Development—Impressions on the General Situation in Italy and Switzerland

By J. S. Negru

BEFORE the war France had a flourishing heavy chemical industry, but was obliged to depend largely on Germany and partly on Switzerland for organic chemicals, especially dyes. The present status shows no material change. When the plants in the devastated regions shall have been fully reconstructed and put in operation, all of France's need for heavy chemicals can be met from home production, and she will even be in a position to export. With respect to the dye industry, she has made great efforts to become independent, but with no tangible success. Before the war there were in France four French dye plants, producing about 10 per cent of her requirements, although even these plants were obliged to import from Germany a large part of the necessary intermediates. In addition to these four, there were a few German-owned dye plants, but the combined production of all was not sufficient to meet domestic needs, and accordingly there was an annual import of about 2,000 tons of dyes, valued at about $1,500,000. The total yearly consumption was about 9,000 tons, valued at about $5,000,000.

French Efforts to Build Up a Domestic Dye Industry

Strenuous efforts were made during the war to build up a domestic French dye industry. It was in 1917 that the Compagnie Nationale des Matières Colorantes (National Dye Co.) was definitely established. Since then other companies have been formed, but all have had to struggle hard for existence and have been badly in need of government aid. This help has been given in some degree, but it has not been enough to insure the establishment of a self-supporting dye industry. The French have made mistakes in this industry, just as the other nations have. Primarily the construction program was far too ambitious. They put up plants of large size that could boast a capacity of 15,000 tons a year, but they found themselves without the necessary chemists, engineers, foremen and even common laborers to man them, not to speak of the difficulty of obtaining sufficient raw material to operate them. Of course this policy was wrong and bound to meet with failure. The experience has been a hard teacher, but the lesson has been learned, and in July I discovered that the industry was making a fresh start in the direction of educating and recruiting trained personnel with which to man the plants.

French Dye Industry to Get German Technical Assistance

In connection with the French dye industry, our readers will recall that when Dr. Hendrick returned from his summer in England he wrote a review of the dye situation in Great Britain and Europe as he had observed it. Particular emphasis was laid upon the Franco-German working agreement whereby the German firms were to give the French company technical assistance and information regarding the processes of manufacture and to supply German chemists to supervise work in the French dye plants. In return the French company was to limit its field of commercial activity and allow the Germans a share of the profits. I was in Belgium when news of this arrangement was published in the London *Times* for Aug. 1, and I immediately took occasion to discuss the proposal with all who might be expected to have an opinion on it. The general reaction to this prospect of Germany becoming an international partner in the dye industry of various countries was distinctly favorable; and however surprising and distasteful this view may be to Americans, I am sure that as far as Europe is concerned it has much to recommend it. The nations of the world are all desirous of establishing their own dye industries, having been impelled to take this step as a matter of national defense, if not of industrial advantage. Germany, on the other hand, has 50 years of knowledge and experience in dye manufacture. It is well recognized that this knowledge and experience are of more value than all the plants that European countries can erect at the present time, if they find themselves unable to operate them efficiently. Why, then, it is not good business for France or any other country to enter into an agreement with Germany whereby the latter will furnish the necessary knowledge, experience and supervision of manufacture in return for a share of the profits? France can thus at one stroke obtain the benefit of 50 years of experience; can begin immediately the establishment of a domestic dye industry; can train her own chemists and technicians in the necessary technique of the business, and ultimately develop at home a dye industry quite as efficient and serviceable as exists in Germany itself.

Advantages of Franco-German Dye Industry Agreement

Much has been made of the necessity for establishing a dye industry in countries other than Germany on account of the close relation of this business to chemical warfare. The industry is rightly recognized as a factor in national defense, although I feel that Germany's erstwhile advantage in this respect has now largely disappeared. And with the continued infiltration of German dye chemists into France and other countries and the gradual building up of a domestic industry and trained personnel, the German advantage is bound to diminish to a point where it will disappear altogether. No one knows better than the Germans that their original advantage lay in their knowledge and experience, more than in their plants; and accordingly it is they who recognize the waning of this advantage as the other nations develop experienced men.

*This is the sixth of a series of articles by Mr. Negru on this subject. The preceding articles appeared in the issues of Oct. 18, Oct. 25, Nov. 8, Nov. 15 and Nov. 22.

Regardless of how others may look at the problem, the French see clearly the advantage of using their present plants as practical schools under German tutorship, knowing that otherwise the industry will become more and more of a liability. This is a beginning in the international diffusion of knowledge that in my judgment will do more than solemn peace agreements to abolish chemical warfare, by putting the nations of the world on an equal footing with respect to it. This view is prevalent even among some thoughtful heads in Germany who know that it is not plants, but chemists, that really count. Plants can be erected quickly enough, but chemists cannot be made to order, at least not on short order.

Synthetic Nitrogen Industry

The synthetic nitrogen industry is absorbing the attention of the French to a degree even greater than that of her dye industry. This results from the ever-increasing need of ammonia fertilizers. Thus the French consumption of ammonium sulphate was only 127,000 tons in 1921, when more than 300,000 tons is needed. Warm debates and discussions are held as to whether France shall adopt the Haber-Bosch process in her prospective plants or whether she shall wait until Claude has solved all the problems of commercial production by his high-pressure process. The cyanamid process also has its advocates, and even the arc process is considered. The question is so important that the French Society of Civil Engineers devoted two meetings to a discussion of the problem. The four processes were presented by experts, and later the relative merits of each were discussed by chemists and engineers in the hope of reaching a well-considered decision. Messrs. Gros, Patart, Claude and Garaix presented respectively the arc, Haber-Bosch, Claude and cyanamid processes. The weight of opinion is in favor of the second and third, although no final conclusion has been reached.[17]

Fuel for Internal Combustion Engines

One of the most important problems now confronting France is the development of a new fuel for internal combustion engines. It it known that she possesses very small petroleum fields and that practically her entire requirements of gasoline have to be imported. On the other hand, France is a large producer of alcohol and a great deal of experimenting has been done to use at least a part of this material as fuel. The first practical attempts were not very encouraging, and it seemed that something would have to be done to encourage further experimenting. With this in view the Agricultural Committee of Béziers instituted a national competition, offering prizes for the best practical solution of the problem. The main requisite is that the fuel shall contain at least 10 per cent alcohol. The result of this competition was made public on April 9, 1922, and revealed more than 100 formulas which were submitted to a specially instituted committee for exhaustive study.

The principal difficulty to be overcome in producing a suitable fuel is to bring about a homogeneous mixture of commercial alcohol and gasoline. The methods presented were classified into two general groups. In the first, a third liquid is added to act as a solvent for the mixture of commercial alcohol and gasoline, the main solvents suggested being butyl alcohol, cyclohexanol, noncaustic derivatives of cresols and isopropyl alcohol. In the second, methods were proposed for dehydrating commercial alcohol and thus making possible the comparatively easy mixture of absolute alcohol and gasoline.

Other suggestions involved the mixture of light oils and commercial alcohol, while still others proposed the use of fractions from the distillation of wood tar. Finally, another group of suggestions proposes the use of an easily obtained admixture of alcohol and an ether derived from alcohol.[18]

Iron and Steel

The iron and steel industry of France is one of great potentiality. She is now a leading producer of iron ore, and the market for this ore as well as for the finished product is most encouraging. For years to come she will have as her own best customer her war-devastated industries.

There is much talk in France and in Belgium about the policy of the French Government in raising an almost prohibitive tariff against the importation of finished products of iron and steel. Belgium especially resents this, as she is suffering quite as much from the French policy as she did from German competition. Another even stronger complaint of the Belgian metallurgist is that although the French compete effectively for export business, they prevent the importation of iron and steel even when Belgian bids are lower than their own. This leads to the conclusion that French metallurgical companies are getting for their products in their home market prices above those asked by the Belgians.[19]

Development of Hydro-Electric Power

The development of French hydro-electric power is very encouraging. A little over 2,000,000 hp. is now being developed, and new plants are constantly being built. In this connection the activities of the Electrochemical and Electrometallurgical Institute at the University of Grenoble have been of the greatest service, because through it France is enriched every year with a number of engineers particularly familiar with hydroelectric development. In addition to this, the magazine *La Houille Blanche*, devoted entirely to water power, is keeping the French engineers informed of progress in this important industry.

The electrification of the greater part of the French railways is seriously studied, but no definite plans have been announced. I was impressed with the great field for this development when I observed coal-fired interurban tramways within walking distance of the Romanche River in the Grenoble district with its many hydro-electric plants.

France as an Industrial Country

The potentiality of France as a great industrial country is conspicuous to an engineer traveling from border to border. It will be necessary for her to import fuel for many years to come, but the steady development of her water-power resources will enable her gradually to overcome this handicap. Her colonies will supply her with many of the raw materials which she is now lacking, and to a certain extent even with common labor. With respect to the latter, however, I learned that France is now making tempting offers in her western

[17] A summary of the proceedings of these meetings will form the subject a separate article in this journal.

[18] A detailed description of the effort to develop a national liquid fuel for France (Comburant National) will form the subject of a separate article in this magazine.

[19] The *Exportateur Belge* of July 9 cites the case of Belgian rails being offered in France at about 20 francs per ton less than the price asked by the French, and yet the Belgians did not get the order.

industrial districts for immigrants from Italy, Poland, Spain and other eastern and southeastern European countries.

France still has many difficulties to overcome, the principal one being her fear of German aggression, against which she feels the need of assurance. In consequence of this fear she is now in the full grip of a military preparedness policy that imposes upon her economic system a heavy burden in military expenditures, in addition to depriving her of the productive work of many hundreds of thousands of young Frenchmen.

Trip Through Italy and Switzerland

My trip through Italy and Switzerland was only of short duration and I did not have an opportunity to corroborate my first impressions by a subsequent trip. It must suffice, therefore, for me to say that both these countries are suffering from unemployment and that their economic ills are the consequence of the fact that Italian money is badly depreciated, while Swiss money is still worth its face value.

In Italy the domestic industries are suffering because, in the absence of domestic fuel and raw material, they are limited in their ability to import by the low exchange value of the lira. Apparently it is much cheaper to import finished German goods, especially in view of the German industrial policy of exporting at ridiculously low prices. I was told that practically all of the money received in payment for these imported products is invested by the German industrials in Italian industries, and that this policy is assuming alarming proportions.

In Switzerland, with her money at pre-war value, it is practically impossible for domestic industries to compete with those of any other European country. Accordingly, Germany is very active in supplying Switzerland with finished products, especially in view of the fact that they are paid for with Swiss francs, which are then placed to the account of the exporters in Swiss banks. Pre-war revenues from tourists, which formerly assumed large proportions, are now practically non-existent, due to the high cost of living. Switzerland is, therefore, among the least favored of the European countries from an economic point of view. As already shown in a previous article, Swiss manufacturers are reduced practically to the rôle of middlemen for German manufactured goods—a very pathetic situation.

Both Swiss and Italian banks, I was told, are enjoying a large and profitable business due to the abnormal conditions in international exchange, and the large volume of German commercial transactions.

At Geneva I had an opportunity to investigate the objects and workings of the International Bureau of Labor. This will form the subject of a separate article on this important adjunct of the League of Nations.

Other articles on this subject by Mr. Negru will appear in subsequent issues.

Weighing CO_2

IT HAS been recognized that excess air is the enemy to economy of boiler operation, and it is no longer unusual to see the engineer hunting for air leaks on the outside of the furnace with a smoky candle. Perhaps the one source of excess air which is most damaging and at the same time the most difficult to detect is a hole through the bed of fuel—in other words, what the fireman knows as a "hole in the fire." This, of course, may be caused in various ways. The fire may burn out faster at one point than at another, the fuel bed may not have been placed on the grate evenly, etc. In the case of hand fires, one of the principal duties of the fireman is to watch for such holes in the fire as they admit excess air, which, passing up the chimney, carries with it valuable heat.

Holes in the fire are difficult to detect in the case of some mechanical stokers, especially where boilers are placed close together in battery or there is a forced draft arrangement boxing in the grates. To detect holes in the fire should be one of the principal functions of the CO_2 apparatus, and to do this the apparatus should be of such a nature and location as to communicate the message to the fireman promptly. In other words, as a steam gage indicating the boiler pressure located in the chief engineer's office would be very little help to the fireman, so also the CO_2 apparatus placed too far away from the firing floor is of little use to him.

There is another difficulty with some CO_2 apparatus as it exists today, and that is that the scheme depends on the dissolving of the CO_2 gas in potassium hydrate solution. This means that the apparatus is, in a sense of the word, a small chemical laboratory. It is slow in operation, expensive, more or less troublesome to maintain, so placed as to be of little use to the man on the firing floor and, above all, necessarily operating in such a way as to deliver its message some little time after the condition took place in the furnace. So far as the CO_2 apparatus is concerned, the fireman is still going it blind as a general thing.

Some months ago Dr. Zacharius Olsson, who has had considerable experience in power house work, had his attention called to the inadequacy of the present method of following excess air and CO_2 from the standpoint of the man on the firing floor. Appreciating how valuable it would be to the fireman to have some sort of an indicator that could be placed on the front of the boiler exactly as the steam gage is placed and which would require no more attention than does the steam gage, Dr. Olsson conceived the idea of building a CO_2 apparatus which would weigh the gases as they pass through and indicate differences in CO_2 percentage by gravity rather than to use the principle of dissolving them in solution with all the attendant evils of the small laboratory. There would be no solutions, no glass containers, no laboratory—simply a weighing machine reduced to its lowest terms and of the simplest possible nature.

The writer remembers a visit to Dr. Olsson's laboratory at Staten Island where he saw this gravity CO_2 apparatus attached to a small heater. It was interesting to note how the doctor could make the pointer go down from 14 per cent to zero in 3 or 4 seconds by opening the fire door, bringing it back to maximum again almost instantaneously by reversing the process. This might be called remarkable considering the lag of the ordinary apparatus due to the necessity of dissolving and measuring the sample of gas.

No large modern boiler plant is now considered efficient or complete unless it has been provided with steam flow meters, automatic feed regulators, draft control, soot blowers, feed water treatment and control, pyrometers and, not least of all, CO_2 apparatus. Dr. Olsson's CO_2 indicator will go a long way toward bringing this particular instrument into the easy range of vision of the man handling the shovel.

Decarburizing Ferrochromium by Hydrogen

By Louis Jordan and F. E. Swindells
Chemist and Assistant Chemist Bureau of Standards

Rustless Iron

CONSIDERABLE publicity has recently been given to the development in England of a rustless or stainless iron and the uses to which such material may be put. Stainless steel has become a familiar class of material. It contains in the neighborhood of 13 to 16 per cent chromium and usually 0.3 to 0.4 per cent carbon. Rustless iron contains about the same proportions of chromium, but its carbon content is lower, in the neighborhood of or less than 0.1 per cent.

Some of the advantages claimed for rustless iron[1] over stainless steel are that it is more ductile, more easily rolled or forged, does not require special heat-treatmnt of the ingots before working, and machines more readily. It is said to have stainless or rustless properties close to those of stainless steel. It is also stated that marine growths will not adhere to plates rolled from rustless iron.

Need for Low-Carbon Ferrochromium

Commercial ferrochromium contains 60 per cent chromium and 4 to 8 per cent carbon. In order to produce an iron alloy containing not over 0.1 per cent carbon and as high as 12 per cent chromium it is evident that such alloy cannot be used. In order to produce a 12 per cent chromium alloy with not over 0.1 per cent carbon a 60 per cent ferro should contain not more than 0.5 per cent carbon.

"Carbon-free" metallic chromium and ferrochromium is manufactured by aluminothermic reduction methods. These materials, however, command 40 to 60 cents per pound of contained chromium, as against about 11 cents for the ferro containing 4 to 6 per cent carbon. Chromium in 100 lb. of rustless iron would cost from $4.80 to $7.20 when added as carbon-free aluminothermic alloys. Rustless iron would thus be too seriously handicapped in commercial uses compared with ingot iron, copper-bearing steel, or many non-ferrous metals.

It is reported that an English process for low-carbon ferrochromium enables a selling price of 20 cents per pound for ferro containing only 0.25 per cent carbon.[2]

Refining High-Carbon Ferrochromium

Recent patents have described the production of low-carbon ferrochromium by subjecting crude, high-carbon ferro to an oxidizing blast in a converter;[3] to electric furnace treatment with oxides of iron or chromium,[4] or of titanium,[5] or by blowing molten high-carbon ferrochromium in a converter with the injection into the blast of steam, or some other gas or vapor.[6] Ballantine has also patented[7] the method of reduction of chromium oxides with calcium carbide in the presence of an alkaline earth oxide with or without calcium silicide or aluminum. A still more recent patent[8] claims the method of producing rustless steel containing low carbon by adding a mixture of aluminum and chromium ore to a molten decarburized steel in an electric furnace.

Decarburization by Hydrogen

The use of hydrogen for the removal of carbon from iron and iron alloys has previously been suggested and demonstrated experimentally. Schmitz[9] showed that heating cast iron in hydrogen at 1,200 deg. C. for ½ hr. reduced the carbon from 3.46 per cent to 2.74; by further successive heatings of 2 to 3 hours each the carbon was reduced to 2.16, 1.38, 0.53, and finally to 0.03 per cent. Plain carbon steels were appreciably decarburized in 15 to 35 minutes at 1,200 deg. C. A 25 per cent nickel steel containing 0.99 per cent carbon was treated three successive times for 2 hours each. The carbon dropped to 0.61, 0.11 and 0.08 in the successive heatings. Schmitz also heated 0.05 gram of "kish" for 15 hours at 1,100 deg. C. in hydrogen; it lost 63 per cent of its weight. A 0.2-gram sample of graphite heated 3 hours at 1,000 deg. C. in hydrogen lost 8.7 per cent of its weight.

Campbell[10] decarburized several steels by heating in moist hydrogen at 950 to 1,000 deg. C. for 4 to 12 days. Chromium-molybdenum steel of an original carbon content of 1.67 per cent was reduced to 0.22 per cent after 12 days at 950 to 1,050 deg. C. Campbell concludes from results on plain carbon and alloy steels that pure carbides of iron are less stable when in solid solution than are the carbides which are formed if some other elements are present—e.g., manganese.

Austin[11] has recently described the surface decarburization of three carbon steels treated in both moist and dry hydrogen at several temperatures between 400 and 1,000 deg. C.

Ferrochromium used in the present tests was a commercial grade crushed to pass 80 mesh. This fine material contained 56.6 per cent chromium and 8.47 per cent carbon. The results of all tests are summarized in Table I.

Action of Hydrogen on Solid Ferrochromium

Twenty grams of the material was placed in a silica boat and heated within a silica tube at 900 deg. C. in a nichrome-wound electric combustion furnace. Temperatures in all runs in tube furnaces were controlled by the power consumption of the furnace, a calibration having previously been made with the thermocouple placed in the usual position of the boat. Hydrogen gas used was commercial compressed hydrogen purified by passing successively through tubes containing soda lime, platinized silica at a red heat, concentrated sulphuric acid and phosphorus pentoxide. Carbon dioxide, oxygen and moisture should be removed by this purification.

In the first trial the pure dry hydrogen was passed over the sample of ferrochromium for 1 hour after the furnace tube reached the desired temperature. The rate of passage of hydrogen was 4½ liters per hour. Three-quarters of an hour was required for the boat to reach 900 deg. C. The sample was cooled in the stream of hydrogen. Analysis of the treated sample showed no loss in carbon. (Table I.)

TABLE I—DECARBURIZATION OF FERROCHROMIUM BY HEATING IN HYDROGEN

Run No.	Duration of Run; At Max. Temp. Hr.	Min.	Approx. Temp. Fe-Cr., Deg. C.	Carbon in Original Fe-Cr, Per Cent	Carbon in Fe-Cr After Treatment, Per Cent	Reduction in Per Cent Carbon In Fe-Cr.	Remarks
1	1	0	900	8.47	8.57	....	.....
2	1	30	1,000	8.47	8.14	0.33	Fe-Cr, noticeably oxidized after treatment. Moist hydrogen used.
3	3	30	1,000	8.47	8.14	.33	Fe-Cr, oxidized. Moist hydrogen used.
4*a*	4	15	1,100	8.47	8.16	.31	Fe-Cr, bright, indicating no oxidation.
4*b*	2	45	1,100	8.16	8.14	.02	Residue from Run 4*a* reheated.
4*c*	4	15	1,100	8.14	7.88	.26	Residue from Run 4*b* reheated.
7	4	0	1,350	8.41	6.54	1.87	Unfused portion.
					5.21	3.20	Fused portion.
8	4	0	1,350	8.41	6.80	1.61	Unfused portion.
					6.23	2.18	Fused portion.
9	..	4	1,500–1,600	8.47	7.50	0.97	Hydrogen bubbled through molten Fe-Cr.
10	..	20	1,600–1,700	8.47	6.91	1.56	Hydrogen blown on surface of molten Fe-Cr.

The conditions in run 2 were modified to conform more nearly to those used by Campbell[10] in the decarburization of steels. The hydrogen, free from oxygen, was bubbled through water at room temperature before passing into the furnace. The temperature of the furnace was raised to 1,000 deg. C. The heating period: 1 hour to reach 1,000 deg. C. and 1½ hours at full temperature. The carbon in the sample after treatment was 8.14 per cent, a drop of 0.33. A longer test, other conditions being repeated, gave no greater loss in carbon. In both runs, the ferrochromium was noticeably oxidized. Carbon may have been lost due to oxidation by moisture rather than reduction by hydrogen.

Consequently, in trials 4a to 4c the hydrogen entered the furnace dry. At the same time the temperature was increased to 1,100 deg. C. Tests 4b and 4c (Table I) represent a second treatment of the ferro-alloy used in 4a and 4b, a small sample for carbon determination being removed between heatings. For runs 4a to 4c the total time of heating was 11¼ hours, but the total loss in carbon was only 0.57 per cent. After treatment the ferro was bright and not oxidized.

It thus appears that somewhere between 900 and 1,100 deg. C. the reduction of carbon by dry hydrogen became appreciable, although the reaction was slow at the upper temperature. The next tests were made with a still further increase of temperature.

A platinum-wound tube furnace was used in runs 7 and 8. A porcelain tube was used to contain the boat and sample, and in experiment 7 the boat also was of porcelain. The furnace was operated at 1,350 deg. C. and the hydrogen was thoroughly dried as before. When the boat was removed (after 4 hours' heating) it was found that the ferro-alloy in one end had melted, while in the other end it was slightly sintered. Analysis showed a loss of 1.87 per cent carbon in the unfused portion and 3.20 per cent in the fused portion. There were indications of some attack of the glaze of the porcelain boat by the molten ferrochromium, and the greater loss of carbon in the fused portion might have been caused by reaction with this glaze.

In the next trial all conditions were identical with the exception that an alundum boat was used. After heating, the sample was found to have been partly melted as in run 7. The loss of carbon was 1.61 per cent in the unfused portion and 2.18 in the fused.

The two tests at 1,350 deg. C. pointed to the conclusion that there is a sudden and marked change in the rate of decarburization at the melting point of the ferro-alloy. The Krupp patent[6] seems to cover the use of any gas or vapor in the blast of the bessemer converter. The above tests would indicate that hydrogen might be used effectively in such a manner.

Action of Hydrogen on Molten Ferrochromium

To obain some indication of the effectiveness of blowing molten ferrochromium with hydrogen, two tests (Nos. 9 and 10) were made in which the ferro-alloy was melted in a high-frequency induction furnace. The alloy in experiment 9 was melted in a magnesia crucible under a stream of hydrogen and then held somewhat above 1,500 deg. C. and dry hydrogen bubbled through the melt for 4 minutes by means of a fused silica tube leading to the bottom of the crucible. This silica tube was corroded slightly. Carbon was reduced from 8.47 to 7.50. That this loss in carbon was not due to oxidation by silica from the small tube was indicated by the fact that the silicon in the original ferro-alloy was 0.87 per cent, while after run 9 it was 0.55 per cent. The efficacy of blowing molten ferrochromium with hydrogen is striking when compared with the reduction of 1.87 per cent in the unfused alloy after heating for 4 hours at approximately 1,350 deg. C.

Molten metal heated by direct induction is very rapidly stirred by the magnetic flux. It was thought worth the trial to make a test in which hydrogen was blown only on the surface of molten and rapidly stirred ferrochromium. For run 10 the alloy was melted in a crucible made of 85 per cent magnesia and 15 per cent zirconium silicate. The molten metal was unintentionally permitted to attain a temperature of 1,700 deg. C., a much higher temperature than in run 9, and the silica tube through which the hydrogen was flowing was rapidly melted off at the end, although not touching the molten metal. Hydrogen was blown on the surface of the melt for 20 minutes.

The carbon content of the alloy in this run was reduced from the original 8.47 to 6.91, a loss of 1.56 per cent. This loss in carbon was caused in large part by the reduction of silica at this high temperature, as is indicated by the increase of the silicon content of the ferrochromium from the original 0.87 to 1.61 per cent.

Summary

These preliminary tests indicate that while the decarburization of ferrochromium by means of hydrogen takes place to some extent at temperatures below the melting point of the alloy, the most promising condition for refining high-carbon alloy by this method is probably by blowing the molten alloy with a blast of hydrogen in a converter.

Metal Corrosion Report

"Corrosion of Metals and Materials by Acids and Alkalis" is a report by Maurice Siegel, who has made an elaborate study for the Chemical Division of the Chemical Warfare Service. The report is made up of an extended discussion of the theoretical considerations and practical methods of measuring corrosion, supplemented by a full bibliography and a tabular summary of many hundred experimental results which have been calculated to a common basis of presentation. It may be obtained from the Chief of Chemical Warfare Service, Washington.

Evaporation—A Study of the Various Operating Cycles In Triple Effect Units

By A. L. Webre
Consulting Engineer

A General Method of Discovering the Best Operating Cycle for Triple Effect Evaporators Described—"Heat Balance" Worked Out for a Sample Case and the Type of Conclusions Which Can Be Reached Is Indicated

WE WERE TAUGHT in the old textbooks, and are still taught in some of the new ones, that in a multiple-effect evaporator, for each pound of steam supplied to the equipment, we obtain 1 lb. of evaporation in each vessel. This is not exactly true under any condition, and far from being true under average operating conditions. It was originally based on the assumption that for all pressures existing in the various bodies the latent heat of steam, L, was constant and to all intents and purposes 1,000 B.t.u. per pound. That this assumption is not justified is shown by the curve in Fig. 1, which shows the varying values of this latent heat within the range of temperatures commonly encountered in evaporator practice.

Another error which is quite prevalent is the fact that the liquid fed to the evaporator passes usually through the various bodies in series, from the high-temperature end to the low-temperature end, and as it goes from a hot to a cooler body a "flash," or self-evaporation, takes place, bringing the feed down to the temperature of the body into which it is entering. When this evaporation is taken into account, it has a very material effect on the balances of heat flow, depending upon the weight per unit of time and the range of temperature fall.

Temperature of Feed Liquor Most Important

By far the largest variable in estimating the amount of evaporation per pound of steam is the temperature of the liquid as it enters the multiple effect, as compared with the existing boiling temperature in the first body. Obviously if the liquid must be heated to the boiling temperature, steam must be used up which would otherwise be available for evaporation. On the other hand, if the liquid temperature is higher than that in the first body, a "flash" takes place and actually more than a pound of water will be evaporated per pound of steam. The same condition exists as a rule in the subsequent bodies of a multiple, since there is always a "flash," and the evaporation will be greater than the amount of vapor condensed on the steam side. Therefore, in making calculations of the evaporation possible in a given effect it is a matter of balancing the latent heat available from the condensation of steam in the calandria against the latent heat represented by evaporation on the liquor side, to which must be added the heat required to bring the liquor to a boil if it is too cold, or from which must be subtracted the heat represented by "flash" if it is too hot.

The Use and Calculation of Heat Balances

The only way to determine accurately the operation of an evaporator is by making a thorough study of the heat transferred, with the aid of a heat and liquor flow sheet, or heat balance, in which all the steps and their interrelations are shown. When conditions are known, it is not difficult, and this method of analysis permits us to acquire a comprehensive grasp of relatively complicated evaporator problems. We shall illustrate by submitting an analysis of what to our mind is one of the most interesting problems in evaporation—namely, the determination of the most advisable cycle of feed, governed by the consideration of steam economy alone.

Let us assume that we have a triple effect, whose bodies are numbered 1, 2, 3, beginning at the steam end and finishing at the condenser end. The question we wish to discuss is this:

All conditions being precisely the same, with the exception of the temperature of the liquid entering, which is variable, is it advantageous that the feed shall go through the three bodies in series, 1, 2, 3, commonly known as "parallel current," or 3, 2, 1, "counter-current," or shall each body be fed independently?

There are many conditions aside from heat economy which preclude the possibility of using some of these cycles, but we shall in this case assume that heat economy is the only determining factor.

In order to avoid unnecessary complications which would cloud the issue, we will arbitrarily assume the following conditions, which are not perhaps what we would find in practice, but which will serve well enough for this discussion, which we do not wish to complicate by the introduction of some forty-odd variables entering in evaporator work:

Liquid to be treated per hour	100,000 lb.
Evaporation required	70,000 lb.
Evaporation in triple effect.	
Initial feed temperature	Unknown and variable
Specific heat of solution	Unity
Viscosity	Negligible
Boiling temperature rise	Negligible

	St. Belt 1	St. Belt 2	St. Belt 3	Vapor Belt 3
Press and vac..	5.0 lb.	2 in vac.	14 in vac.	26 in vac.
Temperature...	227 deg.	209 deg.	182 deg.	125 deg.
Latent heat....	960.7 B.t.u.	972.2 B.t.u.	988.7 B.t.u.	1021.6 B.t.u.

Complete heat balances have been calculated for "parallel current" operation, also for "counter-current" and "parallel feed" for initial feed temperatures of 50, 100, 150, 200 and 250 deg. It would take up too much space to give them all completely here. We have therefore made abstracts for each cycle, giving the information required to compare performances. We shall detail for illustration one of these heat balances for each cycle, calculated for a feed temperature of 150 deg., as representing probable average conditions encountered in practice.

Calculation of "Parallel Current" Heat Balance

In the calculation given in Table I, we begin by admitting into the steam belt of the first effect 27,800 lb.[1] of steam per hour at a pressure of 5 lb. gage, corresponding to a temperature of 227, which upon condensation gives up its latent heat 960.7 B.t.u. per pound, making a total of 26,700,000 B.t.u. liberated.

[1]This figure is reached by a process of trial and error which necessitated calculating the complete heat balance after assuming this initial figure. Three or four calculations are usually sufficient to arrive at a figure which will check out within operating limits of accuracy.

TABLE I—PARALLEL CURRENT HEAT BALANCE
Feed Temperature = 150 deg. F.

Specifications:	Heat	Liquor
(1) Steam, 27,800 lb. @ 5 lb. = 27,800 × 960.7 =	26,700,000	100,000
Deduct for heating 100,000 × (209 − 150 = 59)	5,900,000	
Available for evaporation	20,800,000	
L @ 209 = 972.2. $E_1 = \frac{20,800,000}{972.2}$ =		21,400
		78,600
(2) Vapor ex. 1	20,800,000	
Add flash, 78,600 × (209 − 182 = 27) =	2,120,000	
Available for evaporation	22,920,000	
L @ 182 = 988.7. $E_2 = \frac{22,920,000}{988.7}$ =		23,200
		55,400
(3) Vapor ex. 2	22,920,000	
Add flash, 55,400 × (182 − 125 = 57) =	3,160,000	
Available for evaporation	26,080,000	
L @ 125 = 1,021.6. $E_3 = \frac{26,080,000}{1,021.6}$ =		25,500
Excess		29,900

This is transmitted to the liquor through the heating surface, part of it being used to bring the feed temperature to the boiling point, in this case, 209. The initial temperature being 150, the necessary rise is 209 — 150, or 59. Inasmuch as the entire feed enters the first body, we must heat it all, 100,000 lb., through this rise of 59 deg., thus absorbing 5,900,000 B.t.u. The heat left available for evaporation is therefore 26,700,000 — 5,900,000, or 20,800,000 B.t.u. The latent heat at the temperature of ebullition, 209 in the first effect, is 972.2 B.t.u. per pound. The evaporation in the first effect will therefore be 20,800,000 divided by 972.2, or 21,400 lb., and the amount of feed transferred from the first to the second effect will be the amount of the original feed, 100,000 lb., less this evaporation, 21,400, or 78,600.

For the second effect, we obtain heat from two sources: First, the vapor from the first effect, which upon condensation gives up its latent heat, shown above

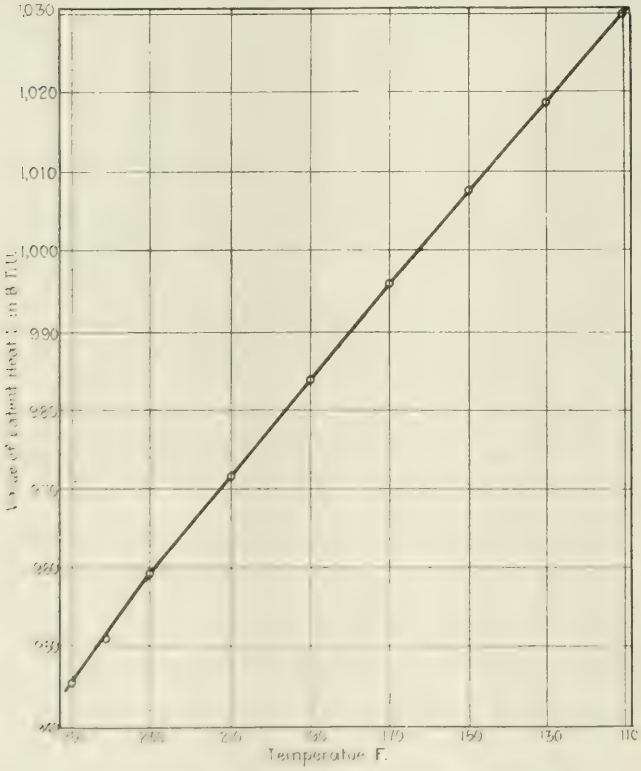

FIG. 1—VARIATION OF LATENT HEAT WITH TEMPERATURE

to be 20,800,000 B.t.u.; and second, the heat obtained from the flash or self-evaporation taking place when the feed leaves the first body at a temperature of 209 and enters the second at 182, thus giving up 27 B.t.u. per pound. The amount of this liquor being 78,600, as shown above, the total heat liberated in this way will be 78,600 times 27, or 2,120,000 B.t.u., making a total of 22,920,000 available for evaporation in the second body. The latent heat at this point at the existing temperature of 182 is 988.7 B.t.u. per pound, and the corresponding evaporation will be 22,920,000 divided by 988.7, or 23,200, and the liquor transferred from the second to the third effect will be the amount which entered this body, 78,600, less this evaporation, 23,200, or 55,400 lb. per hour.

A similar exchange takes place in the third effect. First the vapor from the second body condenses, giving up its latent heat, shown above to be 22,920,000 B.t.u., and the feed from the second flashes down from its original temperature of 182 to that of the third effect, 125, thus giving up 57 B.t.u. per pound. The quantity being 55,400 lb., the heat thus liberated is 3,160,000 B.t.u., which when added to the above gives us a total

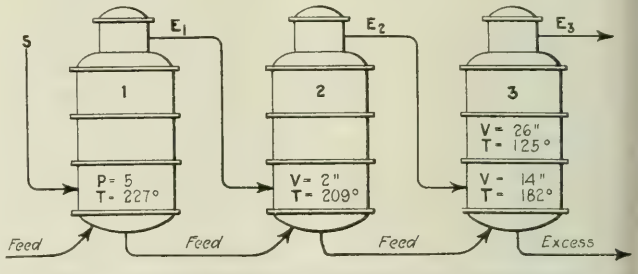

FIG. 2—DIAGRAMMATIC SKETCH OF PARALLEL CURRENT OPERATION

of 26,080,000 available for evaporation in the third effect. The latent heat of steam at the third body temperature, 125, is 1,021.6 B.t.u. per pound, and the evaporation here is therefore 25,500 lb. per hour, which when deducted from the feed into the third effect, 55,400 lb., leaves 29,900 lb. which is removed from the last body as concentrated liquor. This compares closely with the 30,000 which we should obtain. The variation is negligible.

Fig. 2 is a diagram plotted from a summary of the five heat balances calculated for various feed temperatures for "parallel current" operation, which represents the cycle used most extensively. The reader must bear in mind that in all these cases the total evaporation for the triple effect is the same—namely, 70,000 lb. per hour—and the total feed is the same, 100,000 lb. per hour. The only variation is in the temperature of this feed. The steam supply is then varied to give 70,000 lb. evaporation per hour in all cases. With the "parallel current" cycle the evaporation in each body does not vary as the temperature of the feed changes. By referring again to the heat balance shown in Table I the reason for this can be readily seen. In order to accomplish the evaporation required, the first body must produce 21,400 lb. of vapor. In order to do this, there must be available for evaporation 20,800,000 B.t.u. If the liquor enters at the boiling point, then we must put into the steam belt of the first effect 20,800,000 B.t.u. by condensing the corresponding amount of steam. If the feed is below the boiling point, we must add sufficient heat to bring it to a boil, increasing the steam consumption to that extent. If, on the other hand,

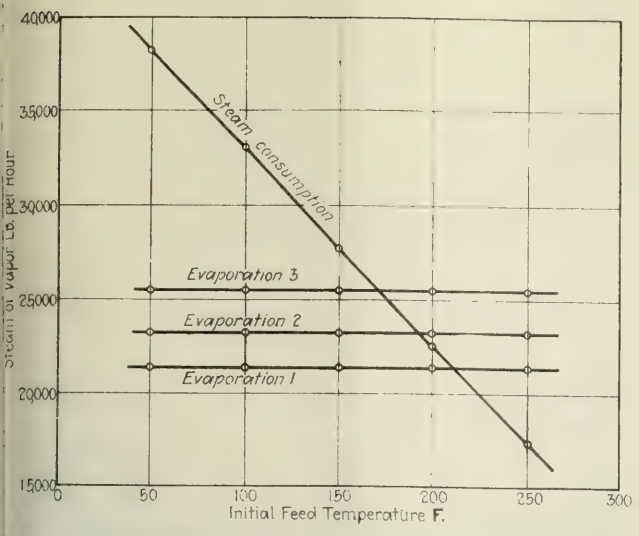

FIG. 3—TRIPLE EFFECT PERFORMANCE WITH PARALLEL CURRENT OPERATION AT VARYING TEMPERATURES

iquor enters above the boiling point, a corresponding lash takes place, liberating a certain amount of heat, hus decreasing the amount of steam required to make ıp the necessary 20,800,000 B.t.u. as vapor leaving the irst body. The evaporation is greater in the second han in the first effect, and greater in the third than in he second, for reasons discussed previously. The tem- erature of the concentrated liquid is 125 deg. F. It ıust be noted that the steam consumption varies within ather wide limits as the feed temperature changes, a act well worth remembering.

"Counter-Current" Heat Balance

We shall now go over the calculations for the counter-current" heat balance, summarized in Table I. In this case we find it easier to work backward, nasmuch as the feed flows backward.

We begin by feeding into the third effect 100,000 lb. f liquor at the given temperature of 150. We evap- rate by assumption 22,880 lb. at this point. The tent heat of steam at the existing temperature, 125, 1,021.6 B.t.u. per pound, and the heat in this vapor therefore 22,880 times 1,021.6, or 23,360,000. Part this heat is derived from the flash or self-evaporation the feed, 100,000 lb., which enters at 150 deg., opping down to the boiling point, 125, and giving up 5 B.t.u. per pound, or a total of 2,500,000 B.t.u. Inas- uch as the vapor contains 23,360,000 B.t.u., as stated ove, the difference, 20,860.000 B.t.u., must be made by the condensation in the steam belt of the third effect of vapors from the second at a temperature of 182, having a latent heat of 988.7 B.t.u. per pound. The amount of vapor thus condensed will therefore be 20,860,000 divided by 988.7, or 21,100 lb., which of course represents the evaporation in the second effect.

The feed transferred from the third to the second effect is the total feed, 100,000 lb., less the evaporation in the third effect, shown above by assumption to be 22 880 lb., giving us 77,120.

In the second effect, we must supply not only the latent heat contained in the vapors going to the third, shown above to be 20,860,000 B.t.u., but in addition we must heat up the feed, 77,120 lb., transferred from the third effect at a temperature of 125 to the second at a temperature of 182, a rise of 57 deg., giving us 77,120 times 57, or 4,400,000 B.t.u., which when added to the latent heat of the vapor above, 20,860,000, gives 25,260,000 B.t.u. as the total heat requirements in the steam belt of the second body. Now the temperature of this steam is 209 and the latent heat for this is 972.2. The amount of steam condensed in the steam belt of the second effect will therefore be 25,260,000 divided by 972.2, or 26,000 lb., which is also the evaporation in the first effect.

The feed transferred from the second to the first effect will be the amount fed into the second from the third, 77,120, less the evaporation in the second, shown above to be 21,100, or 56,020 lb.

In the first effect, we must also provide heat enough to correspond to that contained in the vapors therefrom, given above as 25,260,000 B.t.u., plus the heat required to bring up the feed, 56,020 lb., from the temperature of the second body, 182, to the temperature of the first, 209, a rise of 27 deg., thus making up 56,020 times 27, or 1,511,000 B.t.u., which, when added to the heat in the vapors from this effect, 25,260,000, gives a total of 26,771,000 B.t.u. This heat must be supplied by condensing steam in the first steam belt at a temperature of 227, at which the latent heat of steam is 960.7 B.t.u. per pound. The quantity of steam required is therefore 26,771,000 divided by 960.7, or 27,850 lb. per hour.

The concentrated liquor discharged from the first effect will be the amount fed from the second to the first, 56,020, minus the evaporation in the first, shown above to be 26,000, giving us 30,020. In this case also, by premise, this quantity should be 30,000.

In Fig. 5 the heat balances are plotted graphically for different temperatures. The feed enters the third body, and is pumped from there to the second and then to the first, going in opposite direction to the steam, hence the name. The evaporation in each body varies considerably as the initial feed temperature changes. The steam consumption as well as the evaporation in the first and second effect decreases as the feed tem-

			69,900

perature increases. The evaporation in the third effect, however, does just the opposite. This is readily understood by studying the heat balance.

When the feed temperature is below 125, as it enters the last body, it must be heated up before it evaporates, thereby increasing the heat requirements in the steam belt. When this temperature, however, is higher than 125, a flash takes place, and this vapor is not used in multiple, but goes directly to the condenser. Thus, in the case of feed at 250, there is 12,500,000 B.t.u. liberated as flash and 17,750,000 of transmitted heat, making a total of 30,250,000 B.t.u. in vapor to the condenser. With temperature of feed at 50 deg. F., just the reverse takes place. There is 24,050,000 of transmitted heat, of which 7,500,000 is used in bringing the liquid to a boil and 16,550,000 represented as vapor.

It is to be noted that with counter-current operation there is a flash only in the last body and only when the temperature of the entering feed is above 125 deg. F., the boiling point. Except where there is a flash, each preceding body evaporates more than the succeeding one, for the liquid must be heated in each case before it evaporates, thus increasing the heat requirements of

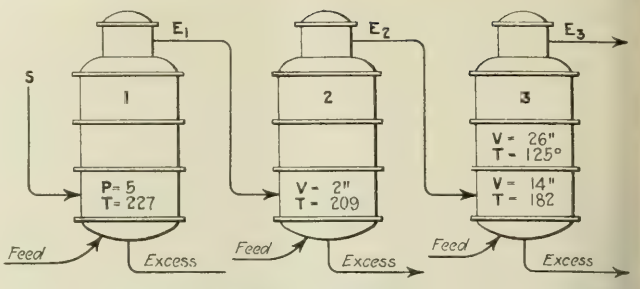

FIG. 6—DIAGRAMMATIC SKETCH OF PARALLEL FEED OPERATION

the second body over the third and the first over the second.

Generally speaking, the load on the condenser (the evaporation in the last effect) is much less than with "parallel current" operation, especially at low feed temperatures. It is also to be noted that the concentrated liquid leaves the first effect at a temperature of 209, as against 125 for parallel current operation, a fact well worth considering if subsequent heating operations are required after the concentrated material leaves the apparatus. When viscous materials are to be evaporated, it is very advantageous to operate "counter-current," as, in view of the high temperatures at high concentration, the annoying effects of high viscosity are very much reduced.

Parallel Feed Heat Balance

Parallel feed heat balance is calculated with initial feed at 150 deg. F., as before. (*Cf.* Table III and Fig. 7.) We begin by admitting 26,700 lb. of steam into the calandria of the first effect, obtaining for useful work its latent heat at the existing temperature 227, which is 960.7 B.t.u. per pound. The heat thus liberated is therefore 25,680,000 B.t.u. Each pound evaporated will require in the first place an amount of heat equal to the latent heat at the temperature existing in the first effect, 209, or 972.2 B.t.u. This pound which we are to evaporate represents only 70 per cent of the corresponding liquor fed, for, by premise, we evaporate 70 per cent by weight in each body. We must heat this liquor from its initial temperature of 150 to the temperature of the first body, 209, a range of 59 deg.; therefore the amount of heat required for this operation will be 59 divided by 0.7, or 84.3 B.t.u. per pound of evaporation, which when added to the latent heat above, 972.2, gives a total of

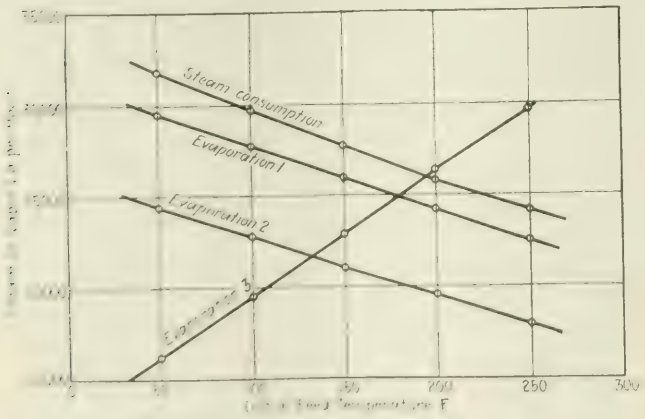

FIG. 5—TRIPLE EFFECT PERFORMANCE WITH COUNTER-CURRENT OPERATION AT VARYING TEMPERATURES

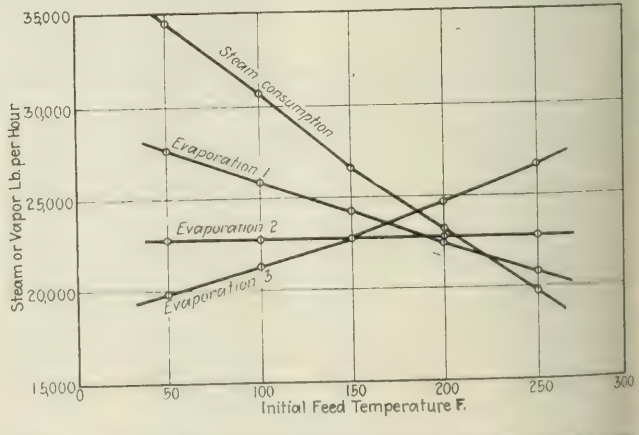

FIG. 7—TRIPLE EFFECT PERFORMANCE WITH PARALLEL FEED AT VARYING TEMPERATURES

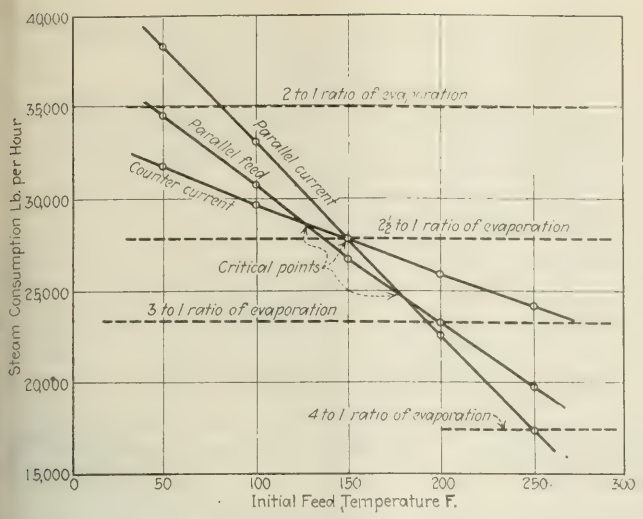

FIG. 8—COMPARISON OF STEAM CONSUMPTION WITH DIFFERENT METHODS OF OPERATION AND AT VARYING TEMPERATURES

1,056.5. The evaporation in the first effect will therefore be the total heat available given above as 25,680,000 divided by this 1,056.5, or 24,300 lb. per hour.

In the second effect, when this vapor condenses, it gives up its latent heat only, or 972.2 B.t.u. per pound. The available heat at this point will therefore be 24,300 times 972.2, or 23,600,000 B.t.u.

The heat required per pound of evaporation will be the latent heat at the temperature of the second effect, 182, which is 988.7, to which must be added the necessary amount to bring up the feed from 150 to 182, a rise of 32 deg. Here again the evaporation represents only 70 per cent of the liquor fed in, and this heating will therefore require 32 divided by 0.7, or 45.7, which when added to the latent heat above, 988.7, gives us 1,034.4 B.t.u. required for each pound of evaporation as before. The total heat available was shown above to be 23,600,000 B.t.u., and the evaporation is therefore 22,800 lb. per hour.

As in the case of the second effect, when this vapor condenses in the third steam belt it gives up only its latent heat, stated above as 988.7 B.t.u. per pound. The heat available for evaporation in the third effect is therefore 22,800 times 988.7, or 22,550,000 B.t.u.

The heat required per pound of evaporation will be, as before, the latent heat of steam at the temperature of the third effect, 125, which is 1,021.6. The correction for the heating effect in this case is negative, for the feed enters at a temperature of 150, which is 25 deg. higher than that of the third effect. A flash will therefore result liberating 25 divided by 0.7, or 35.7 B.t.u. per pound of evaporation. Deducting this from the latent heat of steam for this temperature, given above as 1,021.6, we have 985.9 B.t.u. as the amount of heat required for each pound of evaporation in the last effect. The available heat in vapors from the second body is given above as 22,550,000 B.t.u. The evaporation is therefore 22,800.

The total evaporation for the entire equipment is as follows:

First effect	24,300
Second effect	22,800
Third effect	22,800
Total	69,900

By premise this amount should be 70,000, and the discrepancy is therefore 100 lb. per hour.

In the case of "parallel feed" operation each body of the triple is fed independently, and the concentrated liquor removed separately from each. In performance, this cycle lies roughly between the other two. It has only very few limited applications in practice, and is discussed here more as a matter of interest. Perhaps its most important use is in the salt industry, where we start with saturated brine and the same concentration exists in each body. It is true that for a certain limited range it is more economical than either of the other two cycles, in this case, from feed at 125 to feed at 175. According to the temperature of the feed, there may be flashing in all bodies, heating in all bodies, or heating in some and flash in others. The steam consumption decreases as the temperature of the feed increases; so does the evaporation in the first effect. The evaporation in the second effect is practically constant, and in the third increases as the feed temperature increases.

Conclusions

Variation in Steam Consumption in Various Cycles

Fig. 8 shows a comparison of the steam consumption of the triple effect with varying feed temperatures, operated according to the various cycles suggested above. The crossing point of the parallel and counter-current curves is at a temperature of 150 deg. F. We wish to particularly warn our readers that this critical point applies only for our assumed conditions, and would be different if these conditions are changed. We can say, therefore, that under our prescribed conditions, the "parallel current" method of operation is more economical if the temperature of feed is above 150 deg. F., and the "counter-current" if this temperature is less than 150.

Condenser Load Variations

Fig. 9 indicates the varying load on the condenser, which of course is the same as the evaporation on the last effect. This is worked out for the three cycles for all temperatures. There is a decided advantage here in favor of the "counter-current" cycle at lower feed temperatures.

The amount of evaporation in every case is the same by premise for the whole equipment—namely, 70,000 lb. per hour. If we divide this figure by the steam consumption in any particular case, we have the ratio of evaporation in pounds of evaporation per pound of steam used in the equipment. These data we have worked out as shown in the accompanying log and Fig. 10.

In view of the discussion at the beginning of this article, it is of interest to note the wide divergence from accepted information. These curves also bring out very forcibly the importance of keeping the feed

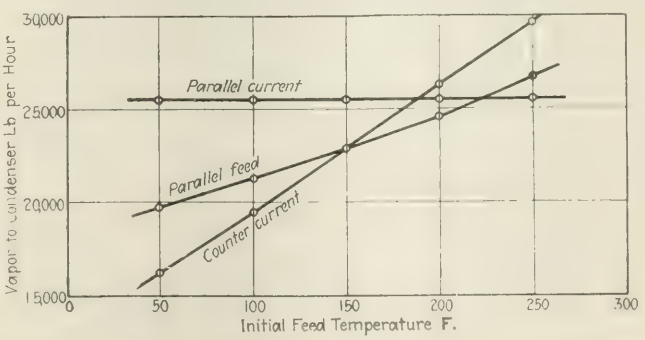

FIG. 9—CONDENSER LOAD UNDER VARYING CONDITIONS

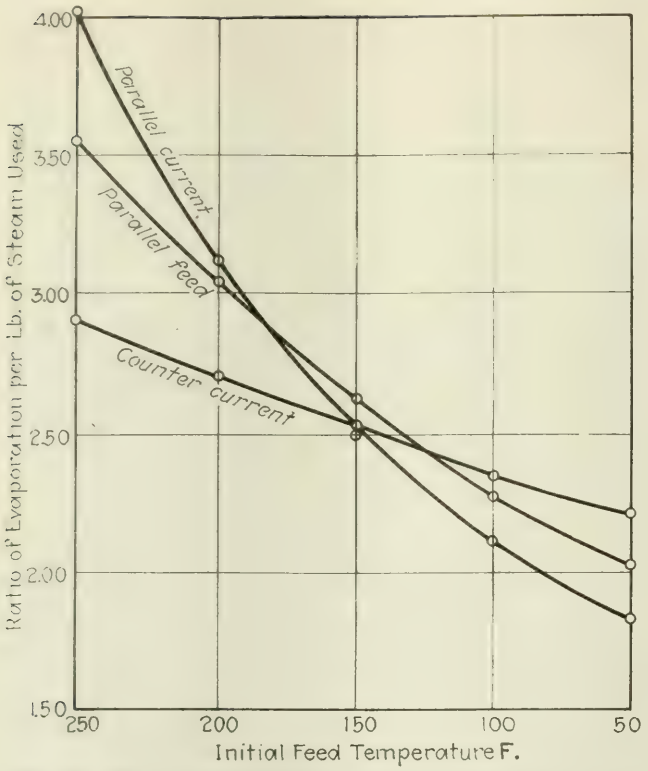

FIG. 10—EVAPORATION PER POUND OF STEAM UNDER VARYING CONDITIONS

temperature as hot as possible, and of keeping it so when once attained, if steam economy is of any consequence.

Importance of Detailed Study of Evaporator Problems

There is a general tendency among both builders and users of evaporators to discount the importance and magnitude of a thorough analysis of their problems for the purpose of arriving at the best solution, and before closing, we cannot refrain from calling attention to the unusually large number of interrelated and independent variables which enter into this work. Below we have listed some of the more important items to consider:

(1) Design of evaporator.
(2) Size of evaporator.
(3) Number of bodies possible, advisable and permissible.
(4) Diameter of tubes.
(5) Length of tubes.
(6) Thickness of tubes.
(7) Material of which they are made.
(8) Material of which the evaporator is made.
(9) Method of admitting feed.
(10) Method of removing feed.
(11) Method of feed control.
(12) Level at which liquor is carried.
(13) Proportion and arrangement of downtakes.
(14) Effect of various rates of liquor circulation.
(15) Effect of various rates of vapor circulation.
(16) Influence of one over the other.
(17) Merits of mechanical and natural circulation for the problem involved.
(18) Composition of solution to be treated.
(19) Initial temperature of same.
(20) Maximum temperature to which it may be heated.
(21) Initial density.
(22) Final density.
(23) Specific heat of solution at various densities.
(24) Viscosity at various densities and temperatures.
(25) Rise in boiling point at various densities.
(26) Surface tension under various conditions.
(27) Latent heat of solution under varying conditions.
(28) Scale-forming constituents and their characteristics.
(29) Best method of removing same.

(43) Cycle by which evaporator will operate.

There are other variables not mentioned here, but the above list will suffice to show that proper study of such problems requires laborious and painstaking work.

Importance of Temperature and Humidity Conditions in Factories

The Bureau of Mines, in co-operation with the United States Public Health Service and the Society of Heating and Ventilating Engineers, is engaged in a study of the relative importance and correct correlation of the many individual factors concerned in the problem of the physiological effects of different conditions of temperature, humidity and air motion. A special room has been constructed for this purpose at the Pittsburgh station in which the air conditions are controlled by apparatus outside the chamber and entirely separate from it. A comprehensive program, which includes a quantitative study of a considerable number of bodily functions, is being carried out.

The work of the investigators has not yet been completed, but enough has been done to demonstrate the importance of determining the physiological reactions to environment as a measurement of the harmful effects of heat and humidity, and to show that feelings of discomfort as a standard of measurement cannot be depended upon because there is a certain adaptation of the sense organs to an unchanging environment, and individuals differ in their sense reactions.

Mineral Filler Investigation

In the course of the investigation of mineral fillers being made by W. M. Weigel, mineral technologist, at the Southern experiment station of the Bureau of Mines, Birmingham-Tuscaloosa, Ala., three special problems have been studied: Determination of grain size of fillers, involving elutriation and microscopic measurement, followed by methods of calculation; the effect of heat-treatment on the physical properties of white clays with respect to their use as fillers; and the utilization of Alabama flake graphite. The size of particle is a basic property of fillers upon which many of the other physical properties depend, consequently considerable work is being done in this direction. Work has been completed on the study of the effect of heat-treatment on the physical properties of clays. The lubrication tests on graphite were satisfactory, while results of the molding tests were negative. Experiments in the use of graphite as a remover of boiler scale were only partly satisfactory, being partly negative. A special investigation has been made of a series of clays from central Georgia and western Georgia with respect to their value as fillers.

Thermal Curves for Chromium-Vanadium Steels

AN EXTENDED REPORT of some co-operative work done by the Bureau of Standards and the Fixed Nitrogen Research Laboratory of the Department of Agriculture on chromium-vanadium steels was made by J. S. Vanick and W. W. Sveshnikoff, speaking before the Detroit meeting of the American Society for Steel Treating. First the thermal curves of plain carbon steels were compared with a series of steels containing Cr. 1.0, V 0.18, Mn 0.65 and Si 0.25, with carbon varying from 0.16 to 1.16. One such comparison follows:

	Ac_1	Ac_2	Ac_3	Ar_1	Ar_3
Plain 0.34 C steel	734	764	787	680	750
0.30 Cr-V steel	768	764	807	697*	747*
0.30 Cr-V steel	..	..	..	709†	768†

*Cooled from 975 deg. C.
†Cooled from 852 deg. C.

Ac_1 and Ac_3 temperatures are raised by chromium, but the latter is lowered by the increasing carbon; the two points merge at about 760 deg. C. with 0.60 C (1.0 Cr, 0.18 V). As shown, Ac_1 is above Ac_2 for the low-carbon steels of this series, so the magnetic point cannot be used for hardening. An increase in the temperature from which the piece is cooled (T_{max}) is seen to lower Ar_1 and Ar_3, even in this low alloy.

Ar_1 point, however, is reasonably constant in position, and its intensity varies with the carbon content, therefore this arrest is probably due to carbon alone. Ac_2 is very difficult to determine from the thermal curves, but shows very plainly as a large increase in hardness when the quenching temperature passes that point.

A series of steels varying in vanadium content from 0.02 to 0.58 and containing C 0.35, Mn 0.50, Si 0.23 and Cr 1.05 were examined. The influence of V in these analyses is slight. Ac_1 and Ar_1 are both raised about 5 deg. C. for each 0.10 per cent V. Ar_3 is slightly raised by V; but 0.01 per cent carbon will overbalance seven times as much V. Vanadium is thought to enter a complex carbide for three reasons: (1) The intensity of Ar_1 varies as the carbon content; (2) T_{max} has no effect upon the Ar points as in Cr steels; and (3) the hardness vs. quenching temperature curves are similar to those of plain carbon steels, and a sample quenched from above Ac_3 shows no excess constituent.

Several chromium steels containing from 0 to 2½ per cent Cr and 0.35 C, 0.50 Mn, 0.2 Si and 0 to 0.3 V were investigated, together with three similar ones containing 7.7, 14.4 and 21 per cent Cr, respectively. As noted early in the paper, small amounts of Cr raise Ac_1; at 0.75 per cent Cr it merges with Ac_2 and at 3.1 per cent with Ac_3. Up to 7.7 Cr, however, Ac_2 remains unchanged, and therefore thus far there seems to be no free chromium in the annealed steel.[1] Beyond that point Ac_2 drops rapidly, reaching 675 deg. C. at 21 per cent Cr, an evidence that these high alloys have chromium dissolved in ferrite. Chromium carbide hinders the normal solubility of carbon in austenite, and also impedes the $\alpha \rightarrow \gamma$ change, thus raising both Ac_1 and Ac_3.

When cooling these low-chromium steels from 975 deg. C. at the rate of 7 seconds per deg. C., Ar_3 gradually lowers and Ar_1 gradually raises, the two merging at 2½ per cent Cr at about 710 deg. C.[2]

[1]The analysis 7.7 per cent Cr, 0.37 per cent C agrees very closely to the formula $Fe_3C.Cr_3C$ suggested by Murakami.

[2]At a hypothetical zero cooling rate, $A_{1,3}$ would occur at about 3 per cent Cr in steels containing 0.30 per cent C, a ratio corresponding to Edwards' proposed Cr_5C_2.

High-chromium steels show a "split" transformation on slow cooling from 975 deg. C., the upper portion being called Ar′ and the lower Ar″, as is shown in the following table:

Cr Content	Ar′	Ar″
7.7 per cent	small, at 701	small, at 395
14 per cent	very small, at 695	large, at 387
21 per cent	none[3]	feeble, at 350 to 170

Such effects of increased chromium can be produced to a degree in a single steel by increasing the rate of cooling, or by increasing T_{max}. Ar″ is exceedingly sensitive to changes in the cooling rate, producing corresponding changes in the structure and hardness.

These facts are explained by the supposition that the steel above Ac_1 contains chromium and carbon in solid solution, and upon cooling, the chromium retards the re-formation and accumulation of the carbides, stable at lower temperature. Furthermore, dissociation of carbides proceeds continuously upon heating past Ac_1, all free constituent disappearing from the microscopic field when the 7.7 Cr steel is heated to 950 deg. C. Increasing amounts of free Cr as T_{max} increases cause a strengthening of Ar″; more uniform distribution of the materials in solid solution at the high temperatures is thought by the authors to be responsible for the coincident suppression of Ar′. At maximum dispersion, Ar′ should vanish and Ar″ be unaffected by further superheating.

Quenching the 7.7 or 14.4 per cent Cr steels from 1,000 deg. C. does not suppress Ar″, so the microstructure is coarse-grained martensite. Cooling to above A′ and quenching give fine-grained martensite plus small globules of carbide, and a lower hardness. If the mass is cooled to within Ar′ and quenched, there appear minute black specks of troostite throughout the ground mass. Cooling to below Ar′ and quenching give a coarse-grained martensite outlined by thick troostite meshes. Quenched from within Ar″ shows some martensite grains, but distinct granulation in the troostite area. Slow cooling gives sheroidized carbides. Of course, since all these structures are unstable, with the exception of the latter, they depend upon the conditions existing at the time of their formation.

In explanation of the cooling curves shown and the structures obtained, the authors think that Ar″ is the suppressed $Ar_{3,1}$ transformation. The fact that a high-chromium steel showing only Ar″ may give martensite as a sole constituent upon quenching supports the French view that Ar″ is the lowered Ar_3 change (γ to α iron). The degree to which the Ar″ transformation has progressed marks the degree of martensitization of the austenite.

On the other hand, a split transformation (Ar′; Ar″) is invariably accompanied by the appearance of troostite in the structure.

The authors show that where Ar″ occurs with Ar′ the former transformation is accompanied by the coalescence of carbides in the troostitic meshes. This leads them to the conclusion that when Ar′ and Ar″ occur, the latter is a combination of $Ar_{3,2}$ and Ar_1. In such cases it is thought that $Ar_{3,2}$ proceeds to completion in the grain-like, austenomartensitic areas, while Ar_1, marked by the coalescence of the carbides, proceeds simultaneously in the troostitic meshes. Troostite actually granulates before the matrix changes, therefore Ar_1 proceeds to completion at Ar″.

[3]A feeble A_2 point shown at 675 deg. C.

The Colloid Mill and The Ultra-Filter Press

The Impact and Friction Types of Colloid Mills—Various Proved and Suggested Uses for These Mills—The Ultra-Filter Press—Its Use With the Colloid Mill and Some Other Applications

By A. W. Kenney

Experimental Station, E. I. du Pont de Nemours & Co., Wilmington, Del.

IN SPITE of the constantly increasing appreciation of the importance of colloids in the industries there has not been any generally applicable industrial process for producing ordinarily massive substances in the colloidal state. Within the last 2½ years, however, Hermann Plauson, a Russian physical chemist, and Berthold Block, a German engineer, have published a series of articles* on a "colloid mill" which they have developed; and although our information in regard to this apparatus is limited, its promise is so great as to deserve our attention. By means of this colloid mill such various substances as coal, wood, phosphate rock and rubber can be reduced mechanically to stable colloidal suspensions, and applications of a novel nature have been developed in many unrelated processes.

The mill is the culmination of work carried on by Plauson for nearly 10 years, and its performance to date has demonstrated its remarkable possibilities in many lines. A surprisingly large number of technical problems have been attacked with its assistance, and the results claimed deserve the careful consideration of American chemists and engineers.

Still in the Development Stage

It must be clearly understood at the outset that sufficient data are not yet available to enable the commercial value of this new equipment to be estimated accurately. The inventors are naturally enthusiastic in their claims; and there is much in the results already obtained to justify their enthusiasm. Although the processes described may be carried out as they say, there are still such undetermined factors as power costs, production capacity and depreciation. These, as well as the qualitative results, will determine the economic value of each projected process. It must also be stated that not all the claims for the mill appear to be well founded. With the exception of patents and a few articles by other writers, our only source of information are the publications of the inventors themselves in German magazines.

Plauson has attempted to protect his interests in the various developments with which he is concerned by applying freely for patents in various countries—Germany, Great Britain, France and the United States. By no means all of these patents have been granted at this date, and, as Frydlender suggests, it is somewhat questionable whether the mill itself can be patented. Many of its applications are, however, protected. The inventor's policy has been to sell territorial rights to the exploitation of his patents, and it is reported that arrangements are already complete for most of the industrial countries of the world. In the United States, the rights are owned by the Newport Co., Milwaukee, Wis.

*See bibliography at end of article.

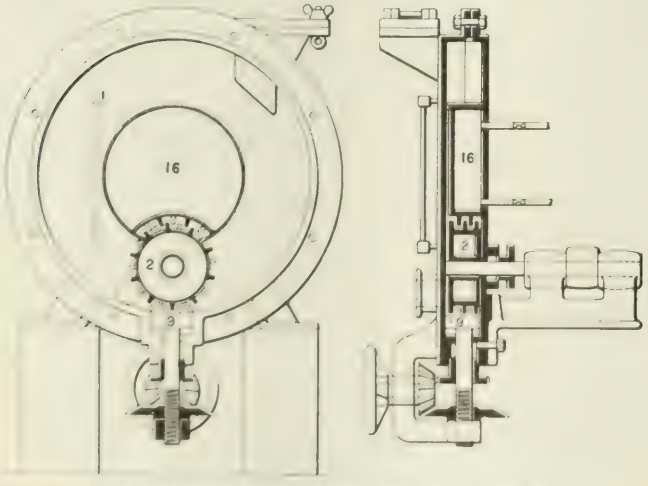

FIG. 1. THE IMPACT TYPE OF COLLOID MILL

The Impact Type of Colloid Mill

Plauson believed that if any massive materials could be subdivided to particles between 1 and 0.01 microns in diameter and suspended in a non-conducting medium, colloidal solutions would result. With this in mind, he studied the effectiveness of the various grinding and crushing appliances in use and singled out impact mills as the most promising type for development. In the colloid mill he utilizes two principles which his work indicates are fundamental. First, in order to obtain extremely fine disintegration it is necessary to have the crushing force applied at high potential. For instance, if we consider the action of a hammer and anvil as exemplifying the process taking place, Plauson has determined that a hammer applied at the highest possible velocity is more effective than a heavy, slowly-moving one. The mill, therefore, operates at high speed. The second principle is that it is essential to disintegrate in a liquid medium, which serves to propagate the force of the blow in the same way that seawater transmits the explosive force of a depth bomb to the submarine which is to be destroyed. Accordingly, the charge fed to the mill consists either of two or more liquids or of a finely ground solid mixed with a considerable excess of the liquid used as dispersion medium.

How the Impact Mill Operates

Plauson's first "colloid mill" is illustrated in the accompanying cut, Fig. 1. This represents an early form of the mill, and it very probably differs from the latest improved designs, although no later description of this type has been published. In this mill the toothed cylinder 2 rotates at very high speed, causing the teeth to beat the liquid charge and to throw it violently against the toothed resistance 9. The high speeds employed do not permit the liquid to flow around the teeth, so it is hammered just as when the surface of water is struck with the flat of the hand: and the force

of the blows which it receives is transmitted to the suspended particles, causing them to disintegrate. The electrical and heat effects produced by the violent impacts also tend to cause disintegration. The centrifugal action of the beater keeps the liquid at the circumference of the container and brings about a continuous circulation, so that new particles are constantly being subjected to the beater action. In order to control conditions more exactly, the mill is equipped with means for heating or cooling the charge as desired, by circulating water through the tank 16.

High Speed in the Impact Mill

The use of very high speeds is essential to successful operation. Peripheral speeds as high as 200 meters per second have been attained in a specially designed unit where the mill is driven by a direct-connected steam turbine. The corresponding rotating speed is 12,000 r.p.m., so the rotating beater must have a diameter of about 32 cm., about one-third that of the earlier mills described. The method of applying the power to drive mills at such speeds is in itself a problem. The direct turbine-driven unit appears to be the best design so far developed; but stepping-up gears specially designed for the purpose have been used for speeds around 6,000 r.p.m.; and direct drive by electric motor, or belt drive can be used for speeds not greatly in excess of 3,000 r.p.m.

The quantitative effect of speed on the size of particle obtainable is illustrated by the following figures cited by Plauson. If the peripheral speed is less than 10 meters per second, no better effect is obtained than by grinding in air (particles 0.001 mm. in size under best conditions). At 20 meters per second, an improvement is perceptible, and particles 0.0003 mm. in size are obtained; at 30 meters per second, particles of 0.0001 mm. are produced; and at 40 meters per second, true colloidal solutions. Higher speeds are actually used in order to accelerate the action.

The Friction Type of Colloid Mill

It is obvious that the use of such high speeds as Plauson recommends (peripheral speeds of 1,000 meters per second are mentioned in some of his patent claims) introduces difficulties. The suggestion that the speeds of the moving members might be reduced by having adjacent parts rotate in opposite directions is a natural one and led to the development of another type of colloid mill. In this type, two grinding surfaces brought very near together are rotated at high speeds in opposite directions. This design is illustrated diagrammatically in Fig. 2.

The solid material to be ground (suspended in liquid as before) is forced axially under pressure into the space between the rotating disks 59 and 62, and after being subjected to the grinding or rubbing action is thrown into the chamber 64, from which it flows out through the outlet 65. The pressure between the disks is regulated by the lever 50 and the adjustable weight 51.

Where the Friction Mill Should Be Used

These two colloid mills are adapted to somewhat different uses, though it is not always clear to which type reference is made in accounts of the various applications. The impact type of mill is the one first developed by Plauson, and with it he was able to achieve many novel results with varied materials. The friction type of mill is apparently a later development, though less original in design. According to the inventor, it is the one better adapted to making colloidal solutions from massive, non-colloidal material. The impact mill, on the other hand, is better adapted for use with emulsifiable liquids or naturally occurring colloids such as gelatine, rubber, gums, etc. It can also be used on solid material, but apparently the high speeds necessary for its effective operation on such material offer difficulties of design or are not economical. Indeed, when Plauson's early articles are considered, it may be suspected that the development of the friction mill was due to the fact that the impact type did not come fully up to his expectations.

The Technique of Making Colloidal Solutions

Working with the mills just described, Plauson obtained many interesting results, some of which could have been predicted from our knowledge of colloids. As already mentioned, Plauson considered the manufacture of colloids to be merely a mechanical process of disintegration in a non-conducting liquid medium. His early experiments show how very important it is that the liquid medium actually be non-conducting. The presence of very small amounts even of weak electrolytes, formed by hydrolysis from the material under treatment, renders it impossible to obtain particles sufficiently small to form a colloidal solution. The most rigid precautions have to be taken to preclude the presence of electrolytes.

Another interesting phenomenon which Plauson observed is that of saturation. He found that it is not possible to take any two substances, say *A* and *B*, in any proportions whatever and by means of the mill

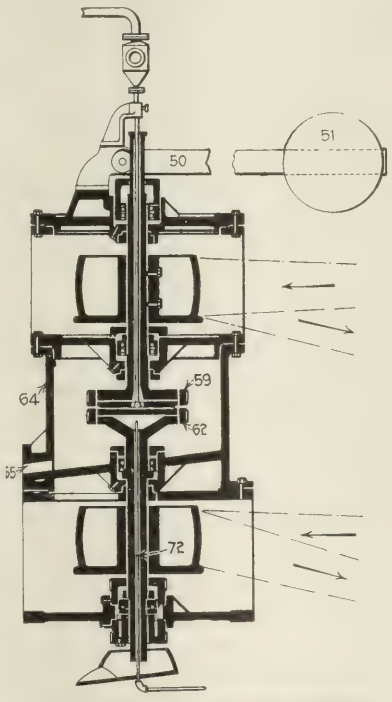

FIG. 2—THE FRICTION TYPE OF COLLOID MILL

produce a colloidal solution of that composition. Only a definite concentration of *A* in *B* can be attained; and if there is an excess of *A*, another phase forms, a solution of *B* in *A*. Plauson calls these colloidal solutions, to which no more of the dispersed phase can be added, saturated solutions in analogy to the solubility relations

of solids in liquids. No amount of treatment in the colloid mill serves to produce solutions of higher concentration than these saturation values. It was found, moreover, that this relationship is very specific, depending on the nature of the dispersed phase and of the dispersion medium. As illustrations the following figures may be cited showing the saturation concentration of copal in various dispersion media:

	Per Cent		Per Cent
Benzene	1.8	Glycerine	2.8+
Water	2.2	Amyl alcohol	5.0+

It may be noted that Plauson found thus two difficulties to be overcome in technical applications of his mill: one the deleterious effect of even small amounts of electrolytes, and the other the formation of saturated solutions, many of such low concentration as to be of little commercial value. In the use of "dispersors" Plauson found a means of overcoming partly both of these difficulties. He found that small amounts of "dispersors" (protective colloids or, as we should more commonly say, peptizing agents) added to the mixtures to be treated neutralize to a large extent the influence of weak electrolytes in small concentration, and also enable solutions of much higher concentration to be produced.

These dispersors, to use Plauson's term, are of the utmost technical importance. They are used in almost every commercial application, and the selection of a properly functioning dispersor may be the critical point in many technical problems. Several illustrations of the use of dispersors may be given. Glue (partly decomposed with alkali) is added in manufacturing colloidal solutions of coal. Tannin accelerates the disintegration of graphite, and soap solution that of talc. Sugar is used in grinding mineral colors, and glycerine in making colloidal solutions of iodine, mercury and sulphur.

The action of the dispersor is specific, as may be seen from these illustrations. Plauson distinguishes three classes of dispersors: (1) substances capable of dissolving the material to be dispersed (without forming electrolytes)—for example, alcohol in the dispersion of phenol condensation products in benzene or water; (2) substances which, with the material to be dispersed, form reactive chemical compounds with colloidal properties—e.g., potash with fats and oils; (3) substances which are capable of forming complex compounds with chemically indifferent substances, but cannot form free ions. Tannic acid used with coal or carbon is an instance of this class.

Use of the Ultra-Filter Press

Another way out of the difficulties which arise from too dilute solutions is by use of the ultra-filter press invented by Plauson. By means of this press thick colloidal pastes may be obtained directly from dilute solutions simply and cheaply. A description of this equipment is given at the end of this article. The colloid mills and the ultra-filter press are complementary, for the mills could not realize their full possibilities without the aid of the press in concentrating the dilute solutions produced. Where it is desired to disperse a substance completely, the procedure followed is to treat it with a dispersion medium in the mill until a satisfactory colloidal solution is obtained. Ordinarily only a part of the material will be colloided. The solution is separated from the non-colloidal residue by settling or ordinary filtration and the residue returned to the mill for further treatment. The dispersion medium is recovered from the solution by filtration in the ultra-filter press, and the dispersed material, on the other hand, is ejected from the press in the form of a viscous solution or paste.

Industrial Applications of the Colloid Mills

The many applications already devised for the mills may be classified according to the nature of the action effected. The mill may be used simply for stirring—for example, in dissolving salts. Plauson claims that it is very effective in such work; and it probably is, though hardly economical. In some instances, the mills are used merely to produce very fine grinding, as in the case of pigments, or to produce suspensions or emulsions; in others, they are used for the extraction by selective emulsification of one or more constituents from a mixture; it has, for instance, been used for recovering oil from shale. There are also many processes where the mills are used to induce or accelerate chemical reactions.

As an instance of the use of the mills merely to produce an extremely finely divided product, the disintegration of phosphate rock for fertilizer may be mentioned. It is claimed that the rock can be reduced to so fine a powder that it is directly assimilable by plants without being treated with sulphuric acid. It is also stated that in compounding rubber the mill yields products of exceptional excellence owing to the fineness of disintegration and the homogeneity of the resulting mix. The grinding of pigments in the mill—for example, ultramarines—greatly increases the brilliancy of hue. Blanc fixe can be made merely by milling barytes.

Making Plastic Cellulose

The manufacture of plastic cellulose is another accomplishment of the colloid mill. Wood is reduced by grinding to a fine powder and the finest particles are separated by air and mixed with a large volume of water to which a small amount of alkali or other dispersor is added. After treatment in the mill, the resulting colloidal solution is precipitated with acid and the cellulose gel carefully washed free of salts and dried *in vacuo* to prevent the action of air. The powdered or gel cellulose thus obtained may be molded hot, and the resultant product possesses excellent mechanical properties as well as high di-electric strength. Its tensile strength is 300 to 500 kg. per square centimeter, it machines well, and a plate 3.5 mm. thick will withstand a potential of 55,000 volts.

The ability to make stable solutions, regardless of the solubility relationships of the different constituents, enables lacquers and varnishes of an entirely new type to be developed. The desired gums can be dispersed in any cheap solvent by means of the colloid mill. While a variety of such varnishes has been prepared, their properties have not been reported in any detail. The possibility is, however, a very attractive one.

Making Emulsions

In making emulsions of oil and water, Plauson believes that he has developed a new type of lubricant which, while very effective, is extremely economical on account

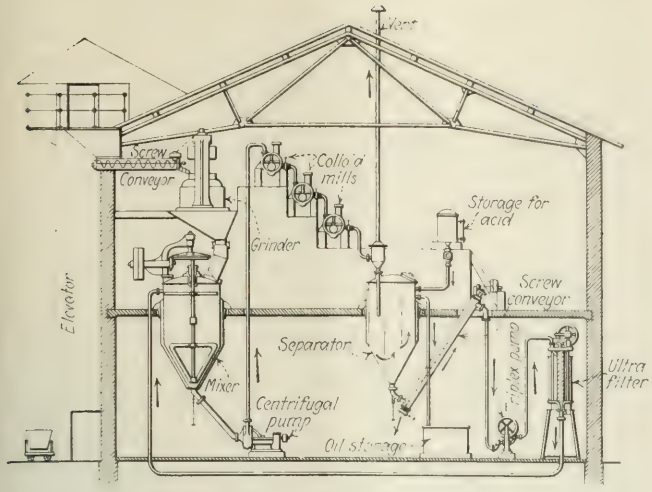

FIG. 3—PLANT FOR OBTAINING NAPHTHA FROM BITUMINOUS SHALE

of the considerable water content. If, for example, a mixture of two parts of oil and two to three parts of water are emulsified, a thick, pasty grease is obtained. It is possible to add to this paste solid lubricants such as graphite, talc, etc., and the lubricating mixtures thus formed carry heavy loads very well. Plauson points out that such lubricants are perfectly neutral and asserts that the emulsions are very stable. In Germany, where oils and fats are scarce, their economic advantages will be much more appreciated than they would be here.

One of the industrial applications of the mill for which the inventor feels there is exceptional promise is the making of "liquid coal," a colloidal suspension of coal in fuel oil. Thirty to forty parts of powdered coal is mixed with seventy to sixty parts of fuel oil, a suitable dispersor is added, and the mixture treated in the mill at high speeds ½ to 3 hours. The resultant sirupy liquid can be burned like other liquid fuels, but has, of course, a higher heating value per unit volume, which makes it especially desirable for marine work. As much as 15 per cent water can be added to the mixture without causing precipitation of the coal.

Separation by Colloidal Mill

In many instances Plauson has used the colloid mills for the separation of difficultly separable mixtures by colloiding one of the constituents. A process which he says was received very favorably in this country (presumably on the experimental scale) is the recovery of naphtha from petroleum slimes or shales. Some of these contain so large a portion of earthy material that separation by distillation is not feasible. Plauson proposes, therefore, to treat the finely ground shale in the mill with a large excess of water, with which the naphtha forms an emulsion. From the resulting mixture the mud settles rapidly on standing, permitting the emulsion to be drawn off, and the naphtha and water are then separated by heating. It is claimed that from an original content of 24.6 per cent oil, a yield of 19.8 per cent was obtained, and further oil was extracted by subsequent treatment. A diagram of a plant operating on a slight modification of this process is shown in Fig. 3. The shale is ground, mixed with water, and fed to three colloid mills operating in series. Acid is used to break up the resultant oil-water emulsion, and the oil is separated by gravity. The mud and water are then conveyed to a filter press and the water, still containing some oil, is returned to the system. This method is, of course, applicable only to those shales, well known both in this country and in Russia, from which the oil can be extracted with solvents.

Some Ill-Founded Claims

An instance in which the claims for the colloid mill appear to be ill-founded is in the manufacture of colloidal resins. It was stated in one of Plauson's early contributions that by treating crude domestic (German) resins in the mill a colloidal suspension of the true resin could be obtained very economically. In fact, a company was organized to exploit these colloidal resins. Their success must have been very limited, however, since a correspondent of the *Seifensieder-Zeitung* pointed out very emphatically that such resins were by no means pure; that in addition to large amounts of water which had been incorporated with them, the original impurities were still present; and that, due to the treatment in the mill, these impurities were so thoroughly incorporated that no economical method was available for purifying the product.

This case reminds us that the colloid mill cannot be a panacea for all industrial ills. In the enthusiasm of discovery, claims are doubtless made which will not be substantiated by experience. While there are many cases where separation can be effected, as in the extraction of oil from petroleum shales, or of vegetable oils from oil-cake, there are also many cases where treatment in the mill will serve to render the impurities much more difficultly removable than before. It must be realized, however, that mistaken applications should not prevent the real merits of the mill from being appreciated.

Accelerating Chemical Action by Use of Colloidal Mill

There are many cases in which the mill is used to accelerate chemical reactions. One of the more recent of these is in the making of viscose for artificial silk, plastics, etc., and this is an excellent example of the use of the mill for such purposes. By treating the cellulose first in the colloid mill, it is reduced to the colloidal state, and is then in a condition to react directly with the theoretical amount of alkali to form the monosodium derivative. This reaction is carried out in the mill, as well as the following step in which the carbon bisulphide enters into the reaction. For this process the following advantages are claimed: (1) The action of the theoretical quantity of alkali is possible at ordinary temperatures. (2) The reaction time is considerably shortened, so there is less hydration and decomposition of the cellulose by the alkali and consequently less contamination with byproducts. (3) No treatment with acid is necessary at any stage. (4) Less carbon bisulphide is used, and the reaction proceeds very smothly. (5) The viscose solution obtained is very pure. (6) A long ripening of the viscose is not necessary. It can usually be used in a few hours. (7) The silk produced from the viscose is of higher quality and is produced at less expense.

In the cuprammonium process the colloid mill can be used in a similar manner.

The reduction of the cellulose particles to colloid size makes them, of course, very susceptible to any chemical action, and the saccharification of cellulose as a pre-

liminary step in the manufacture of alcohol from wood-waste is very greatly accelerated by using the cellulose in this form.

Hydrogenation of Oils

A quite different application of the mill in accelerating chemical reactions is in the hydrogenation of oils. The very thorough mixing of the hydrogen and the oils which may be obtained by this means greatly increases the velocity of reaction. Plauson found, too, that instead of adding a catalyzer of powdered nickel to the oil before hydrogenation, it was sufficient if the parts of the mill in contact with the oil were covered with nickel. This proved to be a convenient and effective method of operation.

Still another use of the mill in this field is in the soap industry. By treating the fats and oils with caustic alkali in the mill, the reaction time is greatly

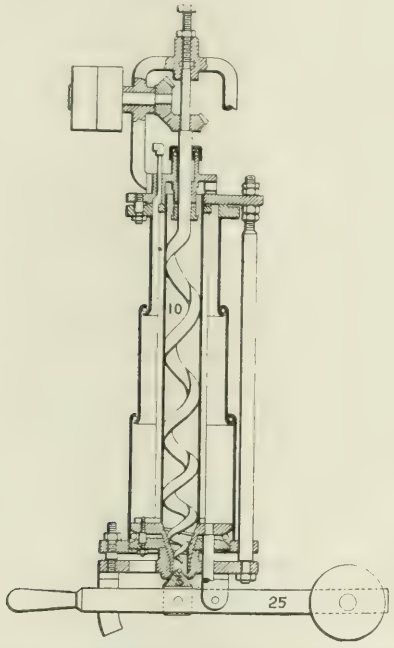

FIG. 4—THE ULTRA-FILTER PRESS

reduced and a very uniform product is secured. Little supervision is necessary, and one man can run several mills, so the operating expense is considerably reduced.

The Ultra-Filter Press

Reference has already been made to the ultra-filter press. Its design is shown diagrammatically in Fig. 4. The outside is constructed with telescopic joints. The charge is pumped in at the top and the solids are forced constantly downward by the screw 10 till discharged through the conical joint 3. The pressure required to expel this material is regulated by the lever 25 and an adjustable weight. The filtering surface is the cylinder surrounding the screw 10 and consists of several superimposed perforated metal sheets, the pressure between which may be regulated by means of a screw. The particles of precipitate gradually obstruct the small interstices formed by these sheets and thus build up a cake which effectually prevents the passage of further colloidal particles, but which does permit the liquid to pass through. In some cases a preliminary cake may be built up of plaster of paris, or asbestos, or similar materials. The revolving screw maintains a constant thickness of filtering material on the wall so that the conditions of filtration are uniform; and the colloid becomes more and more pasty as it descends in the press until it is discharged. The filtrate obtained is said to be exceptionally clear.

A number of advantages are claimed for this design. The press is continuous in operation. It uses no filter cloth. It operates under high pressures (as high as 200 atm.) or it may be used as a vacuum filter. It is easily washed. The pore size and thickness of cake are adjustable.

Plauson has also constructed another type of filter surface using instead of the wire mesh fabrics a coil of fine wire outside a coarsely perforated metal cylinder. In that case the colloidal particles gradually plug the spiral passages along which the liquid escapes and thus a filtering membrane is formed as before. If the wires used are wound with cotton, or paper, and the like, an especially effective filter is obtained.

Applications of These New Filter Presses

The ultra-filter press has found many industrial applications apart from its use in conjunction with the mills. In the beet sugar industry, for instance, the juice is subjected at present to a purification process which consists in treating it with lime and subsequently charging the solution with carbon dioxide. The precipitate, which in addition to calcium carbonate contains many of the organic impurities, is removed by filtration. This whole process, which requires considerable time and equipment, may be eliminated by filtering the juice directly through the ultra-filter press—previously adding only a small amount of lime to decompose non-sugar substances.

In the ceramic industries, also, the filter press has a large field in the dehydration of clays.

Another use of the ultra-filter press is in the crushing of oil seeds and in the purification of oils. The oil seeds after the usual cooking may be treated directly in the press, which operates like an expeller press. The oil, being thus simultaneously subjected to a filtration, leaves the press clear and free from albuminous matter. Crude oils may readily be purified by treatment with barium hydroxide solution in the colloid mill and subsequent filtration in the ultra-filter press with a pore size of 0.4 to 0.1 μ. By this means, not only the coarser contaminations such as albumins are removed, but also the coloring material; so that a pure, clear oil flows out. The use of the filter press in conjunction with the mill has also proved effective in removing oil from substances containing it such as anthracene, paraffine, etc.

By making the pores sufficiently fine, it is even possible to prevent the passage of bacteria, and it is suggested that the filter may find application in water purification, where its compactness will be an advantage over the extensive filter beds now in use.

Conclusion

The various applications cited above are by no means all those mentioned in the articles already published; and they certainly do not exhaust the possibilities of the new machines described. Very possibly many of the processes described may not prove to be commercially successful, but certainly this new technique for producing colloids on an industrial scale offers an opportunity for the solution of many difficulties and opens up

possibilities of a varied nature to the chemical technologist.

Small Electric Furnaces for Experimental Heats

During the war a large number of special alloys were tested by various agencies to determine their fitness for munitions. One series, made by H. W. Gillett and E. L. Mack,[1] was for determining their resistance to erosion by hot explosive gases. For this purpose, a sound ingot weighing 30 lb. was sufficient.

A small single-phase direct-arc furnace was first tried. The iron shell 11x15x13 in. high was lined with magnesite brick 1¼ in. thick; the bottom rammed up with magnesite and water glass, and the top covered with a zirkite brick slab. Side walls were water-cooled. Graphite electrodes, 2 in. in diameter, were set 2 in. apart, and carried 500 to 700 amp. at 75 to 90 volts. At first an iron mold was filled direct from the furnace. This practice always resulted in gassy steel, and a preheated ladle was later used. Sound ingots resulted from a lower pouring temperature. The furnace was unsatisfactory, however, because from 0.2 to 0.6 lb. graphite was taken from the electrodes in restarting the arc during melting down. With such a small charge, this was responsible for wide variations in the carbon content of the resulting steel. The thin side walls also spalled badly—zirkite brick did better, lasting fourteen heats.

A cylindrical furnace, much like a rocking brass furnace,[2] was then built, and proved very satisfactory for making about 200 intermittent heats of high-alloy steels. From operating experience, the authors recommended the following: The furnace should have a steel shell, 32½ in. in diameter and 45 in. long. The outer lining should be 1 in. of Sil-O-Cel or some similar reliable low-temperature insulator; a second layer 2½ in. thick of high-grade aluminous (corundite) firebrick; the third layer consisting of 4-in. magnesite brick in the lower or hearth half, and bare Carbofrax in the roof. If the furnace is to do refining, the hearth should then be covered with electrically sintered, dextrin-bonded magnesia. If a mere series of similar melts is to be made, the hearth is preferably lined with 1 to 2 in. of alundum cement, rammed in in layers, each layer being dried thoroughly with a gas flame and moistened with a thin wash of alundum before a fresh layer is placed and dried.

The furnace ends should be built of magnesite blocks with a total thickness of 15 in., and the corners filled with alundum so that the hearth is a roughly spherical chamber, 14 in. in diameter.

Such a thick end wall forms an admirable support for the electrodes. There are to be 2 in. graphite rods, 40 to 48 in. long. Split bronze castings may be used for connectors, good contact being insured by wrapping the carbon with copper gauze. When the electrode shortens so the connection becomes hot, it may be covered with asbestos cloth kept wet by a water drip. Adjustment may be done by hand. When charging or repairing the lining, the electrode hole should be punched with a 2⅜-in. steel bar.

A 12-in. square opening in the shell forms a charging and pouring opening. It is to be closed by a plug of carborundum brick, cemented and covered with alundum cement. The door is iron bound and held in place by keying to eye-bolts attached to the furnace shell. After charging, the door and electrode openings should be luted with alundum cement, and as the furnace heats up, any cracks are brushed with thin wash. In this manner the furnace is kept air-tight.

The entire furnace should be bound with two iron hoops, running on trunnions. Iron levers attached to the side permit rotation by hand when pouring and patching the lining. During melting the furnace is stationary.

Such a furnace takes from 60 to 70 minutes to preheat the lining. A current of 500 to 750 amp. at 60 to 90 volts will be required. After charging and closing the furnace, it is run until a calculated amount of power is put in, as experience with similar conditions requires (40 to 50 kw.-hr. for a 50-lb. charge).

Molybdenum and Cerium Alloy Steels

In the study of molybdenum and cerium alloy steels at the Ithaca, N. Y., field office of the Bureau of Mines, endurance tests on bars taken both with and across the direction of rolling show that the relationship between endurance and tensile strength (or hardness), which holds fairly closely for longitudinal bars, does not hold nearly as well on transverse bars. The endurance of transverse bars is lower, and the amount by which they are lower appears to depend primarily on the type, size, number and distribution of the non-metallic inclusions.

Cored Structure in Quenched Manganese Steel

By Sergius S. Beliaeff

FOR close examination a polished surface of steel is usually etched with an acid or some other solution to develop its structure. A number of different solutions are employed, depending on the alloy or steel used and the characteristic it is desired to study. But all those reagents could be divided into two groups. In Group I would be classed etching reagents for micro-examination—in other words, the examination of the structure of steel under high magnification (from 20 up to 1,000 times). Reagents in Group II are used for studies at low magnification, such as two or three diameters, or even at natural size with the naked eye. Sometimes very interesting results are obtained by using a reagent of Group I in parallel with those of Group II or of a deep pickling with acid.

An entirely different structure may be obtained from the same sample of manganese steel which has been etched with a reagent of Group I, by repolishing and etching with a reagent of Group II. For instance, Fig. 1 is cast manganese steel (C 1.25 and Mn 12.0 per cent), which has been quenched in water from 1,850 deg. F. and etched with 3 per cent nital. At 100 diameters it shows typical austenitic network structures, with inclusions of free manganiferous carbide. Fig. 2, on the other hand, is a photograph of the same surface after it has been repolished and etched with Le Chatelier's solution[1] No. 1. This shows typical dendritic structure.

Both photographs are practically of the same magnification, but their appearance is totally different; at first sight they have no relation whatsoever. But if a photograph is taken from the same specimen after double etching, but without repolishing between the nital and the cupric reagent, a close connection is found between the grain boundaries of austenite and dendrites.

The deposit of copper must be washed off with strong ammonia before photographing. This method of etching not only develops the grain of the alloy but even reveals non-homogeneity in the grain itself, showing that each dendrite forms a crystal, even after a quench from 1,850.

A sample of the same steel in its cast condition, etched with nital, has the same structure as Fig. 2, which was etched with copper solution after heat-treating. The typical dendritic structure of cast manganese steel, revealed by etching with nital, was apparently entirely changed by heat-treating into a network of austenitic grains. This is true as far as can be shown by etching with nitric acid, but by etching with Le Chatelier's solution or other reagent, each grain of austenite will be shown to contain many features of the original dendrite.

British Experiments in Enamel-Kiln Firing

A series of interesting experiments in connection with the insulation of enamel kilns has been carried out recently by a British firm, according to an article in the *Staffordshire Gazette*.

In enamel kilns, owing to the radiation of heat from the iron doors, difficulty is experienced in firing up the ware in front of the kiln, so that the custom is to fill the front with ware requiring slight firing as compared with the goods in the other parts of the kiln. The experiments have been directed toward preventing the loss of heat by radiation and obtaining uniformity of temperature throughout the kiln. It is stated that success in the experiments has been obtained by the firm after numerous attempts.

To prevent the radiation of heat, a mattress packed with blue asbestos fiber has been constructed on an iron frame to cover the kiln doors. In blue asbestos there is a stronger fiber and a better heat resistance, and it is claimed that this mattress retains practically all the heat that would otherwise be wasted in the kiln. Obviously this increases the temperature in the front of the kiln, and the ware in the front of the kiln can be fired just as in any other part. It is essential that the doors of the kiln should be lined with firebrick. This prevents damage being done to the mattress through the doors becoming too hot. The iron doors, of course, become much hotter than they do without the mattress, as a result of the heat being kept in by the mattress.

The apparatus is quite simple and inexpensive and is actually only an application of the asbestos covering of boilers and steam pipes in pottery ovens.

Ethylene From Trent Amalgams As a Source of Alcohol

By J. D. Davis
Research Chemist, Pittsburgh Experiment Station
U. S. Bureau of Mines

SIXTY YEARS AGO M. Berthelot found that ethylene could be selectively absorbed from gaseous mixtures by concentrated sulphuric acid and that the compound formed by the chemical union of the gas and acid was readily decomposed by heating with water, yielding ethyl alcohol. Only within the last few years has there been any attempt to make use of this discovery technically. Bury,[1] working in England at the Skinningrove Iron Works and on a commercial scale, developed a technical method for converting the ethylene of coke-oven gas into alcohol. With a gas containing less than 3 per cent of ethylene, he obtained a yield of 1.6 gal. of alcohol per ton of coal carbonized.

De Loisy[2] perfected a technical method for treatment of coke-oven gas for alcohol. Evidently this work was carried out on a semi-commercial scale. His method is based on the use of catalytic agents for hastening the absorption of ethylene by sulphuric acid. He uses part of the spent acid for drying the gases and part for the manufacture of ammonium sulphate. Excess acid is reconcentrated by waste heat. Others have worked on the problem, but so far there has been no large recovery of ethylene from coke-oven gases. The chief difficulty seems to lie in the low efficiency (about 50 per cent) of methods and the relatively low concentrations of ethylene in the gases treated. Gas from Trent amalgam[3] contains much larger percentages of ethylene than does coke-oven gas, as will presently be shown, and if it should ever prove practical to treat industrial gas for alcohol, this gas would offer attractive possibilities.

Method Used in Carbonizing Trent Amalgams

The method used here to carbonize the amalgams differs from any now used for the commercial carbonization of coal. In ordinary practice, coal charges are distilled at all temperatures from the decomposition point of the coal to the highest retort temperature, and no definite temperature can be fixed on as the temperature of distillation. With the method here used, the distillation range was made narrow. This was effected by feeding the charge regularly into a retort kept at constant temperature—that is, the predetermined distillation temperature. Distillations were conducted at temperatures 400, 500, 600, 700 and 800 deg. C., and the gases evolved were measured and analyzed. Samples of the coal and oil used to prepare the amalgams were distilled under the same conditions as were the amalgams for purposes of comparison.

TABLE I—ANALYSIS OF MATERIALS USED

Big Muddy Coal

	Per Cent
Moisture	5.78
Volatile matter	31.87
Fixed carbon	52.42
Ash	9.93
Total	100.00
Sulphur	1.28

Fractionation of the Navy Fuel Oil

Temperature Range, Deg. C.	Per Cent Distilling
130	First drop
130 to 225	1.1
225 to 250	4.83
250 to 275	14.25
275 to 300	20.10
300 to 325	21.70
325 to 350	30.90
Residue	5.82
Loss	1.31
Specific gravity of the oil at 20 deg. C.	0.868

Experimental Results

The materials used in the experiments were Illinois coal obtained from the Big Muddy Coal & Iron Co., Herrin, Ill., and an asphaltic-base fuel oil. An analysis of the coal is given in Table I, also the fractionation results for the oil. Table II gives the analyses of gases evolved from amalgam, coal and oil at temperatures 400, 500, 600, 700 and 800 deg. C., together with total yields of gas and light oils scrubbed from the gas. Results for the 700 deg. amalgam run are not reported, owing to the fact that precipitated carbon clogged the mains and rendered the gas samples taken of doubtful value.

In general, the oils give higher yields and richer gases; the amalgams give somewhat less gas of poorer quality; and the coals give the lowest yields and the poorest gas. It is an interesting fact that the run at 800 deg. C. (with continuous feed) gave almost as much

TABLE II—ANALYSES OF GASES FROM TRENT AMALGAMS, COAL AND OIL

[3] A paste consisting of approximately 2 parts finely pulverized coal and 1 part oil such as that obtained as a final product in the Trent process for cleaning coal. See Perrott, G. St. J., and Kinney, S. P., "The Use of Oil in Cleaning," *Chem. & Met.*, vol. 25, Aug. 3, 1921, p. 182.

gas for the amalgam as for the oil, and gave a gas of slightly better quality. At this temperature, it thus appears that Trent amalgam is just as good material for making commercial oil gas as the oil itself. The amalgam would of course be the cheaper, and further, it will be noted that under these conditions more oil was scrubbed from the amalgam gas than from the oil gas. Of course if a rich oil gas is wanted, the best procedure is to crack the straight oil at a lower temperature.

The percentages of oxygen-containing gases for the coals and amalgams are considered somewhat high. This is due partly to the method of feeding the retort and partly to the fact that the coal used was of high oxygen content. As for the first cause, the charge fed was finely divided, and must have carried into the retort a fair amount of adsorbed air.

Unsaturated Gases

The percentages of unsaturated gases are uniformly higher for the oil except with the run at 800 deg. C., where the amalgam gives the highest percentages. The coals give the lowest percentages of unsaturated gases, but slightly higher, perhaps, than would be obtained by commercial methods of carbonization. The amounts of these bodies found for the amalgams are intermediate between those for the oil and coal. Unsaturated gas is reported here as ethylene (C_2H_4), and it is probable that 95 per cent of it actually was ethylene. Especially is this true when it is considered that the gas had passed a charcoal scrubber, which would have a tendency to remove heavier gases.

Yields of Unsaturated Gases From Amalgams

Table III gives the yields of unsaturated gases from amalgams at the corresponding temperatures of distillation and their equivalents in alcohol, assuming complete recovery. Figs. 1 and 2 show the data graphically. As a basis of comparison of yields, we may take Bury's[4] figure of 1.6 gal. of absolute alcohol per ton of coal charged in byproduct ovens. Assuming a 50 per cent recovery, this would mean a possible yield of only 3.2 gal. of absolute alcohol per ton of coal from coke-oven gas, whereas from Trent gas there is possibly from 3 to 32 gal. per ton of amalgam charged. It would thus seem that Trent gas is ideal (second only to oil gas) for the application of an alcohol recovery process.

[4]Work cited.

TABLE III—YIELDS AND ALCOHOL EQUIVALENTS OF UNSATURATED GASES FROM AMALGAMS

Temp., Deg. C.	C_2H_4, Per Cent	Total Gas, Cu.Ft.	C_2H_4, Cu.Ft.	Alcohol Equiv. Gal. Per Ton
400	25.4	750	172	3.1
500	17.0	4,400	760	13.8
600	6.8	10,850	955	17.3
800	8.9	19,800	1,760	32.0

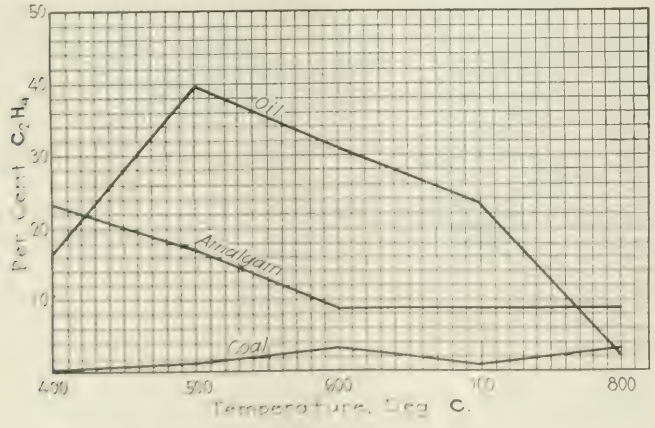

FIG. 1

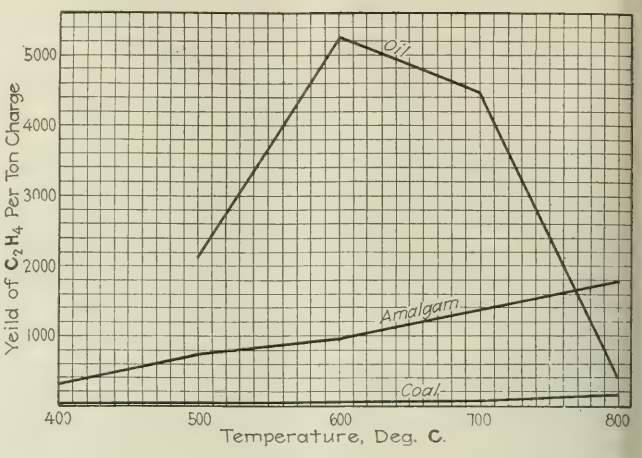

FIG. 2

Recovery of Ethylene as Alcohol

So far it has not been possible to recover from coke-oven gas more than 50 per cent of ethylene contained as alcohol, but it would undoubtedly be possible to improve this figure considerably by research. The problem offers possibilities, particularly in connection with the rich Trent gas. For example, De Loisy[5] found that he could increase considerably the speed of absorption of ethylene by sulphuric acid through the use of catalytic agents, and thereby increase the recovery of alcohol.

Loss of Heating Value Through Removal of Ethylene From Gases

Table IV shows that the loss of heating value suffered by Trent amalgam gages on removal of the ethylene is not an important consideration. They are rich gases to start with, and the removal of ethylene, although that gas has a high heating value, does not bring their heating value below that of the best industrial gases.

TABLE IV—EFFECT OF REMOVAL OF ETHYLENE ON THE HEATING VALUES OF TRENT AMALGAM GASES

Distillation Temp., Deg. C.	B.t.u. Per Cu.Ft. Raw Gas	B.t.u. Per Cu.Ft. Scrubbed Gas
400	1,000	798
500	936	795
600	726	639
800	757	671

It may be stated further that the ethylene in the composite gas has a market value much below that which it would have as pure gas. For example (see Table III), a 600 deg. distillation will yield 10,850 cu.ft. of composite gas, 955 cu.ft. of which is ethylene. The ethylene, if recovered commercially pure, would be worth 1 cent per cubic foot, or $9.55, whereas all the gas (at 50 cents per 1,000) would be worth about $5.40.

Conclusions

1. Trent amalgams yield gases intermediate between those from coal and oil in respect to both quantity and quality.

2. The high percentage of unsaturated gases from Trent amalgams offers a promising field for research.

Book Reviews

METHODS OF THE CHEMISTS OF THE UNITED STATES STEEL CORPORATION FOR THE SAMPLING AND ANALYSIS OF PIG IRON. 40 pages, paper covers. Published by the Carnegie Steel Co., Bureau of Instruction, Pittsburgh, Pa. Price $1, cash with order.

This is a revision of a similar pamphlet published 10 years ago for use of the chemists of constituent companies of the United States Steel Corporation. Such a manual is evidently most useful in enabling chemists in distant laboratories to reach comparable results on a shipment of iron—even though this iron is sent from one subsidiary to another—from the vest pocket to the hip pocket, as it were. The present booklet is the work of W. B. N. Hawk of Lorain, William Brady of South Chicago, and H. E. Campbell of Clairton.

Accurate and accepted methods of analysis are also essential to prevent disputes with outside buyers. For this reason the American Society for Testing Materials has adopted many standards for sampling and chemical analysis. Both publications agree, for instance, that Drown's method for silicon is to be used—the Carnegie pamphlet appears to describe the manipulations which would be adopted in repetitive routine work.

It is advised that molten iron be poured into a chill mold. Granulation by water cools too rapidly, the sample cannot be used for combined or graphitic carbon, and sulphur (by evolution) is always low. Sand-cast samples, on the other hand, are likely to be contaminated by molding sand. While it is recognized that volumetric or evolution methods for sulphur do not give exact figures (two gravimetric methods are described for accurate work) it is the only one known "which can be made within the time limits fixed upon the laboratory," and in careful hands and on steady production gives very good figures for control.

Combustion methods and apparatus for total carbon are given in great detail. Analysis for titanium and copper are added to those other elements ordinarily determined. E. E. THUM.

CLAY PRODUCTS CYCLOPEDIA. First annual edition, 1922. 252 pages, illustrated. Published by Industrial Publications, Inc., 407 South Dearborn St., Chicago, Ill. Price, $3.

It is the aim of this book to present in readily available form information and data pertaining to all phases of the clay products industry. In an industry with so many ramifications this represents no small undertaking, and the editors are to be congratulated upon the success of their labors. In what is termed the definition section, covering 121 pages, will be found condensed information regarding more than 10 materials, processes or types of equipment. The arrangement is alphabetical and each item is numbered. Many items are supplemented and treated more fully in a statistical section of 75 pages. While much of the material has been compiled from various sources, there is also a great deal which is original. As the editors are in constant touch with the industry through their publication *Brick and Clay Record*, the correctness of such material is assured.

Alphabetical arrangement always presents the disadvantage of scattering items which may be closely related in considering a given subject or phase of a subject. This difficulty has been overcome in the "Departmental Index of Plant Equipment," which will be found extremely valuable in locating related information. The field is divided into general, pottery, and heavy clay products and under appropriate subheads will be found the numbers of all items to be consulted.

The remainder of the volume is devoted to a catalog section giving informative data regarding equipment and materials manufactured by different firms supplying the industry.

Because of its unusual reference value, this book should be indispensable to everyone connected with or interested in the manufacture of clay products. ALAN G. WIKOFF.

Recent Chemical & Metallurgical Patents

American Patents

Issued Nov. 14, 1922

The following numbers have been selected from the latest available issue of the *Official Gazette* of the United States Patent Office because they appear to have pertinent interest for *Chem. & Met.* readers. They will be studied later by *Chem. & Met.'s* staff, and those which, in our judgment, are most worthy will be published in abstract. It is recognized that we cannot always anticipate our readers' interests, and accordingly this advance list is published for the benefit of those who may not care to await our judgment and synopsis.

1,435,211—Electric Furnace.
1,435,219—Coking Process.
1,435,361—Coke-Oven Decarbonization.
1,435,382—Sorting Materials.

1,435,505 — Recovery of Metals From Fumes.
1,435,506 — Recovery of Metals From Fumes.
1,435,524—Treatment of Salt Mixtures.
1,435,650—Preparation of Cellulose Solutions.
1,435,652—Cracking Hydrocarbons.
1,435,727—Method of Concentrating Brine.
1,435,742—Production of Refractory Alloys.

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Barium Chloride From Black Ash Waste—J. H. McMahon has assigned this patent to the Mathieson Alkali Works, Inc. The process consists essentially of producing soluble barium compounds from the residue left after the leaching of black ash with water. As the process stands now, barium sulphate (and other barium ores as barytes) is treated with coal and reduced at a high temperature, from which process barium sulphide or black ash results. This black ash is leached free from barium sulphide and the resulting residue contains a great deal of barium carbonate. The residue or exhausted black ash is well ground and reduced to a finely divided condition, then heated with a solution of ammonium chloride, from which a reversible reaction results in the partial production of barium chloride. This reaction would soon reach a definite end point due to the formation of ammonium carbonate along with the barium chloride, which compound would react to the original barium carbonate and ammonium chloride. To get around this difficulty, the solution is either agitated with air or boiled vigorously, which gets rid of the ammonium carbonate, and the process then goes to completion with the formation of barium chloride.

The mineral can either be treated according to the black ash process first, or it may be treated with ammonium chloride first and the remaining sulphate reduced with black ash. It is stated that the reaction with ammonium chloride will be 90 per cent completed after an interval of about 3 hours. The barium chloride thus formed is in solution and may be recovered by filtering, evaporating or crystallizing in the usual manner. (1,428,646. Sept. 12, 1922.)

The Manufacture of Acetic Anhydride—H. W. Matheson and G. E. Grattan have assigned to the Shawinigan Laboratories, Ltd., of Montreal, the following processes for making acetic anhydride. Glacial acetic acid is heated from 60 to 200 deg. C., according to the pressure under which the reaction takes place, and is violently agitated until the acetylene gas, which is blown into the liquid, is completely absorbed. Acetic anhydride is formed when these two materials react in the presence of a small quantity of finely divided mercury salt. Five hundred parts of pure acetic acid from 96 to 100 per cent are treated with 25 parts of mercury oxide and to this are added 12 to 13 parts of concentrated sulphuric acid, in order to precipitate mercuric sulphate. Acetylene gas is then passed into the reaction kettle under a pressure of 40 lb. per sq.in., above atmosphere pressure.

The temperature is permitted to rise to 130 deg. At the end of about 2 hours a mixture of acetic anhydride, together with ethylidene diacetate and a small amount of acetaldehyde, will be left behind. The reaction mixture must be agitated during the absorption. Mercury salts are filtered out and the product purified by distillation. (1,425,500. Aug. 8, 1922.)

Coke-Oven Construction—The horizontal transfer flue common to all coke ovens of the vertical flue regenerator type has long been considered a source of structural weakness. To overcome this drawback the type of construction shown in the accompanying figures has been developed. The principle is em-

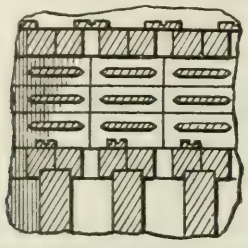

FIG. 1—LONGITUDINAL SECTION THROUGH HORIZONTAL FLUE

bodied in constructing the side walls of horizontal flue of what are called "notched brick." These brick are made with the ends of rectangular section, while the central portion is cut or notched until it has only a fraction of the cross-sectional area of the ends. In practice, brick of this type are laid so that the rectangular ends form the walls of the horizontal transfer flue, while the notched or cut-down parts form struts or braces between these two walls, thus serving to strengthen the structure.

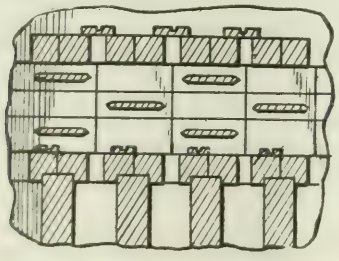

FIG. 2—ALTERNATE CONSTRUCTION

Fig. 1 shows a type of construction where every brick used is of this type. Fig. 2 shows an alternate type of construction which presents less resistance to gas flow but is not structurally as strong. (1,430,588. Arthur Roberts, assignor to the Chicago Trust Co. Oct. 3, 1922.)

Drying Apparatus Control—In the operation of the common type of drying apparatus which depends on the circulation of heated air for its drying effect, it is often desirable to maintain a predetermined humidity by controlling the amount of air which is re-circulated through the heating unit in relation to the amount of fresh air which is drawn in from the outside atmosphere. In this invention this is accomplished by locating in the air flues—on one side or the other of the fresh air inlet—a thermostatic diaphragm motor which operates a series of dampers regulating the openings in the various air passages. (1,431,145-1,431,146. J. E. Bolling, assignor to Drying Systems, Inc. Oct. 10, 1922.)

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Concentrating Coal—A process of separating coal particles of linear dimensions between 0.1 and 0.5 in. from shale or other gangue consists in submitting crude crushed or screened coal to treatment to coat the coal particles with a film of oil, and submitting the treated material to concentration by film flotation or subaëration flotation. The oiling may be effected by agitating a pulp of coal and water with an oil such as paraffine oil or fuel oil, or by immersing the coal in such an oil and then draining it. The coal may be first screened to separate out the particles of the size referred to, or the whole of the crushed coal may be treated together. In some cases, a frothing agent such as cresol may be added. (Br. Pat. 183,504. F. B. Jones and Minerals Separation, Ltd., London. Sept. 20, 1922.)

Artificial Silks—In the manufacture of artificial silk, films, etc., from viscose, an aqueous extract of certain plants is added either to the precipitating bath containing sulphuric acid and sulphates, or to the viscose itself. Salts of ammonia, triethylamine, pyridine, etc., may also be added to the bath. The materials used for making this extract may be the wood, stalks, leaves, needles, roots or fruits, particularly the needles, of conifers, and such roots or fruits as give mucilaginous extracts, such as mallow roots and linseed; and the extracting mediums may be water, solutions of acids or of substances having an acid reaction, or solutions having an alkaline reaction. The water extracts are obtained by boiling the material to be extracted with water under pressure, acidifying the extract, heating preferably to boiling point, filtering, and if necessary, concentrating preferably *in vacuo;* the salts necessary in the precipitating bath may be added to water during the extraction process, or they may be added to the extract. A similar procedure is adopted in the case of acid alkaline extractions; a suitable acid extracting medium is 5 per cent sulphuric acid, and as an alkaline extracting medium, solutions of sodium hydrate, soda or ammonia may be employed; "the dyes precipitated in the manufacture of viscose silk and soda-cellulose may also be used." The extracts may be rendered colorless by the addition of bleaching agents such as hydrosulphites, hydrogen peroxide or sodium peroxide or perborate, either during or preferably after the extraction process. From the needles of conifers is obtained "pine-needle extract," which extract contains terpene-like substances of particular value in the precipitation process; other extracts deficient in these substances may be improved by the addition of turpentine, turpentine oil, "pinon," dipentene, and the product obtained by reacting with acids on pinene, pinol, etc. (Br. Pat. 183,476; not yet accepted. Naamlooze Vennootschap Hollandsche Kunstzijde Industrie, Breda, Holland. Sept. 20, 1922.)

Synthetic Resins — Synthetic resins are formed by the direct action of acetylene on phenol or its homologs in the presence of acid and a mercury salt. Acetylene, preferably in excess, is passed into a mixture of the phenolic body with a little acid, such as sulphuric acid, or an acid salt to which mercurous or mercuric oxide or sulphate has been added; the temperature is preferably maintained at 50 to 120 deg. C.; increased pressure may be employed; a solvent for the phenol—for example, glacial acetic acid, an alcohol or acetone—may be present. Examples are given in which phenol and cresol are the starting materials, the resulting products being finally rendered infusible and insoluble by any method, such as treatment under heat and pressure with hexamethylenetetramine. (Br. Pat. 183,830; not yet accepted. Shawinigan Laboratories, Ltd., Montreal. Sept. 20, 1922.)

Wire Drawing — Dies for drawing tungsten wire, etc., are made from an alloy of tungsten and cobalt. The alloy may consist of 75 to 95 parts of tungsten to 25 to 5 parts of cobalt. The dies are made by producing the alloy by a thermo-aluminic process and then drilling and polishing. The alloy made may be sufficient to form a single die or a number of dies, in which case it is first sawed into pieces. In order to make the alloy, tungstic acid and cobalt oxide are first freed from moisture by heating at 400 deg. C. and are then mixed with fine-grained aluminum and fused in the ordinary way. (Br. Pat. 183,807; not yet accepted. Naamlooze Vennootschap Philips' Gloeilampenfabrieken, Eindhoven, Holland. Sept. 20, 1922.)

Soap—Soap, in a white and inodorous condition, is produced from soaps made from refined or unrefined oils, fats and fatty acids, or waste products of oil and fat manufacture, or from soapstocks obtained in deacidifying fats and oils, by spreading aqueous solutions of these materials over surfaces such as plates or rollers heated, for example, to 90 to 150 deg. C. By treating a thin film of soap at 100 deg. C., a dry product is obtained which on cooling takes the form of flakes. By using a lower temperature and a thicker layer of the solution, the amount of residual moisture can be regulated, and soap in pasty condition, suitable for making cakes or bars, is obtained. (Br. Pat. 183,837; not yet accepted. B. J. A. Nijdam, Wageningen, Holland. Sept. 20, 1922.)

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields
Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

More Tariff Rate Change Applications

Oxalic Acid Duty May Be Changed—Hearings to Begin in Two Weeks

Applications are continuing to pour in upon the tariff commission for changes in rates in the new tariff bill. Members of the commission declare that since the bill went into effect, only a few weeks ago, more than eighty applications have been filed for increases in rates for the protection of domestic manufacturers, reductions in rates for the benefit of importers, and for changes in classifications of commodities to lessen the burden of present rates on particular commodities.

Applications on Chemical Rates Numerous

The principal commodities represented by the applications filed to date, it was said, are chemicals and wool. In view of the comparatively large number of applications filed for changes in rates and the commodities agitating for these changes, officials do not consider the number of petitions filed as alarming.

Oxalic Acid Rate

The Advisory Board, supported by the report of the experts on chemicals, has filed data with the commissioners indicating that there is such a great difference in the comparative costs of oxalic acid in the United States and abroad and that a hearing well might be called to consider an increase in the rate on this chemical. A similar report has been filed on another chemical, which has not been identified.

It was learned upon good authority that the majority of the applications for changes in tariff rates, under the flexible provisions of the Fordney-McCumber act, represent chemicals and agricultural products.

Hearings in Two Weeks

The commission is having its commodity experts look carefully into the merits of the contentions before taking any definite action in the nature of open hearings, but officials are hopeful that the first hearings may be begun within the next two or three weeks, at which the commission may begin to take arguments on the accumulation of applications and decide the merits of the petitions.

Chairman Marvin of the commission is understood to be anxious to begin the hearings as soon as possible, and has urged experts of the commission to make every effort to this end. The difficulty met in obtaining the services of experts to investigate the applications as filed has slowed up the administration of the tariff measure and may yet delay the proposed hearings until the tariff machinery has been perfected.

Says Ford Will Get Muscle Shoals

That the disposal of Muscle Shoals to Henry Ford is but a matter of time was the announcement made by A. G. Patterson, president of the Public Service Commission, before the national convention of railway and utilities commissioners in Detroit last week.

When Muscle Shoals is completed, some of the vast amount of power developed there will be used for public utilities and, in that way, will come under the direct regulation of the commission.

"Never before have we been so certain that Congress will lease Muscle Shoals to Mr. Ford as we are today," said Mr. Patterson. "Muscle Shoals will go to Mr. Ford because no other party in the country has made, nor can make, an offer that compares with his. His nearest competitor is the Alabama Power Co., which is controlled by Wall Street capitalists. The South will never consent to have the destiny of its industries handed over to Wall Street control. The South trusts Mr. Ford because he does business on a conservative basis."

Physical Chemists Chosen as Editors of "Journal"

Announcement has been made of the selection of a board of editors for the *Journal of Physical Chemistry* to take over the burden of issuing that publication from Wilder D. Bancroft, of Cornell University, who has borne the entire responsibility of it for the past 18 years. The journal will be published in the future under the auspices of three societies, the Chemical Society of London, the Faraday Society and the American Chemical Society.

The following physical chemists have been named editors: By the Chemical Society of London, Professors T. M. Lowry, J. W. McBain and James C. Philip; by the Faraday Society, London, Prof. F. G. Donnan; by the American Chemical Society, Dr. A. L. Day, Prof. G. A. Hulett, Dr. Irving Langmuir and Prof. W. Lash Miller. Professor Miller is a Canadian member of the American society.

Trade Board Protests Alcohol Ruling

Urge Separation of Prohibition Enforcement and Industrial Alcohol Revenue Collection

Vigorous protest against the methods of the Treasury Department with regard to the legitimate commercial user of alcohol, who finds it almost impossible to keep abreast of the continuous stream of rulings emanating from Washington on the use of this chemical, was voiced at a meeting of the drug anl chemical section of the New York Board of Trade and Transportation in New York, last week.

In particular, the recent Treasury decision 3398 was condemned, since it is claimed that it is "an apparent attempt, without authority of law, to collect 25 per cent of the face value of a bond without resort to legal action, in addition to the penalties already provided for violations in the prohibition act itself."

Approval was given at the meeting to the protest of the committee on prohibition law enforcement and legislation of the board in this matter, which was stated in a letter to the Secretary of the Treasury, signed by Frank G. Starr, of Sharp & Doehme, chairman.

Urge Separate Enforcement

The committee also recommended a separation of the functions of the supervision of alcohol for industrial and other non-beverage purposes from the policing of violations of the prohibition law and urged the Commissioner of Internal Revenue to appoint a deputy commissioner to take over the industrial alcohol and chemical division of the prohibition unit.

University of Washington Offers Broad Course in Ceramics

The University of Washington, Seattle, Wash., announces the twenty-seventh annual winter mining session, to continue from Jan. 4 to March 21, 1923. No previous training is required for entrance. The expenses of the courses consist of laboratory deposits for material actually used and a university fee of $20.

The course in ceramics includes the study of clay testing, lime, plaster, cement, brick, stoneware, whiteware, refractories, glaze studies, clay technology and terra cotta manufacture. A postal card to the College of Mines, Seattle, will bring full details.

Agricultural Chemists Adopt Standard Methods

Value of Chemistry in Agriculture and Biology Stressed—Duplication of Scientific Work

During the deliberations of the Association of Agricultural Chemists in Washington last week, F. P. Veitch, retiring president of the association, made a plea for the elimination of waste in scientific work. In addition, he emphasized the importance which chemistry is playing in agriculture and in industry. In the course of these remarks Dr. Veitch, among other things, said:

"There are so many concrete things worth doing that the tendency to needless expansion and duplication is difficult to foresee or to check. Both are so wasteful of the people's funds, of time and effort that they should be guarded against at all times.

"Why has it been deemed necessary or even desirable for other organizations to repeat and duplicate much of the work done by this association? Why must three or perhaps more other organizations investigate the determination of the iodine numbers of oils? Why is it necessary for these organizations to do more than adopt these methods which are the outcome of many years of careful, thorough and impartial co-operative effort? What can be done to stop this waste of time and effort, and the doubt and conflict that result from the use of different methods?

Chemistry in Agriculture

"Years ago a distinguished member of this association remarked that no line of agricultural work progresses far before it is necessary to call in the chemist. This should be a more generally recognized fact. Take chemistry out of biology and nutrition and little but a name is left. Forget and abandon today's chemical knowledge in agriculture and industry, and civilization drops back two thousand years, because even two thousand years ago they were recognized as the rudiments of applied chemistry. In peace and in war it plays its major part."

Adopt Analytical Methods

With regard to boric acid in fertilizers, the association approved the following recommendation:

> That as boron compounds not soluble in water, but soluble in weak acids, appear to be as injurious to plants as the water-soluble compounds and since the Bartlett distillation method as now carried out determines the boron in such compounds, it is recommended that it be adopted as an official method in its present form to determine boron in mixed fertilizers and fertilizer materials.

Nitrogen Determination

With regard to nitrogen the following recommendations were approved:

> That the referee for 1923 be instructed to study the DeVarda method as applied to the nitrate of commerce.
>
> That the Moore method for nitrates be studied with collaborators next year.
>
> That the referee on nitrogen for 1923 be instructed to study the use of sodium thiosulphate as a substitute for sodium or potassium sulphide in precipitating mercury in the Kjeldahl method.

The association authorized the appointment of a referee to consider the determination of active acidity of hydrogen-ion concentration for agricultural chemical products.

Fertilizer Analysis Methods

With regard to potash, a recommendation to the effect that the investigation of the centrifugal method by Sherrill be discontinued was approved. The general referee on fertilizers was instructed to study the literature with regard to the use of alcohol, stronger than 80 per cent, for washing the potash precipitate with a view to ascertaining if collaborative investigation of the question is desirable.

A recommendation was approved to the effect that the determination of insoluble phosphoric acid in precipitated phosphates be carried out according to the present official method for the determination of insoluble phosphoric acid in fertilizers, with the exception that a 1-gram charge be employed.

Swedish Match Company Increases Capitalization

It is now definitely announced that the board of Svenska Taendsticks Aktiebolaget (Swedish Match Co.) has decided to propose that the present share capital be raised from 45,000,000 to 90,000,000 kroner. The new shares are to be issued at the rate of 120 per cent, thus bringing the total increase up to 54,000,000 kroner.

As the board of directors considers this amount too large for the Swedish market, an agreement has been entered into with a British company to place 40 per cent of the shares issued in England. It is expected that the company's shares will be quoted on the London Stock Exchange.

The new capital is to be used for the purpose of building match factories abroad, especially in India, this policy having proved advantageous. The company's exports of matches during the past few years have greatly increased and are now above the pre-war figure.

New York State Industrial Conference Considers Elimination of Waste in Industry

ELIMINATION of waste in industry was the watchword at the sixth annual New York State Industrial Conference which was held in Buffalo, N. Y., Nov. 21 to 24. Governor Miller, who had been expected to attend the opening session, wrote a letter that was read to the delegates.

"The limitation of waste in government is of equally great importance to the man of business and industry," the Governor wrote. "Industry and business, therefore, do well to meet and take counsel with government. The contracts made, the points of view acquired, cannot fail to be of service to the state, to business and to industry."

Welfare of Workers

Commissioner Henry D. Sayre reviewed the progress made in reducing the number of industrial accidents and said that with continued co-operation of industry itself further progress would be made, not only in reducing accidents, but in restoring injured to their full powers.

"The worker does not want to be coddled," said Mr. Sayre. "He does not want to be patronized. But he does want and is entitled to be protected from the effects of overfatigue and from the dull monotony of a constant repetitive process."

William D. Baldwin, of the Otis Elevator Co., spoke of better relations that exist between employers and employees now as compared with former times, for which, he said, much credit was due to workmen's compensation laws.

Wasteful Industrial Habits

Wasteful industrial habits are costing the nation billions of dollars anually, L. W. Wallace of New York City, executive secretary of the Federated American Engineering Societies, declared in addressing the convention. Lost production caused by ill health, physical defects and industrial accidents was a prolific source of waste, asserted Mr. Wallace, who said that the "42,000,000 men and women gainfully employed in the United States probably lose on an average more than 60 days yearly from illness or disability, including non-industrial accidents, or a total of more than 252,000,000 days."

The 12-hour day and the 7-day week were classed as wasteful industrial habits by Mr. Wallace, who cited the findings of the committee on work-periods in continuous industry of the Federated American Engineering Societies and the observations and experiences of John D. Rockefeller, Jr.

Management at Fault

Mr. Wallace held management responsible for conditions which slowed down production and produced increased cost, hardships and labor unrest. Cancellation of orders and the return of goods he characterized as vicious practices hindering stabilization. He commended Mr. Hoover's plan for an authoritative national information agency to aid managers of industry and commerce. High labor turnover he called another indictment of management. He advocated systematic and permanent study of the unemployment problem, ascribing to intermittent employment great waste. Labor difficulties in the clothing and building industries could be greatly reduced, he said, by the adoption of a more uniform production schedule.

Both management and labor, he charged, were guilty at times of criminal restriction of production, individually and collectively.

Paint Company Restrained on Charge of Misbranding of Goods

Charging methods of unfair competition in the misbranding of goods, the Federal Trade Commission has issued a formal complaint against John McQuade & Co., Inc., of Brooklyn, N. Y.

The concern is a manufacturer and seller of paints and similar products and is charged in the complaint with using on containers of certain of its products words and combinations of words which are not true descriptions of the contents of such containers. Among the words so used on labels, it is alleged, are the following: "French White Zinc," "Vieille Montagne Co., Paris," "Green Seal," "White Zinc" and "American White Lead."

Paint products so labeled, it is further charged, have definite meanings to the trade and others, in respective instances as follows: the words "Vieille Montagne" denote to the trade and to the purchasing public a zinc oxide commercially pure and one manufactured and sold by the Société des Mines et Fonderies de Zinc de la Vieille Montagne; that the term "Green Seal," when used to describe "White Zinc," signifies to the trade and to the purchasing public a high grade of white zinc; "White Lead," when used in labels placed upon commercial containers of pigments, signifies to the trade and to the purchasing public pigments composed wholly of commercially pure basic lead carbonate or basic lead sulphate. The commission's complaint alleges that the branding and labeling used by respondent is misleading and deceives the trade and the purchasing public because its goods so labeled do not conform with the above definitions.

Manufacturing Chemists' Association Protests Rate on Private Tank Cars

That the railroads should pay more for the use of privately owned tank cars is the contention set forth in a complaint filed with the American Railroad Association by the Manufacturing Chemists' Association. This action is taken largely in the interest of acid manufacturers. The American Petroleum Institute is taking similar steps with reference to privately owned oil tank cars.

Fertilizer Men Consider Protest on Freight Rates

Whether or not an attempt will be made to obtain an adjustment of the whole framework of fertilizer freight rates will be decided at a meeting of the traffic committee of the National Fertilizer Association which will be held in Cincinnati on Dec. 7. The fertilizer association contends that rates on fertilizers are higher than those charged on comparable commodities. It also is contended that lower rates will stimulate shipments and increase the profits of the carriers on this traffic.

Rarer Metals Symposium to Feature A.E.S. Meeting

Experts in Production and Applications of These Elements to Speak—Session on Electrode Potential

The growing importance of the so-called "rarer metals" is recognized by the American Electrochemical Society, which is planning an extended symposium on the subject at its forty-third annual meeting next spring. The convention will be held in New York, May 3, 4 and 5, 1923, headquarters being at the Hotel Commodore.

The symposium on "The Production and Application of the Rarer Metals" will occupy an entire day. Arrangements for this session are in charge of F. M. Becket of the Electrometallurgical Corporation, New York City. There will be papers on vanadium, tungsten, cobalt, molybdenum, zirconium, cerium, uranium, tantalum, calcium, magnesium and others.

Among the speakers will be: H. N. McCoy, president of the Carnotite Reduction Co. of Chicago; H. W. Gillett, of the Bureau of Mines, Ithaca, N. Y.; B. D. Saklatwalla, of the Vanadium Corporation; F. E. Carter, of the Baker Platinum Works, Newark, N. J.; H. S. Cooper (paper on zirconium metal); J. A. Holladay, of the Electrometallurgical Corporation (paper on analyses); M. A. Hunter, of the Rensselaer Polytechnic Institute, Troy, N. Y. (two papers; one on titanium); Mr. Clancy (paper on alloys as catalyzers); Mr. Cutter, of the Climax Molybdenum Co.; Russell Lowe, Bario Metal Corporation (paper on bario metal); Colin G. Fink, secretary of the society (paper on tungsten); C. E. Minor, Aravaipo Leasing Co., Klondyke, Graham County, Ariz.; W. R. Whitney, director of research laboratory, General Electric Co., Schenectady, N. Y.

Another session will be devoted to a discussion of "Electrode Potentials" headed by William G. Horsch, of the Chile Exploration Co., New York. The papers will cover studies on reversible electromotive force, overvoltage, ion activities and dissociations, electrotitration and p_H determinations.

Heavy Fire Loss at Plant of Duquesne Steel Co.

The plant of the Duquesne Steel Foundry Co. at Kendall, Pa., was threatened with destruction by a fire on Nov. 20, which destroyed one of the main shops of the plant. Shortly before midnight companies from five adjoining villages assisting the Kendall department apparently had the conflagration under control.

A preliminary estimate of the loss, made by an official of the company, was $350,000. The cause has not been ascertained, but the flames spread with great rapidity and threatened two oil tanks in the heart of the plant, which covers twenty acres. The company manufactures steel castings and locomotive cranes.

Photography to Feature Joint Meeting of Societies in New York

The monthly meeting of the Society of Chemical Industry, to be held at Rumford Hall in the Chemists' Club, 52 East 41st St., New York, has been postponed from Friday, Dec. 1, to Friday, Dec. 15. The evening will be devoted to papers dealing with some of the chemical or physical aspects of photographic science, with special reference to the uses of photography and motion pictures in the industries. A paper dealing with the last-named aspect—the application of photography and motion pictures to industry—by Dr. A. B. Hitchins, director of the research laboratory of the Ansco Co., Binghamton, N. Y., will open the proceedings, and this will be followed by an address on "Some Chemical Aspects of Photographic Science," by Dr. F. F. Renwick, director of the Redpath laboratory of E. I. du Pont de Nemours & Co., Parlin, N. J. The third paper will be by Dr. Herbert E. Ives, research engineer of the Western Electric Co., New York, who is to take for his subject "Color Measurement as Utilized in Color Photography." This paper will be illustrated by lantern slides.

The members of the Technical Photographic and Microscopical Society are invited to attend this meeting, which has been planned for their benefit as well as for the members of the American Section of the Society of Chemical Industry.

New Surgical Suture Invented in Wisconsin University

A skin suture for use in surgical operations that leaves no unsightly scars and combines all of the advantages of horsehair with none of its disadvantages has been recently invented by Prof. Louis Kahlenberg of the chemistry department of the University of Wisconsin and has come to be extensively used by surgeons in America, Europe and the Philippine Islands. This new suture, called "equisetene," is made by chemically treating silk so that tissue cells cannot penetrate the meshes of the silk. The treatment overcomes the disadvantages which surgeons had found in silk as a suture, and makes a smoother, more uniform material for use in surgical operations, it is said.

First Soda-Pulp Mill in Canada Planned by Smith Company

After a meeting of the directors of the Howard Smith Paper Mills in Montreal, Canada, it was announced that the company would proceed shortly to erect a plant for the manufacture of bleached soda pulp. So far Canada has imported what it needed.

The soda pulp will be used for mixing with sulphite pulp to go into the manufacture of certain grades of paper, the varieties produced by the company having grown to a marked extent in the past couple of years.

Domestic Tungsten Industry Slack

In Spite of Price Rise Due to Tariff, American Producers Cannot Operate Profitably

Due in part to natural economic pressure but largely to imposition of a tariff rate equivalent to $7.14 per unit, the price of tungsten has steadily risen in the United States from quotations of $1.85 to $2 per unit as late as last March to around $8 per unit. Even at the increased price, domestic mines remain idle, for the second year since 1899. Domestic production ceased after 1920, when the average price dropped to $7.86 per unit from the $18.02 average of 1919, which latter was the lowest average price over a course of years.

Despite the fact that reports to the Geological Survey indicate that there is 2 to 3 years' supply of tungsten in this country, there appears to be little prospect of a break in the market, as the supply is held in strong hands, willing to sell it only at favorable prices. Some steel makers are reported to have only a short supply remaining, indicating that demand will be stimulated before long.

Domestic Industry Cannot Compete

These factors favoring a price increase are offset, however, so far as domestic mining is concerned, by a study of figures compiled by Frank L. Hess, in charge of the rare minerals section of the Geological Survey, in a report covering 1921, which show that United States production of tungsten in 1918 was 5,061 short tons with an average price of $23.24 per unit and dwindled to 327 short tons in 1919, with an average price of $18.02; 216 short tons in 1920, with an average price of $7.86, and disappeared entirely after that year with further and drastic price declines. In 1915 the average price per unit was $29.30; in 1916, $33.98; in 1917, $18.40. Comparing the production table with the price table, it would appear that domestic mines do not find it profitable to produce tungsten when the price is below $20 per unit, and it is a long climb from the present range of $8 per unit to $20.

Most of the tungsten now on hand in this country came from China, where military operations have compelled continued working of the placer mines even at the very low price of $1.85 to $2 per unit, landed cost, which was paid here for some months. Although the price has risen to approximately $8 in the United States, Chinese tungsten still is being sold in England at around $3 per unit.

The new tariff rate is approximately four times the price at which tungsten was being bought here last spring. The old tariff act did not impose a duty on tungsten imports.

Vanadium Situation

The vanadium situation in the United States also is interesting. Produced here as a byproduct of radium, the output has ceased because of the radium market conditions. Imports, which have been principally from Peru, also have practically ceased. There is a supply in this country, however, equal to 2 to 3 years' normal demand for the product. The Ford Motor Co., which was the largest consumer of vanadium in its steel, no longer uses this alloy.

Corn Products Co. Called Monopoly

Charged With Price Fixing by Federal Trade Commission—President Denies Charge

Declaring that the Corn Products Refining Company, of New York, "makes the market," and through the medium of guarantees against price declines in table sirups has eliminated the competition of smaller companies, the Federal Trade Commission has issued a formal complaint against the company, which has a capitalization of $80,000,000.

In an extended statement, the Federal Trade Board explains that through the operation of the price guarantee system the Corn Products Refining Company has been able to force other competitors to lose their customers through lack of comparable resources.

Misinformed, Says Official

E. T. Bedford, president of the company, and Frank H. Hall, counsel for the company, have issued statements declaring that the charge has evidently been filed on misinformation of the facts existing in the table sirup and glucose trade.

"Guarantee against price declines is given by practically all large manufacturers who distribute their advertised package goods under their own label through the wholesale grocer," declared President Bedford. "It prevents speculation and effects uninterrupted distribution, resulting in economies in both manufacturing and cost of transportation, as well as the cost of selling, all of which are in the best interest of the ultimate consumer, who, by reason of the guaranteed price, gets a lower price and the immediate benefit of any decline in price."

Denies Price Control

"The Corn Products Refining Company controls neither the price of glucose nor of table sirups," said Mr. Hall. "The markets for both of these products are highly competitive. While it is true that the company has a larger capacity for producing glucose than any single one of its competitors, nevertheless the combined output of the competitors is considerably larger than that of the refining company. All of these competitors are substantial and aggressive.

Lively Competition

"It is quite true that the reports of sales of glucose and mixed sirups filed with the government show that if all our company's plants were closed down there would still be ample production of glucose and mixed sirups for all requirements."

Texas Potash Deposits Being Investigated

Geological Survey Making Analyses of Well Cuttings in Oil Fields

In conformity with the purpose of keeping the public fully informed regarding the progress of discoveries in the search for potash in western Texas, the director of the United States Geological Survey, Department of the Interior, has issued a statement of the results of the examination of samples of cuttings from two wells recently drilled there—the McDowell well No. 4, in Glasscock County, and the Texon Oil & Land Co.'s Santa Rita well, in Reagan County. The samples represent cuttings reaching depths of 2,550 and 4,426 ft. respectively in the two wells, but no samples representing a gap of 680 ft. between 1,010 and 1,605 ft. have been received from the McDowell well. There is also a gap of 2,205 ft. between the 1,683 and 3,888 ft. levels in the Santa Rita well from which no samples have been received.

The samples from the McDowell well ranged from 61.3 to 97.8 per cent soluble salts containing from 1.63 to 9.95 per cent K_2O. Those from the Santa Rita well showed from 47.4 to 93.7 per cent soluble salts containing from 1.86 to 10.78 per cent K_2O.

The samples thus analyzed, like those described in earlier announcements, were taken by standard tools from wells drilled primarily for oil. So many of the conditions attending the sampling are unknown that it is impossible to state whether the potash-bearing zones are a few feet or only a few inches thick. In the Santa Rita well, for example, the original sample taken from the bailer after the drill had cut the beds from 1,316 to 1,325 ft. showed 8.29 per cent of potash, equivalent to 10.78 per cent of the soluble salts, yet it cannot be safely inferred that there is a 9-ft. bed of potash salts of the stated richness at that horizon. Continuous sampling with core drills will be necessary before accurate data can be obtained.

Natural Indigo Production in India Falls Off

According to the first indigo forecast issued by the Department of Statistics of India, and based on reports received from six provinces, which contain practically the whole area under indigo in British India, the total area sown is estimated at 226,900 acres, which is 4 per cent below the estimate at the corresponding date of last year. As compared with the final estimate of last year (316,600 acres), the present estimate shows a decrease of 89,700 acres, or 28 per cent. The total yield of dye is at present estimated at 4,100,000 lb., as against 4,250,000 lb., the estimate at this time last year. As compared with the final estimate of last year, the present estimate shows a decrease of 33 per cent. Weather conditions at sowing time were not very favorable.

Cement Association Meets in Chicago

Officials of cement plants in all sections of the United States and Canada attended the sessions of the twentieth annual convention of the Portland Cement Association in Chicago last week. They brought optimistic reports as to improved conditions generally in the industry with bright prospects for the immediate future.

The convention opened Nov. 20, the various committees meeting in executive sessions to prepare reports which were submitted at the general sessions. L. T. Sunderland, president of the association, presided, and the program included the reading of papers on subjects pertaining to cement manufacture and mill practice. A. C. Tagge submitted a report of the special committee on accident prevention and insurance. C. H. Sonntag of the Cape Girardeau Portland Cement Co. read a paper on the waste heat installation in the plant of that company, and W. P. Gano, chief chemist, Pennsylvania Cement Co., read a paper explaining the different influences on the grinding of portland cement clinker.

A feature of the convention was the presentation by Secretary of Labor James J. Davis to the association of a concrete bust of Robert Whitman Lesley, the first president of the organization, which was modeled and cast by the boys of Mooseheart.

Wesson and Alexander at N. J. Chemical Society

Jerome Alexander and David Wesson were the speakers at the November meeting of the New Jersey Chemical Society in Newark, Nov. 13. The former chose as his topic, "The Importance of Impurities," and under this heading discussed a wide range of phenomena in industrial chemistry in which the presence of a small amount of "impurity" is essential for satisfactory results. It will be readily understood that the scope of such a subject is almost unlimited, and it was a fact that Mr. Alexander's remarks covered a miscellany of products and industries from electrodeposition to Welsbach mantles. The effect of varying quantities of cerium in the thorium impregnating solution used in incandescent gas mantles was described.

There followed two reels of motion pictures presented by Dr. Wesson, through the courtesy of the Kirkman Soap Co., showing the preparation of the raw materials entering into soap manufacture and the processes used in an up-to-date borax soap plant.

Dr. Wesson spoke on the subject of the color comparison of oils, describing the development of instruments used for this purpose from the first crude tintometer to the extremely accurate K. and E. spectrophotometer which measures the amount of light which passes through an oil for different wave lengths.

British Adhesives Research Committee Reports

Emphasizes Need for Systematic Investigation of Problems in Adhesive Manufacture

Early in 1918 it was estimated that within a year the shortage of glue would seriously limit the output of aircraft. In the latter part of 1917, however, the probability of a shortage had already been foreseen and the attention of the enginering war committee of the Royal Society was called, by a memorandum from one of its members, to the necessity for the scientific study of adhesives. This committee referred the matter to the Conjoint Board of Scientific Societies, which body called together an adhesives committee representative of the numerous aspects of the subject, both theoretical and practical.

Investigation Scope

Having in view the conserving of the existing supplies of raw materials for adhesives and cements, the committee set to work to devise improved and more economical methods of manufacture and to discover, if possible, new sources of supply. At the outset, the four following lines of inquiry were adopted:

1. An attempt to evolve physical and mechanical glue tests such as would differentiate between samples of tolerable merit. In this way it was hoped to obtain a closer knowledge of the characteristics of good adhesive cements and glues for wood.

2. To ascertain to what substance or substances and to what properties of such substances the adhesive strength of the gelatine base glues is due.

3. To discover whether and where wastage of raw material occurred in the course of the existing manufacturing processes and to suggest a remedy.

4. To examine, from the point of view of their adhesive power, the physical properties of substances obtainable from sources other than bone, hide or casein, and, if possible, from waste products of which supplies existed in England.

For several months the work of the committee proceeded along these lines and a number of useful results were obtained and are described in the first report. The experience already gained had shown that the need for a systematic investigation of the general problems of adhesives was very great and the results and experience already obtained gave hope of success.

Widespread Application

Adhesives are materials of very widespread application in industry; practically every branch of manufacture utilizes them in some form at some stage. Considerable progress has been made in the development of vegetable adhesives and in their industrial applications. Much work has also been done upon the chemistry of gelatine and gelatine glues, and in particular an attempt has been made to discover the nature of the changes occurring during the formation of gelatine from its precursors in animal tissues.

In the manufacture of glues and other adhesives there are very wide variations in the processes employed by different firms and in the character of their finished products. It would seem, indeed, that with a few exceptions the manufacturing processes employed in England are purely empirical, and without any real scientific basis. From this frequently follows an output of lower yield and grade than should be the case. It is hoped that the investigations of the committee will be of assistance in the evolution of a sound technology of glue manufacture. There exists a prejudice against adhesives, other than the common gums, derived from vegetable sources. It seems by no means improbable that valuable adhesives should be obtainable from such sources, and this expectation is strengthened by the results which have so far been gathered.

Experiments on Blast-Furnace Operation

Although the chemistry of iron blast-furnace reactions are fairly well understood, it has not been possible, due to the size of the commercial iron blast furnace and the loss involved when a furnace freezes, to operate a furnace experimentally except within those narrow limits which operating practice has proved not to be dangerous. Such being the case, the metallurgists of the Bureau of Mines have for some time past been carrying on experimental research work having for its ultimate object the construction of an experimental iron blast furnace of such dimensions as to be operated continuously and during the operation of which the conditions in the furnace would approximate those obtained in regular blast-furnace practice.

Based upon the data obtained from thirty-three different experiments, the bureau's metallurgists at its station at Minneapolis designed and constructed an experimental iron blast furnace. A 10-day test was recently made wherein no mechanical difficulties were encountered which materially hampered the operation of the furnace. The test also cleared up several metallurgical points concerning which considerable doubt had previously existed, such as the ability of a small experimental furnace to make "bosh gas" (35 per cent CO, 65 per cent N_2 in the combustion or tuyere zone); the size of the coke necessary; the number and size of tuyeres; amount of wind necessary; temperature of the blast, and temperature of the coke reaching the tuyere. It was likewise doubtful whether a small furnace would produce a gas sufficiently reducing in character to reduce oxides of iron and manganese; whether it would be possible to incorporate the proper amount of carbon in the metal produced; and whether the slag and metal could be removed from the crucible at the proper time.

Report of Canadian Chemical Industries

The gross value of chemicals and allied products manufactured in Canada in 1920 was approximately $122,000,000, according to a report published from the Dominion Bureau of Statistics at Ottawa.

The report states that the actual capital invested in the 456 plants operating in this group of industries in 1920 was $120.000,000. Pigments, paints and varnishes made in forty-eight plants were valued at $27,000,000 and with this output was first in the field. The report covers ten principal industries producing, respectively, coal tar and its products; acids, alkalis, salts and compressed gases; explosives, ammunition, fireworks and matches; fertilizers; medicinal and pharmaceutical preparations; paints, pigments and varnishes; soap, perfumery, cosmetics and toilet preparations; inks, dyes and colors; wood distillates and extracts; miscellaneous chemical industries.

Import Statistics

The imports of chemicals and allied products into Canada have gradually increased from $3,469,000 in 1895 to $24,000,000 in the 12 months ended March, 1922. The exports of Canadian products of the same class has risen from $760,000 in 1892 to $9,000,000 in the 12 months ended March of the present year. During the war the great production of explosives in Canada and the shipment of this commodity to the war zone raised the Canadian exports of chemical products to a grand total of $57,000,000 in the 12 months ended March, 1919. The present export figures show that much of the advantage gained in the war-time development has been retained, and the fact that the summary statistics for the calendar year 1921 showed that 444 plants were in operation as compared with 456 in the preceding year is further evidence that the chemical industries of Canada are more than holding their own.

Copies of the report on chemicals and allied products for 1919 and 1920 may be had on application to the Dominion Bureau of Statistics, Ottawa.

Illinois Industries Urged to Save Coal

Industrials in Illinois are urged to conserve and store coal by the Illinois Manufacturers' Association. In an effort to aid fuel economy the association has sent out hints based on a circular issued by the engineering experiment station of the University of Illinois. These hints deal particularly with fuel economy in the operation of hand-fired power plants and point out that practically the only fuel available for power plant use in Illinois under present conditions is bituminous coal from the central fields of Illinois, Indiana and western Kentucky.

"The care with which the coal is 'prepared' and separated into different sizes is an important factor affecting its value in the power plant," the circular states. "The B.t.u. value and the percentage of ash furnish a general guide to the relative values of Illinois coals. Generally the coals having the lowest ash content have the highest B.t.u. value."

The circular recommends the storage of bituminous coal, provided the prescribed precautions are observed. It also enumerates the conditions necessary for complete and smokeless combustion of bituminous coals.

Novel Government Guide to Latin America

The new revised edition of the "Commercial Travelers' Guide to Latin America" has just been released by the Department of Commerce. It is an encyclopedia of the countries south of the United States. It is the only complete and up-to-date "Baedeker" for the traveler. Everything that a foreign representative should know is included within its 698 pages; salesmen's equipment, steamship routes and railroads, connections and rates, schedules of sailings, postal and cable services and rates, hotel accommodations in the various cities, restrictions on travelers, duties on samples and advertising matter.

Everything a commercial traveler ought to know about the twenty republics and the many colonies to the south of us to make a trip profitable as well as enjoyable is encompassed within these 734 pages; steamship lines and railroads, time tables and connections, road routes, hotels and rates, taxes on travelers and restrictions, duties on samples and advertising matter; nothing essential is omitted. The traveler is told about the banks, postal service and postal rates, weights and measures, and all things that may obviate those vexatious delays which are especially troublesome to the uninformed and inexperienced traveler in Latin America.

Every city and market of importance in the Latin Americas is listed with information as to its characteristics, trade regulations, license fees, routes by which to reach it, etc., and the traveler is given abundant sound advice to be followed in canvassing each section.

This rather unusual publication is a decided novelty—quite a departure from the usual routine of official bulletins. Its attractive binding, with stout flexible covers, thin paper and convenient paragraph headings, is an unusual feature. One of the most important items in the guide is the series of more than forty maps which were specially drawn for this publication and are based upon the most recent authentic data regarding railway lines, commercial centers, etc. The guide may be obtained by applying to the Superintendent of Documents, Government Printing Office, Washington, D. C., or to any of the district or co-operative offices of the Bureau of Foreign and Domestic Commerce, price $1.25 prepaid.

Automobile Interests Finance Oil Refinery in Canada

Ground has been broken in Montreal, Canada, for one of the largest and most up-to-date oil refineries on the continent. It is being financed by prominent Canadians, associated with a group of Detroit automobile manufacturers, headed by Benjamin Briscoe, who since selling his Briscoe Motor Corporation interests in 1917 is now one of the principal stockholders in the Gray and the Durant motor companies. The new corporation, the Red Star Refineries, Ltd., with a paid-up capital of $6,000,000, controls the Ramage process for the refining of petroleum. It is claimed for this process that a much superior quality of gasoline is obtained from the crude oil.

The Red Star Refinery now under construction is on the St. Lawrence River, on deep water, where the company's tankers will bring the crude oil from Mexico and the Gulf ports. When finished, this refinery will have a capacity of 10,000 bbl. of "Super-Gas" per day.

Personal

C. F. Geiger, ceramic engineer of the Carborundum Co., Keasbey, N. J., was the principal speaker at the regular monthly meeting of the Rutgers Ceramic Club, Rutgers College, New Brunswick, N. J., Nov. 16. He gave an illustrated address on "Carborundum Refractories."

Ivar J. Moltkehansen, after 20 years practice in the United States, Norway and Belgium, has opened offices as a consulting electrochemical engineer at 44 Avenue Beau Séjour and 13 Rue Bréderode, Brussels, Belgium.

Arthur Rosenhain of England will deliver the second annual lecture before the Institute of Metals Division of the American Institute of Mining and Metallurgical Engineers on Feb. 19, 1923. His subject will be "Solid Solutions."

W. R. Shimer, metallurgist of the Bethlehem Steel Co., Bethlehem, Pa., addressed the Washington Chapter of the American Society for Steel Treating, Nov. 24, 1922, on "The Manufacture of Steel."

Victor Yngve has resigned his position with the Hydrol Co. of Niagara Falls, N. Y., to accept a research fellowship in cryogenic engineering at Harvard University, Cambridge, Mass.

Obituary

Spencer Kellogg, head of Spencer Kellogg & Sons, Inc., Buffalo, N. Y., producers of linseed, core and other oils, died at his residence, Nov. 14, at the age of 71 years, as a result of an attack of acute indigestion. He entered the linseed oil business in 1872.

Market Conditions

In Chemical, Metallurgical and Allied Industries

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities
Prevailing Prices and Market Letters From Principal Industrial Centers

The Significance of the Stock Dividend

Many Companies in the Chemical and Allied Industries Are Capitalizing Their Accumulated Surpluses by Participating in This Record Distribution

DURING the past few weeks has occurred the largest distribution of stock dividends in the history of finance. The total issue announced by forty stock companies during the last 30 days amounts to $1,119,000,000, or slightly more this country's total national debt in 1914. The fact that the chemical and related industries have figured prominently in this movement may be regarded as convincing evidence of the widespread improvement occurring in these industries and also as an encouraging forecast of the earnings which these companies are likely to show in their annual reports for 1922.

A number of reasons have been assigned for the distribution of these dividends at this time, but it is believed that the principal motive may be found in the 1921 revenue law. That law differs from its predecessors in that it prescribes a flat rate of 12½ per cent on corporation profits. On the other hand the tax on individual incomes remains as in 1920 and 1921 on a sliding scale—the surtax steadily increasing from 1 to 65 per cent depending upon the size of the income. Another novel feature of the revenue law, known as the capital investment tax, makes it possible for large holders of securities, which have been owned for a period of 2 years or more, to liquidate their holdings and pay a straight tax of 12½ per cent on the profit from this sale, instead of paying the regular surtaxes.

Accordingly for some time there has been a tendency to forestall heavy outlays for taxation by allowing profits to remain in the business. This has brought about large accumulations of surplus accounts by many companies. In order to put this money to a more useful purpose, and guided perhaps by the rumors that Congress might attempt to impose a heavy tax on all accumulated surpluses, many concerns have found it advisable to capitalize their surplus accounts in the form of stock dividends.

An example may serve to show more clearly how the law operates. Suppose John Smith has a personal income of $75,000, on which he is required to pay the government a surtax at the rate of 35 per cent. Suppose, too, he owns a controlling interest in a corporation whose earnings would permit the payment to him of a cash dividend of $25,000. If he accepts that as cash, his income is increased to $100,000, and he must pay a surtax at the rate of 47 per cent. Naturally he does not want to accept such a dividend, for by leaving his profits in the business, only 12½ per cent need be paid in taxes.

Standard Oil and du Pont Dividends

The Standard Oil companies in New Jersey, New York, California, Kansas and Kentucky were among the first to announce stock dividends. That of the New Jersey company, which amounted to 400 per cent of its capital stock and corresponded to a distribution at par value of $395,517,000, was given wide publicity by members of Congress, who attempted to interpret the action as a tax evasion. Many other oil companies followed the example of the Standard companies, as may be observed from the accompanying compilation.

On Dec. 4 the directors of E. I. du Pont de Nemours & Co. will, with the approval of their stockholders, declare a 50 per cent stock dividend. The authorized capital stock was increased on Nov. 10 from $80,000,000 to $100,000,000 by the addition of 200,000 shares of $100 par value. The dividend rate for the new issue will be announced by the directors at their February meeting but it is generally believed that it will be the same as that on the old stock, namely $8 per share.

Since the du Pont stock was listed on the New York Stock Exchange in May, 1922, it has increased in value from $115 per share to $169.25 on Nov. 10. By Nov. 21 it had fallen off slightly to $154. In its annual report for last year the du Pont company reported that it had 10,579 stockholders, of whom 3,342, or 35 per cent, were employees.

Among the important industrials in the chemical, metallurgical and allied fields that have recently declared stock dividends are the following:

Company	Per Cent	Par Value Distributed (000 Omitted)
Standard Oil Co. of N. J.	400	$395,517
Standard Oil Co. of N. Y.	200	150,000
Standard Oil Co. of Cal.	100	100,971
Standard Oil Co. of Kans.	300	6,000
Standard Oil Co. of Ky.	33⅓	2,000
E. I. du Pont de Nemours Co *	50	20,000
Magnolia Petroleum Co.	50	58,675
Solar Refining Co.	100	2,000
Ohio Oil Co.	300	45,000
National Biscuit Co.	75	22,927
Vacuum Oil Co.	300	45,000
National Fuel Gas Co.	100	18,500
National Sugar Co.	50	5,000
U. S. Gypsum Co.	10	99†
Great Northern Paper Co.	200	16,800
Ingersoll-Rand Co.	100	15,000
Pan American Petroleum Co.	25	17,500
Scovill Mfg. Co.	200	10,000
Timken-Detroit Axle Co.	150	4,467
Union Natural Gas Co.	75	7,500
American Steel Foundry Co.	18	3,600
Hercules Powder Co.	100	10,000
American Mach. & Fdry. Co.	200	4,000
Gulf Oil Corp. †	200	72,290
Pure Oil Co.	75	1,568

*Pending stockholders' approval, Dec. 4, 1922.

†Not announced as a stock dividend but distributed to stockholders under a capital readjustment plan.

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	162.45
Last week	162.83
November, 1921	146.82
November, 1920	240
April, 1918 (high)	286
April, 1921 (low)	140

The only items to show a change during the past week were caustic soda and linseed oil—both of which fell off slightly during the interval. The only effect on the index, however, was to lower it 0.38 of a point.

Taxes Claim One-Sixth of the National Income

In the fiscal year 1913-1914, taxes paid to national, state and local governments in the United States represented 6.4 per cent of the national income. By 1919-1920 the ratio had grown to 13 per cent and by 1920-1921 to 14.3 per cent. In the calendar year 1921, one-sixth of the current national income was diverted into tax channels for the support of governmental bodies in the United States.

This is one of the conclusions drawn by the National Industrial Conference Board after a comprehensive study of public expenditures and taxation in this country and abroad. "Under present conditions," the Conference Board's report concludes, "the tax bill in the United States is fast making inroads on the surplus necessary for economic progress and threatens materially to hamper our growth, especially in view of the uninterrupted rise in local government taxes. It is a question of growing importance whether a reduction in and wider diffusion of national tax burden may not be desirable, not only for the protection of the national surplus but in order to awaken a more general interest in the activities of the government."

Coal Problem Solved for This Winter (Except the Price)

The fuel situation has become stabilized to such an extent that the Chamber of Commerce of the United States recently notified its members that surveys and reports are no longer necessary, as the program adopted in September to equalize coal distribution, through co-operation among users in the period immediately following the strike, has been successful.

The resumption of large-scale industries such as steel plants and the relatively high operation of other plants show that industrial coal is adequately distributed and there is no apprehension about future supplies. The domestic user is clearly assured of domestic supplies, although individual preference as to kind and description may not always be met and may require some substitution of other coal.

Coal Production Up

The United States Geological Survey reports that bituminous coal production for the week Nov. 13-18 was 11,213,000 tons, as against 10,147,000 tons in the week preceding. Early returns for the week Nov. 20-25 indicate that 11,000,000 tons will be raised. Both bituminous coal and anthracite output in the week ended Nov. 18 were at high rates, and the total coal raised, 13,404,000 net tons, was the highest weekly outturn since the strike and was exceeded this year only in the week ended March 25, when the total outturn was 13,543,000 net tons.

Beehive Coke Output

Production of beehive coke continued to improve during the week ended Nov. 18. The estimated total output, based on the number of cars loaded, was 261,000 net tons, against 246,000 tons in the week preceding. Increased activity in the Pennsylvania-Ohio district was the principal factor in the improvement. According to the Contrict was the principal factor in the Connellsville region increased from 176,880 to 182,380 tons, the highest record attained since the beginning of the strike.

The cumulative output during 1922 to date stands at 6,310,000 net tons. In the corresponding period of the 4 years preceding it was as follows: 1921, 4,826,000 tons; 1920, 18,826,000; 1919, 17,376,000, and 1918, 27,627,000.

National Lead Pays Eight Per Cent

By declaring a quarterly dividend of 2 per cent on Nov. 23, the National Lead Co. placed its common stock on an 8 per cent premium basis as compared with the previous rate of 6 per cent. The dividend is payable Dec. 30 to stock of record on Dec. 15. The statement was made by President Cornish that the $4,000,000 in unissued common stock held by the company will remain as a reserve to be used for the extension of the business of the National Lead Co. and its subsidiaries.

The New York Market

New York, Nov. 20, 1922.

The chemical market continued along moderately active lines during the past week. Inquiries were quite abundant from various consuming industries for contracts over next year on some of the more important commodities, but as yet the producers have not shown any general inclination to accept this business. Resale stocks have been noticeably diminished and producers reported a sold-up condition for the remainder of the year on some products. Powdered white arsenic continued to be the feature of the week's trading and prices have reached new high levels. Actual transactions to the consuming industries have not been plentiful, but speculation among second hands on limited spot stocks has been the chief cause of the steady advance. Producers of acetate of lime announced another advance of ½c. per lb. Increased production costs and a stronger demand have been responsible for the new price.

The alkali market has also shown an appreciable improvement, especially for domestic consumption. Large producers seem well satisfied with the present volume of business and state that some new inquiries have recently been received from Japan and Italy for large tonnages. Red prussiate of potash is exceedingly strong on spot and sellers are asking top prices on limited stocks. Muriate of potash prices were advanced by leading importers. Formaldehyde retained its former strength without any quotable change.

General and Special Chemicals

Acetate of Lime—Producers advanced the market to $3.50 per 100 lb., for carload quantities, in bags. Higher production costs and better demand are responsible for the new price.

Arsenic—Quotations have again been advanced to 13½c. per lb. and the market during the latter part of the week was firmly established at this level. The insecticide industry has shown considerable activity.

Bichromate of Soda—Sales have been recorded at 7½@7¾c. per lb. for spot material and the market appeared firm at this level. Export business was fairly active.

Barium Chloride—The lowest figure heard for spot material was around $95 per ton, with the range at $95@$100, according to quantity. Shipments from abroad were held at $92 per ton.

Caustic Soda—The export market continued along moderate lines and prices were fractionally lower. The bulk of trading, however, is being done among domestic consumers. Contracts for the balance of the year are in very strong demand. Producers have not announced any prices for 1923. Spot quotations f.a.s. range around $3.50@$3.60 per 100 lb., with ex-warehouse goods held at $3.75@$4 per 100 lb.

Muriate of Potash—Quotations are somewhat higher on imported material at $35.75 per ton, basis 80 per cent.

Fluoride of Soda—Several sales of imported material were recorded at 9½c. per lb. Buyers are only purchasing for immediate requirements and the market showed some weak spots.

Oxalic Acid—Producers continue to quote 14c. per lb., f.o.b. works. Odd lots were heard around 14@15c. on the spot market. Foreign shipments were quoted at 13½c. per lb., duty paid.

Sal Ammoniac—White granular imported goods were much firmer during the week and prices ranged around 6¾c. per lb. The gray material continued firm at 8½c. per lb.

Soda Ash—Domestic demand has been quite strong and producers report heavy shipments at $1.75@$1.80 per 100 lb. for the 58 per cent, light, single bags. The export demand is moderate.

Vegetable Oils

Linseed Oil—Immediate shipment oil was quoted down to 85c. per gal., due to the unfavorable reports from the Argentine market. Late December delivery was reported at 82c. per gal., carload lots, in barrels. January-April oil was offered at 76@78c. per gal.

Coconut Oil—A good inquiry was reported for the Ceylon type oil, but the high figures restricted trading to a considerable extent. Prompt shipments held around 8c. per lb.

Corn Oil—The market for crude oil ruled steady at 8½c. per lb, f.o.b. Chicago, sellers' tanks. Spot oil in barrels was available in a small way at 10@10¼c. per lb.

Palm Oil—Foreign despatches reported a steady market, although spot prices remained quotably unchanged. Niger oil on spot was very scarce at 7¾c. per lb.

Peanut Oil—Domestic crude oil was purely nominal in the absence of any new crop offerings. The high cost of peanuts makes it almost impossible to produce any oil. Refined edible oil on spot was scarce at 13½@14c. per lb. in barrels.

Crude Rubber

General conditions in this market were somewhat easier during the past week and prices showed fractional declines for deliveries up to March, 1923. Trading was merely routine and buyers showed some disposition to hesitate at the present high levels. Smoked ribbed sheets and first latex were quoted at 24c. per lb. for December. January-March held at 24½c. and April-June at 25⅛c. per lb.

The Chicago Market

Chicago, Nov. 23, 1922.

But little change could be noticed in the condition of the industrial chemical market in this district. The tone of the market was firm, with both dealers and manufacturers reporting a very satisfactory volume of business. Its main feature has been the rapidly advancing prices on wood chemicals, which have risen nearly 100 per cent during the past 6 weeks. Imported chemicals are now at about the same price as domestic and in some instances higher.

Caustic soda maintained its firm posi-

tion and dealers report a good volume moving to the consuming trade. Prices were unchanged, with the solid 76 per cent quoted in ton lots at $3.50 100 lb. and the ground or flake in similar lots at $4.25. *Caustic potash* lacked quotable change and was reported as moving in a fair way at 7¼@7½c. per lb. *Soda ash* continued to be in good demand and supplies were available at $2.25 per 100 lb.

Potash alum was quiet, with mostly foreign material offered. The U.S.P. lump was quoted in small or moderate lots at 4½c. per lb. and the same grade in powdered form at 6½c. *Barium compounds* were unchanged in price and were rather quiet. The chloride was available in ton lots at $110 per ton and the carbonate at $90. *Barium hydrate* crystals were in limited request and spot goods could have been had at 6@6½c. per lb. *Ammonium chloride* moved in a routine way and the white granular was quoted at 7⅞@8c. per lb. *Ammonium carbonate* was quiet, with spot stocks of the lump held for 11c. per lb. *Copper sulphate* was unchanged in price and moved in a fair way at 6c. per lb. for small or moderate lots. *Carbon bisulphide* was scarce on spot and was held at 7½c. per lb. for single drums. *Carbon tetrachloride* was reported to be in good demand and spot stocks were quoted at 9@9½c. per lb. Following the advance on methanol *formaldehyde* was advanced to 15½c. per lb. in barrels. The advance was firmly maintained and dealers reported a very good volume of business at the new level. *Glycerine* was in a somewhat weaker position but the price of 18½c. per lb. for the c.p. material was maintained. *Lead acetate* was in fair demand and material on spot was quoted at 12½@13c. per lb. for the white granular.

Bichromates were firm and unchanged in price, with fair supplies reported to be moving to the consuming trade. *Potassium bichromate* was quoted at 12@13c. per lb., and the sodium salt at 9@9½c. *Potassium bicarbonate* was dull at 9½@10c. per lb. for the U.S.P. crystals. *Cyanide of potash* was very scarce and single-case lots were available from one source at 55c. per lb. *Red prussiate of potash* continued very scarce with only very small lots available at 95c.@$1 per lb. *Potassium permanganate* was rather quiet, with supplies of the U.S.P. small crystals quoted at 18½@19c. per lb. *Chlorate of potash* was very firm and small lots of powdered were quoted at 9c. per lb.

Linseed Oil and Turpentine

Turpentine is now so high priced that very little is moving and some of the consumers are taking up substitutes. Single-drum lots were offered for immediate acceptance at the opening of today's market at $1.69 per gal.

Linseed oil was firm in price, but the movement was reported as light. Single drums of the boiled was offered today at 95c. per gal. with similar quantities of the raw at 93c.

The Iron and Steel Market

PITTSBURGH, Nov. 24, 1922.

Steel mill operations seem to have had a slight further increase in the past week or two. Steel ingot production was at about 40,000,000 gross tons a year in October and may be estimated at a slightly higher rate this month. Cars are still in poor supply and from time to time there are various embargoes, but on the whole the current output is being shipped, together with some of the steel previously accumulated.

In wire products and tubular goods customers are exerting pressure upon the mills for heavier deliveries. In other lines there is no such pressure, but deliveries are evidently accepted freely, at as high rates as the mills can compass.

Finished Steel Markets Stagnant

As to actual sales and purchases, the finished steel markets on the whole are very quiet, practically stagnant, with certain important exceptions. Railroads continue to buy freely, orders reaching mills both direct from railroads and from car and locomotive shops, which are selling their product freely and have large inquiries before them. The automobile factories have formulated programs of production to April 1, and are in the market for the requisite steel. Although they are seeking as low prices as possible, they do not conceal their expectation of heavy operation. December is to be a light month in automobile production with the three succeeding months showing increases, the program involving heavier production in March than in any month of this year. The agricultural implement factories, while not operating particularly well, are doing better than formerly, and are buying some steel. The remarkable boom in garage and dwelling house construction causes pressure for delivery of nails and the smaller sizes of merchant pipe, and there is no little current buying of these.

Prices Barely Steady

In general, however, the finished steel market is quiet, and prices, far from advancing as they were doing for so many months, are barely steady. In view of certain long-range considerations, the ready acceptance of the present heavy deliveries is somewhat noteworthy. There is the general fact that steel prices advanced, on an average, rather sharply in connection with the coal strike, and the coal strike ended some time ago. The steel industry is left with higher costs than last March, but with the price level considerably higher still, and in the light of precedent the average buyer may be expected to seek lower prices before buying freely again. Another consideration is that production of steel since Oct. 1 has been at a rate more than 15 per cent greater than in the 6 months April 1 to Oct. 1. On account of the drastic liquidation in 1921, consumption April 1 to Oct. 1 could not have exceeded production, while now production is considerably greater and it is not the time of year for consumption to increase. This observation, noted in last week's report, applies with still greater force now and will apply probably until steel production begins to taper off, of which there is no visible premonition at present.

Steel Prices

Yesterday the American Sheet & Tin Plate Co. made its long-awaited announcement of sheet and tin plate prices for new periods. Contrary to expectations entertained very generally a month ago and still maintained in a few quarters, no advances are made, all prices being reaffirmed for the new periods. Tin plate is $4.75 per base box, 100 lb., for first quarter with jobbers and first half with manufacturing consumers, while sheets to all classes of trade for first quarter are 2.50c. for blue annealed, 3.35c. for black, 4.35c. for galvanized and 4.70c. for automobile. Independent tin plate makers had not been obtaining higher prices, although they insisted they ought to have higher prices. For a couple of months, all independents were obtaining higher prices for sheets, but lately there has been a recession to the Steel Corporation level, with the exception of automobile sheets, for which independents have still been trying to obtain 5c.

Bars, shapes and plates remain quotable at 2c., but the market is barely steady at that level, and no particular attempt is made to conceal the fact that on decidedly attractive orders slightly lower prices would readily be quoted by several sellers. Early deliveries are easily obtained. Delivery premiums on these lines disappeared recently.

Pipe remains quotable at 66 per cent basing discount, wire at 2.45c. and nails at $2.70. Hoops and bands are easier, desirable orders going at 2.75c., against 2.90c. formerly.

Coke and Pig Iron

The lack of coherence in market developments, or accidents, is illustrated by the fact that coal is down 50c. in the week, while coke, which is made from coal, is up 50c. and pig iron, which is made with coke, is down. Pittsburgh district steam coal is $2.75@$3, with byproduct at $3.50@$3.60 and high-grade gas coal at $3.60@$3.75. Connellsville furnace coke is $7.25@$7.50 for spot or prompt lots, and some of the best grades could scarcely be bought on contract to the end of the year at under $8.

Valley bessemer is quoted at $30 furnace, and it is not certain there would be any takers at that figure. Valley basic is offered at $27.50, without any inquiry. Single carloads of valley foundry have been going at $27.50. These prices are below those quoted a week ago by $2 on bessemer, 50c. on basic and $1 on foundry. The mere decline in prices is not remarkable, but the decline when there is so little inquiry to provoke active competition is distinctly notable.

General Chemicals

Current Wholesale Prices in New York Market

		Carlots F.o.b. N. Y.	Less Carlots F.o.b. N. Y.
Acetic anhydride	lb.		$0.39 – $0.45
Acetone	lb.	$0.19 – $0.20	.20 – .22
Acid, acetic, 28 per cent	100 lb.	2.92 – 3.00	3.05 – 3.20
Acetic, 56 per cent	100 lb.	5.85 – 5.90	5.95 – 6.25
Acetic, glacial, 99½ per cent, carboys, 100 lb.		11.16 – 11.20	11.25 – 11.50
Boric, crystals	lb.	.11 – .11½	.11½ – .12

Calcium carbide	lb.	.04½ – .04¾	.05 – .05½
Calcium chloride, fused, lump	ton	22.00 – 23.00	23.50 – 27.00
Calcium chloride, granulated	lb.	.01½ – .01¾	.02 – .02½
Calcium peroxide	lb.		1.40 – 1.50
Calcium phosphate, tribasic	lb.		.15 – .16
Camphor	lb.		.90 – .92
Carbon bisulphide	lb.	.07 – .07½	.07½ – .07¾
Carbon tetrachloride, drums	lb.	.10 – .10¼	.10½ – .12
Carbonyl chloride, (phosgene)	lb.		.60 – .75
Caustic potash (see potassium hydroxide)			
Caustic soda (see sodium hydroxide)			
Chalk, precip.—domestic, light	lb.	.04½ – .04½	
Chalk, precip.—domestic, heavy	lb.	.03½ – .03¾	
Chalk, precip.—imported, light	lb.	.04½ – .05	
Chlorine, gas, liquid-cylinders (100 lb.)	lb.	.05½ – .06	.06½ – .06½
Chloroform	lb.		.35 – .38
Cobalt oxide	lb.		2.10 – 2.40
Copperas	ton	27.00 – 28.00	29.00 – 30.00
Copper carbonate, green precipitate	lb.	.21 – .21½	.22 – .22½
Copper cyanide	lb.		.50 – .55
Copper sulphate, crystals	100 lb.	5.75 – 6.00	6.10 – 6.50
Cream of tartar	lb.		.25½ – .26
Epsom salt (see magnesium sulphate)			
Ether, U. S. P. 100 drums	lb.		.14 – .15
Ethyl acetate com. 85%	gal.		.72 – .75
Ethyl acetate, pure (acetic ether, 98% to 100%)	gal.		.90 – .95
Formaldehyde, 40 per cent	lb.	.14 – .14½	.14 – .15
Fullers earth, f.o.b. mines	net ton	16.00 – 17.00	
Fullers earth—imported powdered	net ton	30.00 – 32.00	
Fuel oil, bbl	gal.		3.00 – 3.50
Fuel oil, crude	gal.		2.00 – 2.25
Glauber's salt (see sodium sulphate)			
Glycerine, c.p. drums extra	lb.		.18 – .18½
Iodine, resublimed	lb.		4.40 – 4.50
Iron oxide, red	lb.		.12 – .18
Lead acetate, white crystals	lb.		.12 – .12½
Lead acetate, powd.	lb.	.13 – .13½	.13½ – .14½
Lead nitrate	lb.		.15 – .20
Litharge	lb.	.07½ – .08	.08½ – .09
Magnesium carbonate, technical	lb.	.06 – .06½	.06½ – .07½
Magnesium sulphate, U.S.P.	100 lb.	2.50 – 2.65	2.70 – 3.50
Magnesium sulphate, technical	100 lb.		1.00 – 1.80
Methanol, 97%	gal.		1.00 – 1.07
Methanol, 97%	gal.		1.03 – 1.10
Nickel salt, double	lb.		$0.11 – $0.11½
Nickel salt, single	lb.		.12 – .12½
Phogene (see carbonyl chloride)			
Phosphorus, red	lb.		.40 – .45
Phosphorus, yellow	lb.		.30 – .35½
Potassium bichromate	lb.	$0.09½ – .10	.10½ – .10½
Potassium bromide, granular	lb.		.17 – .23
Potassium carbonate, U. S. P.	lb.	.12 – .12½	.13 – .16
Potassium carbonate, 80–85%	lb.	.06 – .06½	.06½ – .06¾
Potassium chlorate, powdered and crystals	lb.	.07¾ – .08	.08½ – .09
Potassium cyanide	lb.		.55 – .57
Potassium hydroxide (caustic potash)	100 lb.	6.50 – 6.60	6.65 – 7.00
Potassium iodide	lb.		3.45 – 3.55
Potassium nitrate	lb.	.06½ – .06¾	.07 – .08
Potassium permanganate	lb.	.16 – .16½	.16¾ – .17
Potassium prussiate, red	lb.		.90 – .95
Potassium prussiate, yellow	lb.	.39 – .39¼	.39½ – .40
Rochelle salts (see sodium potas. tartrate)			
Salammoniac, white, granular	lb.	.06½ – .07	.07¼ – .07½
Salammoniac, gray, granular	lb.	.08 – .08¼	.08½ – .08¾
Salsoda	100 lb.	1.20 – 1.40	1.45 – 1.60
Salt cake (bulk)	ton	25.00 – 27.00	
Soda ash, light, 58 per cent flat, bags, contract	100 lb.	1.60 – 1.67	2.00 – 2.25
Soda ash, light, 58 per cent flat, bags, resale	100 lb.	1.75 – 1.80	1.85 – 2.35
Soda ash, dense, in bags, resale	100 lb.	1.85 – 1.90	1.95 – 2.40
Sodium acetate	lb.	.07½ – .07¾	.08 – .08½
Sodium bicarbonate	100 lb.	1.75 – 1.85	1.90 – 2.30
Sodium bichromate	lb.	.07½ – .07¾	.08 – .08½
Sodium bisulphate (nitre cake)	ton	4.50 – 4.60	4.65 – 5.50
Sodium bisulphite powdered, U.S.P.	lb.	.04¼ – .04½	.04⅜ – .05½
Sodium chlorate	lb.	.06¾ – .07	.07¼ – .07½
Sodium chloride	long ton	12.00 – 13.00	
Sodium cyanide	lb.	.19½ – .21	.21½ – .25
Sodium fluoride	lb.	.09½ – .09¾	.10 – .10½
Sodium hydroxide (caustic soda) solid, 76 per cent flat, drums, contract	100 lb.	3.35 – 3.40	3.75 – 4.00
Sodium hydroxide (caustic soda) solid, 76% flat, drums, resale	100 lb.	3.50 – 3.60	3.65 – 4.00
Sodium hydroxide (caustic soda), ground and flake, contracts	100 lb.	3.80 – 3.90	4.25 – 4.40
Sodium hydroxide (caustic soda) ground and flake, resale	100 lb.	4.00 – 4.15	4.40 – 4.60
Sodium hyposulphite	lb.	.02½ – .02¾	.03 – .03½
Sodium nitrite	lb.	.09 – .09¼	.09½ – .10

Sodium potassium tartrate (Rochelle salts)	lb		.18 – .21
Sodium prussiate, yellow	lb.	.21¼ – .21½	.21¾ – .22
Sodium silicate, (40 deg. in drums)	100 lb.	1.25 – 1.30	1.35 – 1.50
Sodium silicate, (60 deg. in drums)	100 lb.	2.25 – 2.40	2.45 – 2.75
Sodium sulphate, crystals (glaubers salt)	100 lbs.	.85 – .95	1.00 – 1.40
Sodium sulphide, fused, 60-62 per cent (conc.)	lb.	.04 – .04¼	.04½ – .05
Sodium sulphite, crystals	lb.	.03½ – .03⅝	.03⅞ – .04¼
Strontium nitrate, powdered	lb.	.09½ – .10	.10¼ – .12
Sulphur chloride, yellow	lb.	.04½ – .05	.05½ – .06
Sulphur, crude	ton	18.00 – 20.00	
Sulphur dioxide, liquid, cylinders extra	lb.	.08 – .08½	.09 – .10
Sulphur (sublimed), flour	100 lb.		2.25 – 3.10
Sulphur, roll (brimstone)	100 lb.	2.00 – 2.15	2.20 – 2.70
Talc—imported	ton	30.00 – 40.00	
Talc—domestic powdered	ton	18.00 – 25.00	
Tin bichloride	lb.	.11 – .11½	.11½ – .11¾
Tin oxide	lb.		.43 – .45
Zinc carbonate	lb.	.14 – .14½	.14¾ – .15½
Zinc chloride, gran	lb.	.07 – .07½	.07¼ – .08
Zinc cyanide	lb.	.42 – .44	.45 – .47
Zinc oxide, XX	lb.	.07½ – .08	.08¼ – .08½
Zinc sulphate	100 lb.	2.75 – 3.00	3.05 – 3.30

Coal-Tar Products

NOTE—These prices are for original packages in large quantities f.o.b. N.Y.:

Alpha-naphthol, crude	lb.	$0.90 — $0.95
Alpha-naphthol, refined	lb.	1.05 — 1.10
Alpha-naphthylamine	lb.	.28 — .30
Aniline oil, drums extra	lb.	.16 — .17
Aniline salts	lb.	.22 — .24
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Anthracene, 80%, imported in drums, duty paid	lb.	.65 — .70
Benzaldehyde U.S.P.	lb.	1.25 — 1.35
Benzene, pure, water-white, in drums (100 gal.)	gal.	.30 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.28 — .32
Benzene, 90%, in drums, resale	gal.	.37 — .40
Benzidine, base	lb.	.85 — .90
Benzidine sulphate	lb	.75 — .80
Benzoic acid, U.S.P.	lb.	.72 — .75
Benzoate of soda, U.S.P.	lb.	.57 — .65
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.55 — .60
Beta-naphthol, tech	lb.	.25 — .26
Beta-naphthyla mine, technical	lb.	1.00 — 1.25
Carbazol	lb.	.75 — .90
Cresol, U. S. P., in drums (100 lb.)	lb.	.14 — .20
Ortho-cresol, in drums (100 lb.)	lb.	.18 — .22
Cresylic acid, 97–99%, straw color, in drums	gal.	.60 — .65
Cresylic acid, 95-97%, dark, in drums	gal.	.55 — .58
Cresylic acid, 97%, resale	gal.	.90 — .95
Dichlorbenzene	lb.	.07 — .09
Diethylaniline	lb.	.50 — .60
Dimethylaniline	lb.	.39 — .41
Dinitrobenzene	lb.	.20 — .22
Dinitroclorbenzene	lb.	.22 — .23
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.32 — .34
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.25 — .30
Dipnenylamine	lb.	.54 — .56
H-acid	lb.	.75 — .80
Meta-phenylenediamine	lb.	.90 — 1.00
Monochlorbenzene	lb.	.08 — .10
Monoethylaniline	lb.	.95 — 1.10
Naphthalene crushed, in bbls	lb.	.06 — .06½
Naphthalene, flake	lb.	.06 — .06

Naphthalene, balls	lb.	$0.07 —	$0.07½
Naphthionate of soda	lb.	.58 —	.65
Naphthionic acid, crude	lb.	.65 —	.70
Nitrobenzene	lb.	.10 —	.12
Nitro-naphthalene	lb.	.30 —	.35
Nitro-toluene	lb.	.15 —	.17
N-W acid	lb.	1.20 —	1.30
Ortho-amidophenol	lb.	2.25 —	2.30
Ortho-dichlor-benzene	lb.	.17 —	.20
Ortho-nitro-phenol	lb.	.85 —	.90
Ortho-nitro-toluene	lb.	.10 —	.12
Ortho-toluidine	lb.	.12 —	.14
Para-amidophenol, base	lb.	1.20 —	1.25
Para-amidophenol, HCl	lb.	1.25 —	1.30
Para-dichlorbenzene	lb.	.17 —	.20
Paranitroaniline	lb.	.72 —	.80
Para-nitrotoluene	lb.	.55 —	.65
Para-phenylenediamine	lb.	1.50 —	1.55
Para-toluidine	lb.	.85 —	.90

Industrial

Financial, Construction and Manufacturers' News

Industrial Developments

LEATHER—The Hiteman Leather Co., West Winfield, N. Y., has adopted an overtime working schedule at its local tannery. Maximum production is being maintained.

The Tunkhannock Tannery, Tunkhannock, Pa., is operating at full capacity, and has recently advanced the wage scale 10 per cent, making the second increase within the past few months. A full working force is employed.

The Standard Kid Co., Wilmington, Del., is advancing production at its tannery to a basis of 800 dozen daily, as compared with a former output of 600 dozen. The working force is being increased.

The Chain Leather Co., Peabody, Mass., operating on contract account, is maintaining active production at its tannery, and has recently placed a new hide house and other plant buildings in service. The working force is being held at close to normal.

RUBBER — The Republic Rubber Co., Youngstown, O., has commenced the manufacture of pneumatic tires at its local mill, and plans to develop a daily output of about 1,000 such tires at an early date. The company is also maintaining production at a high point at its mechanical rubber goods departments, and new monthly sales records are being established.

The mechanical rubber goods department of all mills at Akron, O., are running at full capacity, with full working forces. The majority of plants expect to maintain this schedule for an indefinite period. A number of tire-manufacturing plants are arranging for an increase in the present operating schedule.

The Lee Tire & Rubber Co., Conshohocken, Pa., is maintaining a high production program at its local mill, giving employment to a regular working force.

OIL—The Marland Refining Co., Ponca City, Okla., is advancing operations at its oil refinery. A new cracking plant is being completed with a capacity of about 1,800 bbl. of gas oil per day, and will increase the gasoline output about 25 per cent. It will be placed in service at an early date.

The Merritt Oil Co., operating in the Big Muddy Field, Wyo., a subsidiary of the Midwest Refining Co., Denver, Colo., has advanced production to a basis of 3,000 bbl. per day. The parent organization is taking a greater output from the Salt Creek Field, advancing capacity from 60,000 to 80,000 bbl. daily, gross.

IRON AND STEEL—The McKinney Steel Co. has blown in its blast furnace at Scottsdale, Pa., following a shut-down for about 24 months. The plant has a daily capacity of 350 tons and will be brought up to this point at an early date. Employment will be given to approximately 200 men.

The Pulaski Furnace Co., Pulaski, Va., has blown in its local blast furnace, following the reopening of its mines, quarries and coke ovens. Employment will be given to more than 250 men.

The American Steel & Wire Co. is preparing to operate at all of its Farrell mills in the vicinity of Sharon, Pa.

The Bourne-Fuller Co., Cleveland, O., has advanced production to a 100 per cent capacity basis at its mills.

All steel mills in the Birmingham, Ala., district are now running on a double turn, with extra working forces.

The American Swedo Iron Co., Danville, Pa., has inaugurated a night shift at its local mills, giving employment to a large increased working force. It is purposed to double the output.

Plants of the United States Steel Corporation in the Youngstown, O., district have advanced operations to better than 90 per cent of capacity. The majority of independent mills in this section are running in excess of 80 and 85 per cent.

A total of 230 blast furnaces are now operating in the eastern Pennsylvania district, the largest number for a year or more past.

At Joliet, Ill., 18 blast furnaces out of a total of 27 are now in operation. Independent companies in this section are running on a basis of from 70 to 75 per cent of normal.

The Gulf States Steel Co., Gadsden, Ala., is operating at 4 of its 6 open-hearth furnaces.

The National Tube Co., Lorain, O., has advanced operations to practically 100 per cent at its local mills.

The Trumbull Steel Co., Warren, O., is running at close to full capacity at its plant, with regular working force.

METALS — The Davis-Daly Co., Butte, Mont., is increasing production at its copper and silver properties, with monthly average totaling 21,000 tons to the smelter at East Butte. Employment is being to more than 300 men.

The Utah Copper Co., Salt Lake City, Utah, has commenced operations at the first unit of its Magna mill, which has been remodeled and improved. The unit will have a capacity of 1,000 tons, and will be supplemented by two additional units at an early date; the plant will have a total of 12 units, with rated output of more than 12,000 tons daily. The Arthur mill of the company is on the active list, running at 15,000 tons per day.

Foundries at Wrightsville, Pa., have advanced the wages of employees 5 per cent, effective Nov. 15, with a similar increase agreed upon at the first of the year. Among the plants affected are the Riverside Foundry Co., and the Susquehanna Casting Co., both running close to normal.

The United Engineering & Foundry Co. has resumed production at its Todd foundry, Youngstown, O., after a shut-down since May, 1918.

The Nevada Consolidated Copper Co. is running its McGill, Nev., smelter on the basis of 2,400 tons of copper ore per day, divided among 6 operating units. This will be advanced to 15 units in service shortly after the first of the year, with daily capacity of 6,000 tons.

Construction and Operation

Arizona

SUPERIOR—The Magma Copper Co. is perfecting plans for the erection of a new smelting plant at its properties. Other extensions and improvements will also be made.

California

MONOLITH—The Monolith Portland Cement Co. has inaugurated a program of extensions and improvements at its plant to increase the capacity to 3,000 bbl. per day. Additional equipment will be installed.

SIERRA CITY—E. C. Klinker and associates have taken over the Bigelow quartz properties, and plan for extensive production. Machinery will be installed, including equipment recently obtained from the Monarch Mine, in this same district. The Bigelow property has been inactive for some time past.

LOS ANGELES—The Shell Oil Co., San Francisco, has awarded a contract to the William A. Heitman Construction Co., 900 Merritt Bldg., Los Angeles, for the erection of the initial buildings for its new refining plant on a tract of land recently acquired at Wilmington, Los Angeles Harbor. The work will consist of a main refinery, pumping plant, stills, tanks, power house and a number of mechanical buildings, estimated to cost close to $5,000,000, with machinery.

Connecticut

WATERBURY—The Connecticut Brass Co., Watertown Rd., has plans nearing completion for the erection of a new 1-story brass foundry. Work will be commenced at an early date.

Georgia

AUGUSTA—The Hills Molasses Mixture Co., 19 Jackson St., recently organized, has obtained a local building and will soon commence the installation of machinery for the manufacture of insecticides for the destruction of the cotton boll weevil and other service. A list of equipment has been prepared. Frank H. Barrett is president.

GRIFFIN—Fire, Nov. 9 destroyed a portion of the fertilizer works of Gossett & Sons, with loss estimated at about $20,000. It is planned to rebuild.

Indiana

INDIANAPOLIS—The Republic Creosoting Co., 1614 Merchants' Bank Bldg., has plans in progress for the erection of two 1-story additions to its plant at Maywood, 82x107 ft. and 40x40 ft., respectively. A new still, condenser and other equipment will be installed. Batchelder & Scales, 426 Board of Trade Bldg., are architects. Peter C. Reilly is president.

INDIANAPOLIS—The Puritan Bed Springs Co., 902 Kentucky Ave., will rebuild the portion of its enameling works, destroyed by fire, Nov. 8.

Kentucky

LOUISVILLE—The Standard Sanitary Mfg. Co., 6th and Shipp Sts., has plans nearing completion for the erection of a 1-story addition to its plant, 55x325 ft., to be used for the most part for the enamel department at the works, estimated to cost about $75,000, including equipment. It will give employment to an increased working force of about 125 men.

OWENSBORO—The Bolger & Medley Co. has plans in progress for the establishment of a new local plant for the manufacture of face brick, hollow tile and other burned clay products. Work will begin at an early date.

Louisiana

NEW ORLEANS—The Atlantic Paint Co. has plans under way for the construction of a new 2-story brick plant, 30x140 ft., to replace its factory recently destroyed by fire. A general contract for the building will soon be let.

NEW ORLEANS—A. P. Orrick, 410 Chartres St., is making inquiries for machinery for the manufacture of soap and special soap shapes, to be installed in a local building.

SWARTZ—The Atlas Oil Co. has authorized the immediate preparation of plans for the erection of a new gasoline-refining plant, on the site of its former works, recently destroyed by fire with loss of about $100,000, including equipment. The new structure will cost approximately a like amount.

Maine

MILLINOCKET—The Great Northern Paper Co. has work in progress on a new 1-story building at its plant, 60x180 ft., estimated to cost about $25,000. C. P. Crowell and W. S. Lancaster, Exchange Bldg., Bangor, Me., are architects.

Maryland

SECURITY—The Security Cement & Lime Co., 116 West Washington St., Hagerstown, has commenced the erection of a new 1-story addition to its local cement mill for general increase in production. Other extensions will be made at the plant, including the installation of additional machinery. John Porter is general manager.

BALTIMORE — The American Oil Co., American Bldg., has taken title to the shipyard of the Henry Smith Shipbuilding Co., Curtis Bay, comprising about 10 acres of land, for a consideration of about $90,000, and will use the site for a new storage and distributing plant. Plans are under way for the initial buildings, including steel tanks with a total capacity of 2,500,000 gal. and which later will be increased to 10,000,000 gal. A factory will also be established for the manufacture of soaps, greases and kindred specialties. The new plant is estimated to cost approximately $500,000, including equipment.

CAMBRIDGE—The Dorchester Lime & Fertilizer Co., Trenton St., is completing plans for the erection of two new 1-story plant buildings, 100x150 ft. and 60x100 ft., to replace its plant recently destroyed by fire. A complete mixing and grinding unit will be installed, with capacity of about 20 tons per hour. The fire loss was approximately $65,000, and the new work will cost a like amount. Lloyd Webster is president.

Massachusetts

BROCKTON—The Brockton Gas Co., 40 Centre St., has foundations under way for an addition to its artificial gas plant on Grove St., estimated to cost about $100,000, including equipment.

EVERETT—The Beacon Oil Co., Beacham St., will commence the immediate erection of a 1-story building on Charles Court, 50x50 ft., for general operating service.

Michigan

PETOSKEY—The Petoskey Portland Cement Co. has tentative plans under consideration for enlargements in its plant for considerable increase in capacity. A number of buildings will be constructed, estimated to cost close to $500,000, including machinery. J. C. Buckbee, First National Bank Bldg., Chicago, Ill., is consulting engineer.

DETROIT—Fire, Nov. 15, destroyed the local distributing plant of the Huron Portland Cement Co., Atwater and Riopelle Sts., with loss estimated at about $250,000, including building, equipment and stock. Headquarters of the company are in the Ford Bldg.

BAY CITY—The City Council has commenced excavations for a new filtration plant at the municipal waterworks, estimated to cost about $1,500,000, with equipment. The Frazier-Elm-Sheal Co., Illuminating Bldg., Cleveland, O., is engineer.

Mississippi

MAGNOLIA—The Magnolia Cotton Oil Co. has plans under way for the erection of a new 1-story plant.

Missouri

HILLSBORO—The Apt Co., 3620 West Pine Blvd., St. Louis, Mo., will build a 1-story foundry in connection with its proposed local works for the manufacture of railroad specialties, castings, etc. W. E. Apt is president.

GRANITE CITY—The Union Starch & Refining Co., Edinburg, Ind., has taken title to the local plant of the Temtor Corn & Fruit Products Co., recently acquired for a consideration said to be about $1,000,000, and will take possession at once. Improvements will be made and operations commenced at an early date for the manufacture of glucose and other kindred products. The purchasing company will increase its working capital, and will establish headquarters at the local plant. It is purposed to discontinue operations at the Erinburg works.

Nevada

BATTLE MOUNTAIN—The Cortez Silver Co. has construction under way on a new mill with capacity of 100 tons per day, and plans to have the unit ready for service in the near future. The output will be increased to 150 tons with the installation of additional machinery shortly thereafter.

New Jersey

NEW BRUNSWICK—The Public Service Gas Co., Public Service Terminal, Newark, has acquired a tract of about 48 acres of property on the Raritan River, Raritan Township, as a site for a new artificial gas plant, with gross capacity of about 10,000,000 cu.ft. per day. It is estimated to cost in excess of $250,000.

NEWARK—The Essex County Highway Department is planning for the installation of a chemical laboratory for testing service. Space in a local building has been arranged for the purpose.

PISCATAWAY—The Middlesex Hollow Tile Co., 215 Rector St., Perth Amboy, recently organized with a capital of $100,000, has acquired the local plant of the Kelso Clay Products Co., and will use the works for the production of hollow tile. Operations will be placed under way at once. John G. Fritzinger, formerly connected with the National Fireproofing Co., heads the new organization. Other officials are John H. and C. E. Fritzinger.

GLOUCESTER CITY—The City Council is arranging a bond issue of $80,000, the larger portion of the proceeds to be used for the installation of a filtration plant at the municipal waterworks. A contract will be awarded in the near future.

New York

BATAVIA—The plant of the Batavia Rubber Co. has been acquired at a receiver's sale by the Taylor, Armitage & Eagle Co., 120 Broadway, and the Fred Stearns Co., 1832 Broadway, both of New York. The new owners have made a joint agreement to operate the plant for the manufacture of automobile tires, and will place the works in service at an early date. Improvements will be made.

RICHMOND HILL, L. I.—The Unique Leather Goods Co., 125th St. and Jamaica Ave., has filed plans for the erection of a new 2-story plant, 90x128 ft., estimated to cost about $85,000. William Higginson, 15 Park Row, New York, is architect.

BATAVIA—The United States Gypsum Co., 205 West Monroe St., Chicago, Ill., has taken title to a tract of gypsum property at Oakfield, near Batavia, totaling about 1,000 acres, and plans for the early development of the site. It is said that a new plant will be built at a later date.

NEW YORK—The Board of Trustees, Columbia University, Morningside Heights, has plans nearing completion for the proposed new chemical engineering and chemistry building at the institution. McKim, Mead & White, 101 Park Ave., are architects.

North Carolina

CHARLOTTE—The Aiken Mfg. Co., 728 East 7th St., recently organized with a capital of $100,000, has acquired a local plant for the manufacture of polishes and kindred specialties. The present factory will be enlarged and additional equipment installed at an early date. L. S. Sloop is president.

Oklahoma

SAND SPRINGS—The Mid-Chemical Co. has perfected arrangements for a local plant for the manufacture of chemicals and chemical byproducts. O. E. Oesterlie, Henryetta, Okla., is one of the heads of the company.

SAND SPRINGS—The du Pont Powder Co. has broken ground for the construction of a local plant for the manufacture of a line of powder specialties.

Pennsylvania

PITTSBURGH—The Metal & Thermit Corp., 120 Broadway, New York, manufacturer of metals, alloys, etc., is taking bids for the erection of a new 2-story plant, 40x100 ft., on Fayette St. H. D. Kelly, 801 Hillsboro Ave., is local representative.

PHILADELPHIA—The Abrasive Co., Tacony and Fraley Sts., manufacturer of grinding wheels and other abrasive products, has awarded a contract to the Pittsburgh-Des Moines Steel Co., 30 Church St., New York, for the erection of a 1-story addition.

WILKES-BARRE—A 1-story pressing and drying building at the plant of the du Pont Powder Co., Oliver Mills, near Wilkes-Barre, was destroyed by fire, Nov. 16, caused by an explosion.

FULLERTON—The Lehigh-Fuller Co., has tentative plans under way for the rebuilding of the portion of the foundry at its machinery manufacturing plant destroyed by fire, Nov. 13, with loss estimated at about $35,000, including equipment.

PHILADELPHIA—The American Insulation Co., Stokley St., manufacturer of asbestos products, has awarded a contract to the William Steele & Sons Co., 1600 Arch St., for the erection of a 1-story building at its plant to cost about $25,000.

CEMENTON—The Whitehall Portland Cement Co. will build an addition to its storage and distributing plant, and make other mill improvements.

PHILADELPHIA—The Pennsylvania Sugar Co., Delaware Ave., has plans under way for the erection of a new group of buildings at its local refining plant.

South Carolina

CLOVER—The Clover Cotton Oil & Gin Co. has been organized by J. F. Pursley, for the operation of a local mill for the production of cotton oil and fertilizer products. Plans are in progress for the plant, to total about 5,000 sq.ft. of floor space and to be equipped for a daily output of 100 tons of material.

Tennessee

CHATTANOOGA—The Gager Lime & Mfg. Co. is planning for the installation of additional equipment at its plant, including washing machinery, crushers, etc. M. P. Kenney is secretary.

Texas

CISCO—The local oil refinery of the Liberty Oil Co. has been acquired by new interests, headed by L. H. Christman, Dallas. The new owners plan for immediate enlargements, including the installation of additional equipment, estimated to cost approximately $50,000. The output will be increased to 3,000 bbl. daily.

SHERMAN—The Buffalo Refining Co., recently organized, has purchased the local oil refinery of the Buffalo Products & Refining Co., with capacity of 400 bbl. per day, and will take immediate possession. Improvements will be made and the plant placed in service. F. M. Thompson and D. L. Cooke head the new organization.

HUMBLE—Fire, Nov. 12, destroyed a large portion of the local tank farm of the Gulf Production Co., with loss estimated in excess of $300,000, including equipment.

West Virginia

NITRO—The Rubber Service Laboratories, Inc., is planning for the rebuilding of the portion of its local plant, recently destroyed by fire with loss estimated at about $75,000, including equipment. B. Carl Hand is general manager.

NITRO—The Charleston Paper Mfg. Co. has work under way on a new plant, comprising the remodeling of an existing building, for a new paper mill. It is planned to install equipment at an early date.

INWOOD—The Valley Evaporating Co. has tentative plans under consideration for the rebuilding of the portion of its plant recently destroyed by fire. An official estimate of loss has not been made.

Wisconsin

RACINE—The Belle City Malleable Iron Co., is razing an existing building on local plant site, preparatory to the erection of a new 1-story annealing works, 75x153 ft., for which plans have been completed.

New Companies

KAHLBAUM-KIRBACH, INC., New York, N. Y., care of C. S. Aronstam, 120 Broadway, New York, representative, has been incorporated with a capital of $50,000, to manufacture chemicals and chemical byproducts. The incorporators are A. H. Appel, H. Pleus and F. R. Fox.

THE BARNES ZINC CO., Eighth and Union Sts., La Salle, Ill., has been incorporated with a capital of $100,000, to manufacture zinc and kindred metal products. The incorporators are C. B. O'Neil, Frank Page and Harold Beacon.

THE LITTLE FALLS CHEMICAL CO., Little Falls, N. J., has been incorporated with a capital of 1,000 shares of stock, no par value, to manufacture chemicals and chemical byproducts. The incorporators are E. C. Fox, Louis Van der Meer and Justus C. Herstein, Little Falls. The last noted represents the company.

THE GENERAL EXPLOSIVES CO., Wilmington, Del., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, has been incorporated under state laws to manufacture explosives, powder, etc., with capital of $1,000,000.

THE KEN OIL CORP., Binghamton, N. Y., has been incorporated with a capital of $50,000, to manufacture oil products. The incorporators are T. G. O'Brien, J. L. Weir and H. D. Ballard. The company is represented by Mangan & Managan, Binghamton.

THE STEVENS PAPER MILLS, INC., Rainbow, Windsor, Conn., recently incorporated, has been organized with a paid in capital of $50,000, to manufacture paper products. C. N. Stevens, New Rochelle, N. Y., has been elected president; and George C. Russell, Hartford, Conn., vice-president.

THE ATTOYAC OIL CO., Henderson, Tex., has been incorporated with a capital of $25,000, to manufacture petroleum products. The incorporators are O. S. Rogers, R. T. Forman and A. C. Wylie, all of Henderson.

THE NELSON PRODUCTS CO., Room 637, 111 West Washington St., Chicago, Ill., has been incorporated with a capital of $25,000, to manufacture colors, chemicals, etc. The incorporators are George C. Hager, R. D. Clay and H. C. McVeigh.

THE LIQUID LIGHTNING CO., Portland, Ore., has been incorporated with a capital of $5,000, to manufacture compounds for batteries and other purposes. W. A. Carter, 1212 Gasco Bldg., Portland, is the principal incorporator.

THE BUCKEYE COPPER CO., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., has been incorporated under Delaware laws with capital of $20,000,000, to produce refined copper and other metals.

THE SEPOY COLOR & CHEMICAL CO., Jersey City, N. J., care of the Corporation Trust Co., 15 Exchange Pl., Jersey City, representative, has been incorporated with a capital of 1,500 shares of stock, no par value, to manufacture colors, chemicals and chemical byproducts.

THE PURITY CHEMICAL CO., Boston, Mass., has filed notice of organization to manufacture chemicals and chemical byproducts. The company is headed by Milton Ackerman and Ralph A. Bowen, 11 Stover St., Boston.

THE A. B. MASSA PAPER CORP., New York, N. Y., care of Knox & Dooling, 37 West 43rd St., New York, representatives, has been incorporated with a capital of $25,000, to manufacture paper products. The incorporators are A. B. and L. V. Massa.

THE ELECTRO-PLATING CO., Huntington, W. Va., has been incorporated with a capital of $5,000, to operate a metal-plating works. The incorporators are Louis and B. Klamer, Maurice Rosen and I. Benjamin Romer, all of Huntington.

THE EDWARDSVILLE CHEMICAL CO., Troy Rd. and 3rd St., Mahler Heights, near Edwardsville, Ill., has been incorporated with a capital of $5,000, to manufacture chemicals and chemical byproducts. The incorporators are Charles F. Scholl and Edward Koenig.

THE ARKANSAS-MARUCOPA OIL CO., Fulton, Ky., has been incorporated with a capital of $75,000, to manufacture petroleum products. The incorporators are W. E. Simmons, W. W. Gourley and J. T. Linton, all of Fulton.

THE BETHEL TANNING CO., INC., Bethel, Conn., recently incorporated, has been organized with headquarters at 146 Center St., to manufacture leather. Howard E. Mackenzie has been elected president; F. H. Judd, vice-president; and Charles H. Hart, secretary and treasurer.

THE COATING SPECIALTIES CO., New York, N. Y., care of the United States Corporation Co., 65 Cedar St., New York, has been incorporated under Delaware laws with capital of $50,000, to manufacture paints, varnishes and kindred products.

THE BERKSHIRE TALC PRODUCTS CORP., Newark, N. J., care of Harry Unger, 207 Market St., Newark, representative, has been incorporated with a capital of $125,000, to operate talc properties and manufacture refined talc products. The incorporators are Harold Shuster, Frederick G. Rose and George E. Ebehalt.

THE HUB CHEMICAL CO., Boston, Mass., has filed notice of organization to manufacture and deal in chemicals and chemical byproducts. The company is headed by John B. Lewis, 54 Thayer St., Boston.

WALTER SHUTTLEWORTH, INC., New York, N. Y., care of R. S. Nichols, 141 Broadway, New York, representative, has been incorporated with a capital of $150,000, to manufacture paper products. The incorporators are E. G. and W. E. Shuttleworth, and H. Comiskey.

THE R. L. GLASSON CHEMICAL CO., Seymour, Ind., care of the Colonial Charter Co., Ford Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws with capital of $100,000, to manufacture chemicals and chemical byproducts. The incorporators are Reuben Glasson and Charles F. Quade, both of Seymour.

THE STRATFORD CO., Morganville, N. J., care of James F. Farrell, Morganville, representative, has been incorporated with a capital of $1,000,000, to manufacture arsenic acid and other acids and chemicals. The incorporators are Julius Midas, Peter von der Hyde and James L. Ryan.

THE FIT FORM MFG. CO., New York, N. Y., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., has been incorporated under Delaware laws with capital of $1,250,000, to manufacture bottles and other glass containers. The incorporators are William F. Dermott, New York; Patrick M. Kelly, Jersey City, N. J.; and Theodore L. Harrison, Ridgefield Park, N. J.

THE INTERSTATE RUBBER CO., New York, N. Y., care of Nathan Permut, 82 Duane St., New York, representative, has been incorporated with a capital of $20,000, to manufacture rubber products. The incorporators are G., A., and J. E. Conklin.

THE AMERICAN ELECTRO-PLATING WORKS, INC., Somerville, Mass., has been incorporated with a capital of 100 shares of stock, no par value, to operate a metal plating plant. John J. Walsh, Ames Bldg., Boston, is treasurer and representative.

THE GREENWICH CHEMICAL CO., New York, N. Y., care of the United States Corporation Co., 65 Cedar St., New York, representative, has been incorporated under Delaware laws, with capital of $350,000, to manufacture chemicals and chemical byproducts. The principal incorporator is Samuel C. Wood, New York.

THE TILE PRODUCTS, INC., New York, N. Y., care of Delamarter & Morrison, 140 Nassau St., representatives, has been incorporated with a capital of $100,000, to manufacture ceramic tile and other kindred named clay products. The incorporators are F. Sellar, E. L. Hendrickson and H. A. [illegible]

Capital Increases, etc.

THE EGYPTIAN LACQUER MFG. CO., Passaic Ave., Kearny, Newark, N. J., has filed notice of increase in capital from $360,000 to $720,000, for proposed expansion.

THE UNION PAINT & CHEMICAL CO., Detroit, Mich., has filed notice of dissolution under state laws.

THE ALASKA CHEMICAL CO., 113 West 27th St., New York, N. Y., has filed notice of increase in capital to $500,000, for proposed expansion.

THE PENNSYLVANIA INDEPENDENT OIL CO., INC., Philadelphia, Pa., care of J. H. Sherman & Co., Bulletin Bldg., Philadelphia, bankers, is disposing of a stock issue of $440,000, a portion of the proceeds to be used for expansion.

THE VIRGINIA-CAROLINA CHEMICAL CO., Richmond, Va., has arranged for an increase in capital to $68,000,000, for general expansion and financing.

THE SOUTHERN PAPER CO., Moss Point, Miss., is arranging for a bond issue of $1,500,000, a portion of the proceeds to be used for expansion.

THE HARDY CHEMICAL CO., Norwalk, Conn., has filed a preliminary certificate of dissolution under state laws.

THE PETROLEUM OIL CO., Anderson, S. C., is arranging for an increase in capital to $100,000, for proposed expansion. Charles A. Gambrill is president.

THE MAGNOLIA PETROLEUM CO., Galveston, Tex., operating oil refineries, has called a meeting of stockholders, Dec. 2 to approve an increase in capital from $120,000,000 to $180,000,000, a portion of the proceeds to be used for expansion.

The referee in bankruptcy for the CHOAT OIL CO., South Robinson St., Oklahoma City, Okla., has arranged for the sale of the refinery of the company, rated at a capacity of 2,000 bbl. per day.

Manufacturers' Catalogs

THE CUTLER STEEL CO., Pittsburgh, Pa., in Bulletin 221 gives a general description of Duraloy, including the development, composition and characteristics, physical properties, strength at high temperatures, machining qualities, welding qualities, oxidation and heat resistance, and corrosion and abrasion resistance.

THE BRISTOL CO., Waterbury, Conn., has issued two new publications: Catalog 1401 contains 68 pages on Pyrometers, while Bulletin 311 contains 12 pages on Bristol's Class II Recording Wet- and Dry-Bulb Thermometers.

THE HOLDECK ENGINEERS CO., Marshall Bldg., Cleveland, O., has issued a bulletin on pulverized coal as applied to the malleable iron and air furnace iron industry.

THE CALORIZING CO. OF PITTSBURGH, PA., calls attention to Bulletin 2, on Calite Castings, for use in high temperatures. Calite castings are made under patents of the General Electric Co. at its Lynn, Mass., foundry and are sold by the Calorizing Co. of Pittsburgh. This 16-page booklet gives interesting illustrations and descriptive matter on the reason for Calite, the high-temperature range, why it lasts, resistance to corrosive gases, strength, physical properties, uses, etc.

B. F. STURTEVANT CO., Hyde Park, Boston, Mass., has published Bulletin 299, on unit driers. This type of drier consists of a motor-driven fan, the air from which passes over heater coils and is then discharged into a cabinet. Practically any desired temperature and velocity of air can be obtained for the correct drying of a particular material. These driers are made in various sizes, from the size which may be set on a bench to the size into which may be wheeled a number of trucks holding several trays of the material to be dried. Where the material is of such a nature that trays are not necessary, suitable methods of suspension are fitted into the cabinet accordingly. Copy of this bulletin will be sent on request.

THE VITREFRAX CO., Los Angeles, Calif., announces a new publication entitled "The Irreducible Volume." After a general description of Vitrefrax and the scope of the Vitrefrax process, there follows information on the nature and application of refractories in general and of Vitrefrax super refractories in particular.

THE CONNERSVILLE BLOWER CO., Connersville, Ind., calls attention to Bulletin 4, on rotary displacement meters.

THE LINK-BELT CO., Chicago, Ill., announces the completion of a new general catalog, No. 100, which embraces its entire line. It is the most complete book the company has ever issued, containing 932 pages, and is cloth bound. Copies can be obtained from any Link-Belt office. The catalog not only includes the complete Link-Belt line but also the products of the H. W. Caldwell & Son Co. plant of that company. The following is a brief summary of the contents covered in the catalog: Chains and wheels, power transmission machinery, bearings, hangers, take-ups, gears (machine molded or cut-tooth), clutches, pulleys, sheaves, elevator boots, buckets, casings, helicoid and other screw conveyor equipment, gates for conveyors, bins, hoppers, etc., steel apron conveyors, belt conveyors, Peck carrier, boiler plant equipment, coal tipple equipment, coal washeries, jigs, elevators, driers, coal storage, pockets, tramways, towers, locomotive coaling stations, car loaders and unloaders, portable loaders, portable belt conveyors, locomotive and crawler type cranes, grab buckets, wood grapples, etc., electric hoists, overhead cranes, telpherage, car pullers, friction hoists, power hoes, power shovels, cable haulage, sand and gravel washing equipment, revolving screens, sand separators, etc., lime-handling equipment, foundry conveyors, sand revivifiers, elevators and conveyors for glass plants, canneries, freight handling and sugar plantation and refinery machinery.

LEE B. METTLER CO., fuel efficiency engineers, Los Angeles, Calif., has issued a pamphlet entitled "In Response to a Demand." This pamphlet treats of the Mettler silicon-carbide refractory, surface-combustion burner, the surface combustion unit and the stack-damper indicator.

THE SEMENT-SOLVAY CO., Syracuse, N. Y., in a new publication tells of its progress of 30 years, of the byproduct oven and the manufacture of city gas, byproduct gas ovens, advantages of byproduct coke and gas ovens and byproduct recovery apparatus. Interesting photographs of actual plants are given, as well as the general arrangement of a byproduct gas oven plant, diagram of oven draft for single-pass regenerators and the Semet-Solvay gas flow chart

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its annual meeting in Pittsburgh, Pa., Feb. 12 to 17, 1923.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting April 3 to 7, 1923, at New Haven, Conn.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting May 3, 4 and 5, 1923, at the Commodore Hotel, New York City.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its winter meeting at Richmond, Va., Dec. 7 to 9. Headquarters will be at the Hotel Jefferson.

INTERNATIONAL CHAMBER OF COMMERCE will hold its second general meeting in Rome, Italy, March 19-26, 1923.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

NEW JERSEY CLAY WORKERS' ASSOCIATION will hold its annual meeting at the Ceramics Building, Rutgers College, New Brunswick, Dec. 12.

SOCIETY OF CHEMICAL INDUSTRY, American Section, will meet in Rumford Hall, 52 East 41st St., New York City, on Dec. 15.

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, East 41st St., New York City: Dec. 1—Society of Chemical Industry, regular meeting. Dec. 8—American Chemical Society, regular meeting. Jan. 5—American Chemical Society, regular meeting. Jan. 12—Society of Chemical Industry, Perkin Medal. Feb. 9—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting. March 9—American Chemical Society, Nichols Medal. March 23—Society of Chemical Industry, regular meeting. April 20 — Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting. May 4—American Chemical Society, regular meeting. May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting. May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.

Strengthening Our Consular Service

THERE was a time when we looked upon consuls and diplomats as a queer sort of gold-braided courtiers or pompous supernumeraries that had somehow been forced upon our government by time and Old World customs. That youthful impression was soon dissipated, however, when we were given a chance to learn something of the multifarious duties of these men who represent us in foreign lands. In reality they constitute an active field force on which we are largely dependent for furthering and protecting our commercial interests abroad. In this way they perform a day-by-day service which in its aggregate importance to our country far outweighs this occasional but widely heralded accomplishments in the field of international politics.

As a government and as individuals the world war drew us into many new international relationships. The field of our commercial activities was greatly extended and with this came a need for a broader and better understanding of foreign affairs. The consular and diplomatic services assumed a rôle of new importance. And it was the greater demand for these services that called attention to the serious handicaps under which our representatives are laboring. Unfortunately their organization is largely on a pre-war basis—entirely inadequate to meet the pressing requirements of the government alone without giving any attention to private or commercial interests. Furthermore, the salary scales are pitifully low. For instance, diplomatic secretaries acting as counselors of embassies such as those in London or Paris receive a maximum annual salary of $4,000 and important secretarial positions are filled by men to whom the government can pay but $2,500 to $3,000. The result is that these officials, even down to the lowliest attaché, must be recruited from the ranks of men of independent means. It is a difficult task, therefore, to find a sufficient number of men who are qualified to carry out effectively the responsible and highly important work of these positons—and at the same time are willing to make so severe a personal sacrifice.

For some reason or other the law has separated the consular and diplomatic services into what has been described as "watertight compartments." Transfer from one branch to another has been made impossible: not even in an emergency could a well-qualified diplomatic secretary take over the responsibilities of a consular post. So it goes. Benefits to be derived from efficient co-ordinated administration must be withheld simply because of an antiquated law that has long since outgrown its usefulness.

These three defects in our present system—organization, personnel and compensation—can be remedied in a large measure by legislation now pending in Congress. The bills introduced by Representative J. J. ROGERS have been designed to strengthen and modernize the entire field forces of the Department of State. They provide for a reclassification and reorganization of the consular and diplomatic services. A co-ordinated plan of administration offers possibilities for flexible and efficient service and, finally, salaries have been raised to a respectable standard. The bills endeavor to do this without a radical extension of government service or an extravagant appropriation of government funds. Rather it is proposed to put these services on a directly business-like basis so that the foreign affairs of governmental and private interest may be completely and efficiently handled. Surely such a program is worthy of the support of all who are interested in furthering American business abroad.

Benjamin Silliman And Yale's New Laboratory

HISTORIC significance is given to the date that has been chosen by Yale University for the dedication of the new Sterling chemistry laboratory. It seems that on April 4, 1804, the first lecture ever given on chemistry in Yale College was delivered by BENJAMIN SILLIMAN, SR. In commemoration of that event Yale's magnificent new laboratory will be formally dedicated on April 4, 1923, during the spring meeting of the American Chemical Society in New Haven.

It is interesting to trace the influence of SILLIMAN on the development of American chemistry. For 51 years he held the chair of chemistry and natural philosophy in Yale. Probably more than any other one man in America he served to popularize science, particularly chemistry and geology, and to interest and instruct thousands of persons outside the college walls. He traveled all over the United States during a period of 20 years, lecturing on scientific subjects to large audiences. In Boston more than fifteen hundred persons paid admission to a series of evening lectures; and the capacity of the hall being exceeded by the demands, he gave a series of afternoon lectures as well.

Professor SILLIMAN was never known as a great investigator and researcher. What he did was thorough; but his great service was in bringing science to the people, in stimulating an interest in the subject in his students and in all who heard him lecture. Coming at the very beginning of our life as a nation, there was need for just such service. As founder and editor of the *American Journal of Science*, he laid the foundation for other journals devoted to the physical sciences. It is due more to Professor SILLIMAN than to any other man that the Sheffield Scientific School of Yale University was founded. Starting with scanty funds and two professors, both of whom were teachers of chemistry, the value of the institution brought forth the liberal contributions of JOSEPH E. SHEFFIELD, thereby insuring the future of this work. BENJAMIN SILLIMAN, on his retirement, turned over his work in

geology to the elder DANA, who was his pupil and who married his daughter. His chemistry courses went to his son, BENJAMIN SILLIMAN, JR., who maintained the high standards of his father and added his part in building up a strong department.

It is interesting to note that Professor SILLIMAN as a student in Yale College had no intention of becoming a scientist. Returning to New Haven at the age of 20, he took up the study of law and soon after was made tutor in Yale College. Near the close of his course in law President DWIGHT invited him to become professor of chemistry and natural philosophy, offering him time and assistance for the necessary study and preparation. SILLIMAN then spent two winters in Philadelphia as a pupil of Dr. JAMES WOODHOUSE. There he met PRIESTLEY and was an intimate friend of ROBERT HARE. Returning to New Haven, he took up his duties, his first lecture being on April 4, 1804. In his first class were several men who became famous, one of these being JOHN C. CALHOUN, afterward Vice-President of the United States. After teaching one year, SILLIMAN obtained a leave of absence and spent several months in London and Edinburgh, attending lectures. There he met HENRY, Sir HUMPHRY DAVY and DALTON. It was during his stay in Edinburgh that he became interested in geology, an interest which developed until he became as well known as a geologist as he is as a chemist.

For 15 years Professor SILLIMAN taught and carried out his experiments in a dismal basement room below the old Lyceum on the Yale campus. It is indeed fitting and appropriate that the great Sterling chemistry laboratory, now just completed at a cost of $2,000,000 and containing every facility for teaching and for research, should be dedicated on the anniversary of the first lecture given by the first professor of chemistry in Yale and in honor of a man who was a pioneer in American science.

Steel Production as A Business Index

THE time has not yet passed when business men need to be reminded of the difference between a barometer and a thermometer. The saying "Iron is the barometer of trade" is so old that it says "iron" when the trade designation of the great bulk of the ferrous product now made is "steel." Indeed, partly because the steel ingot, sound throughout, is not yet commonly made, but more generally because much scrap develops in making finished or commercial steel products, the weight of ingots cast, commonly called in the trade "the production of steel," has for 10 years past been running at considerably more than the weight of pig iron produced.

The particular point in the adage really is that steel is a barometer rather than a thermometer—that it foretells. As a thermometer showing the current condition, portland cement, of which we make something like three barrels to a ton of steel, is much better, for steel can be and is stocked by the dealer and consumer, while cement commonly is not. Storage is difficult and is generally by the producer. There are monthly statistics of shipments by cement producers, which are an accurate and prompt index of the volume of construction occurring at the time.

The barometric point about steel is that orders are placed in advance when industrial and construction activity is going to increase. It is the orders, rather than the production, that count as a barometric index. To illustrate, there was a great 3-year period of iron and steel and general industrial activity from late in 1904 to late in 1907. The difference between orders and production was striking. In the fourth quarter of 1904 the U. S. Steel Corporation's unfilled tonnage increased 1,668,767 tons, while in the third quarter of 1907 there was a decrease of 1,178,870 tons. In October, 1907, the month after that quarter and the month of the panic, production of steel made a new high record and was at a rate more than 50 per cent greater than the rate in the fourth quarter of 1904. In 1908 there was an industrial depression. The heavy buying late in 1904 was barometric of the industrial revival then on its way, while the record production of October, 1907, was not even thermometric in showing anything as to business and industrial conditions. The case is strictly typical, not exceptional, and is selected for citation because it was a particularly big case and being before the war may be regarded as normal.

Paradox—The Valley And Its Treasure

IT WOULD BE difficult to cite a topic from the news of the day which would cause the average citizen less concern than the prevailing price of radium. A drop of $30,000 per gram in the price of radium arouses far less jubilation in his breast than would a decrease of $1 per ton in the price of coal. Nevertheless, there is an interesting story back of the recent sensational drop in the price of radium; interesting because, as a result of it, all the radium plants in this country are shut down and because it gives the wiseacres such a beautiful opportunity for whispers of profiteering, cut-throat competition, price-cutting and other shocking practices. What is the real meaning of radium at $70 a milligram?

The answer involves the well-known partners who have been convicted so often of price-fixing—Supply and Demand. It is generally understood that the carnotite deposits of Paradox Valley, Colorado, constitute the largest known source of radium in the world. The average uranium oxide content of this ore is from 1.5 to 2.8 per cent, which means that it contains about 1 milligram of radium per 500 lb. of ore. Obviously, the extraction process is tedious and expensive. Recently there have been shipped to Belgium considerable quantities of very high-grade pitchblende ore from deposits in the extreme southern part of Belgian Congo on the property of the Union Minière du Haut-Katanga, a British-Belgian company operating large copper-bearing properties in Kantanga. An extraction plant has been erected at Oolen, Belgium, to work this ore. Undoubtedly, radium can be produced from this very rich ore at a much lower cost than from carnotite ore. Hence the suspension of extraction operations in this country is the best alternative, particularly since the several companies have been able to consummate working agreements with the Belgian producers for the marketing of their product in this country, thus preserving the identity of their distributing organizations.

In view of the production costs given by H. H. BARKER, on page 1114 of this issue, it is obvious that American radium producers have taken a loss on radium produced from Colorado carnotite and sold at $70 per milligram. Perhaps this was justified by the necessity of turning stocks into available capital, or by the advertising value of a large sale, or both. The

need for working capital in the industry was a consequence of overproduction. The financial depression did not really affect the radium industry until the early part of last year. At that time, when the demand began to slacken, the manufacturers were so unwise as to continue operations too long—a repetition of mistakes previously made in other industries. The result was the largest production in the history of the industry—over 36 grams—a large part of which remained unsold, much of it held by the banks as collateral.

Such are the circumstances that have brought about a reduction in the price of radium to an unprecedented level. Apparently $70 is to be the standard price for domestic and imported material until the Belgian ore gets "leaner" and extraction costs increase. The extent of the African deposits can be determined only by continued working, but it is generally believed by experts that the occurrence of the high-grade ore is limited to a few large pockets that will eventually be exhausted, so that Paradox Valley will come into its own again.

In the meantime, here is an opportunity for philanthropists and public institutions of large means to make radium available for the treatment of cancer and other malignant diseases. The State of New York and the City of Philadelphia have each bought 2 grams for the use of their citizens and the Province of Quebec has bought 1 gram. Surely, the opportunity to make radium and its emanation more readily available to sufferers, rich or poor, should be the most important "meaning" of cheaper radium.

Hunting for Woodchucks And Shooting the Cow

ON VARIOUS OCCASIONS we have commented on the activities of the prohibition enforcement authorities in a vein that has led some of our readers to charge us with failure to give moral support to the law. Perhaps it will be worth while making our position clear.

The Volstead act is the law of the land, and as long as it is, we stand for its impartial enforcement. But the very act which provides for the abolition of alcoholic beverages provides also for the use of alcohol in the industries, and even for its encouragement in this respect. Our protest is against the activities of prohibition enforcement officers that result in the crippling of legitimate industry without practically helping to destroy the drink evil. Failure of the prohibition authorities to perform their duty has become a national disgrace that has rightly caused grave apprehension in the Executive office at Washington. Bootleggers thrive. And simultaneously with the failure to curb these violators of the law, rules and regulations against legitimate industry are multiplied.

A little reflection brings up a related question, and this is whether morally, ethically or even legally the government has the right to introduce poisons into alcohol for the purpose of enforcing prohibition by killing the man who evades the law. This puts the whole principle of attempting to enforce prohibition on a square moral and legal issue, and it leads to the one right and available method of enforcement, which is to catch and punish the offenders.

The separation of denaturants from alcohol, like moonshine distilling, is a forbidden art no matter what the denaturant may be. It *is* moonshine distilling except that denatured alcohol is employed instead of corn or other mash. It is not practiced by law-abiding manufacturers, but it is a great game for the bootleggers. It is a dangerous game, but all illicit business is dangerous.

Changing formulas or the use of vicious poisons will not stop the practice, because there is plenty of money in bootlegging and there are chemists who are willing to conduct research for bootleggers and thus to circumvent any strategem. The question they ask themselves in regard to poisons is not how deadly they may be, but rather how robust they are in their chemical structure. It is mere child's play to try to circumvent the production of beverages by shifts of this kind. Illicit distilling is one occupation, and honest manufacturing is something entirely different. The law recognizes this. Prohibition enforcement officers should, but very often they do not. The chief prohibition enforcement officer lately boasted of the decreased production of tax-paid alcohol, and cited it as evidence of prohibition activity.

We shall not discuss the rum-runners doing business off our coasts with native craft, of which the latter are proper game for the authorities, or the great quantities of alcoholic beverages smuggled in under full authority and warrant from Canada, or the liquors and intoxicants withdrawn or made in secret. They do not come from legitimate makers of varnish, soaps, perfumery, fabrics and the like. Such manufacturers would not sell alcohol denatured or normal for beverages; they are engaged in other business. They do not hide or work in secret and the risk would be too great. The illicit producers and dealers are difficult to find, but it is nevertheless the business of the authorities to find them. The worst method in the world is to make the innocent suffer for the guilty. It is like hunting for woodchucks and shooting the cow.

Poisoning alcohol does not enforce prohibition. And again we ask, Is such denaturation legal or is it not? The man who manufactures or transports alcohol as a beverage or maintains it for drinking purposes commits a misdemeanor. It is not a capital crime. He is entitled to his day in court. Whether he drinks the stuff or not, it would be illegal to shoot him. Then by what right is he poisoned?

A Task for The Chemical Division

ELSEWHERE in these columns we have called attention to the need for adequately supporting the diplomatic and consular services—those governmental agencies that are effective for promoting our foreign trade. In this connection the chemical industry has a problem that is all its own. Much of the information on chemicals that is now being sent in by the government's foreign agents is of a more or less perfunctory character and does not deal with the specific problems or commodities in which the chemical exporter is interested. In order for our industry to profit to the fullest extent from this work it is essential that the consular agents be thoroughly acquainted with the problems of our export trade in chemicals. These men should be properly instructed as to what information is desired, about what commodities and from what particular countries or districts. In other words, there is a need for a consul's chemical manual—a sort of encyclopedia of world competition in chemicals. To prepare such a volume is a task for the Chemical Division of the Department of Commerce and an opportunity for constructive service in developing a healthy foreign trade in American chemicals.

Readers' Views and Comments

European Conditions as I Saw Them

To the Editor of Chemical & Metallurgical Engineering

SIR:—Readers of *Chem. & Met.* who are my personal friends have taken particular interest in the series of articles you have been publishing on "European Conditions as I Saw Them." I have had many conversations with them, and have sought to learn their views on the articles that have already been published. Their opinions are of interest; first, because some of them are somewhat familiar with European conditions, and, second, because of their frankness in passing criticism on my own views.

Permit me to pass in review here some of their criticisms, together with brief answers thereto. Perhaps by so doing, I shall reach other *Chem. & Met.* readers who may have had similar thoughts.

1. The German economic war idea is a *deus ex machina.* I can assure you it is not. In the latter part of March I heard the expression "Wirtschaftlicher Kampf" (economic fight) from a German intellectual, an expression which he used deliberately in the course of conversation on the abnormal discrepancy between the intrinsic and selling values of German finished products. The meaning and the scope of such a war have become clearer and clearer to me the more I have talked about it with intellectuals and average citizens of Germany. This has been reinforced by my observation of German industrial conditions as compared with those in other industrial countries. My conclusion, therefore, that the German economic war was used to create an atmosphere and undercurrent of opposition to the Versailles treaty, and that the cancellation of that treaty and the *status quo ante bellum,* 1914, were offered as a condition of truce, is a normal sequence to the observations made during my trip through Europe.

2. It is not conceivable that German industrials and merchants would be willing to sell at a loss. No, they personally did not lose. Stinnes and his type have constantly grown richer since the Versailles treaty was signed. On the other hand, the masses of the people working for wages and salaries have stood the loss, by getting only a small fraction of what they should receive were they paid the due reward of their labor. A wage of less than 1.5 cents per hour for girls in a German plant, mentioned in my article published Oct. 25, was considered a fair wage in the eyes of many German industrials, just as less than $1 per week for saleswomen in a Berlin shoe store was regarded as a fair wage in the eyes of many German merchants. As to the status of German salaried people, I shall reserve comment for a subsequent article.

3. It is not conceivable that German industrials should thus exploit their own workpeople. I grant that it seems inconceivable, but so was the war. The actual facts prove that it is so.

4. Writers of many sorts—politicians, bankers, economists, amateur students of European conditions, special correspondents and professional interviewers—have written a great deal about conditions in Europe, but none of them has brought forth even a hint as to a German economic war. This is quite true, but I regard it as being due to their individual limitations as observers. Not being in any of the above classes, I observed the industrial conditions closely; and when I looked at Germans at work, I saw clearly what is typified in the cartoon reproduced in our issue for Oct. 18.

5. What has all this to do with European industrial progress? My reason for emphasizing this subject is that it seems to me to be the outstanding cause of much of the distress in Germany, which prevails generally instead of the progress I expected to find. It seems to me a fitting subject to bring into the foreground, in order that American engineers may comprehend the situation and perhaps initiate a policy that will hasten the arrival of the day when everyone will have an opportunity to contribute to industrial progress and receive his fair reward.

6. What comment or reaction do I expect from Germany? It is impossible for me to give a direct answer to this question, but I should not be surprised if *Chem. & Met.* were to receive some protests and objections to various statements that have been made. I feel that I can substantiate with details all general statements that have been made; and, furthermore, I feel that the best refutation that could be given to my statements would be official German statistics of production and export, showing what has become of the products of her industries since the signing of the Versailles treaty.

New York City. J. S. NEGRU.

Wasn't This a Public Service?

To the Editor of Chemical & Metallurgical Engineering

SIR:—At Indianapolis the members of the local section of the American Chemical Society meet at luncheon every week, at the Chamber of Commerce. Usually someone is invited to address them, and whoever speaks may count on courteous and interested attention from an intelligent and scholarly audience. The members come from near enough to Missouri to want to be informed, and if anybody has anything to say or to offer that sounds interesting they are ambitious to know all about it. Then they ask questions.

There has lately been distributed in Indianapolis a little pamphlet, telling the good citizens how whoever will may achieve great wealth by getting it from the air. A remarkable invention is announced whereby "complete union of nitrogen of the air and lignite gas, forming sulphate of ammonia—direct" may be obtained. "The United States," says the circular, "annually imports $32,000,000 of nitrogen in its various forms, and $4,000,000 of sulphate of ammonia, from which is made nitric acid, hydrochloric acid, sodium nitrate (Chilean saltpeter), soda ash, caustic soda and all the ammonias." It declares that a $50,000 investment will enable the investor to reap a profit of $1,400 daily. It provides for "the complete gasification of coal, lignite, peat or shale, the ash being the only residue." Again, "A 1,000-ton plant will give the same results that are secured from a 4,000-bbl. oil well, all without drilling or dry holes." Again, "By the use of the new process . . . it would be possible for a 2,000-ton lignite plant to

recover more than four times as much nitrate as is secured from Muscle Shoals, or, to be exact, 146,000 tons, and the plant would not cost to exceed $2,000,000." In addition, "the new process plant would be capable of producing more electrical energy than Niagara Falls and Muscle Shoals combined." And finally, "This seems to be a sure money-making proposition for any investor," etc.

Who would not grow excited over such revelations as ammonium sulphate from nitrogen and "lignite gas"? Or again, the production from ammonium sulphate of hydrochloric acid, sodium nitrate, soda ash, caustic soda and more particularly *all the ammonias*, not to speak of the wealth that is offered?

So one of the inventors and the chief promoter were invited to join the section at luncheon and to tell all about it, which they did. The members listened politely and attentively, according to their habit. But after the speakers had delivered themselves of a description of all the wonders of their boon to humanity, the questioning period began, and without harsh or unkind words the whole scheme was carefully and logically analyzed. The promoter and inventor got deeper and deeper into contradictions and entanglements, until in the end there wasn't much invention left, and the chance to make squintillions of dollars evaporated right before their eyes.

You've been talking about chemists and public service, Mr. Editor. Wasn't this a public service?

MARTIN SEYT.

British Chemical Industries

FROM OUR BRITISH CORRESPONDENT

LONDON, Nov. 17, 1922.

IN SPITE of the political upheaval, the inevitable disturbance of normal trade due to a Parliamentary general election and a certain amount of depression in the textile trades, the chemical market continues in a fairly healthy state, particularly for heavy chemicals in home markets and also as regards export. Large forward contracts are still few and far between, but now that the "period of tranquillity" policy is to have its chance, competent observers predict a further revival of confidence, and this idea of an improved outlook is reflected by a rise in the quotations for shares in the principal chemical concerns. Acetone is still almost unobtainable and other wood-distillation products are also rising appreciably in price. Croesote is a good market, partly in view of an expected demand from American and British railways.

NEW WEEKLY JOURNAL

In club circles one of the principal topics of conversation has been occasioned by the common knowledge that the Council of the Society of Chemical Industry proposes from the beginning of next year either to publish the society's journal weekly or to discontinue the Review Section; in the latter case the journal would contain only transactions and abstracts and little advertising matter. Certain parts of the present Review Section will be embodied in the new weekly, for which the title *Chemistry and Industry* is suggested. This name was decided upon after some controversy and, perhaps unfortunately, is very similar to the French journal *Chimie et Industrie.* So far, the obvious course of hiring a trained journalist to edit *Chemistry and Industry* has not been adopted and there has been much speculation as to whether a continuation of the policy of amateur technical journalism would not spell failure for a paper which, in the long run, is dependent financially upon circulation and advertisements. The right man has yet to be found, but for the next few months the editorship will be, it is understood, in the hands of Dr. Stephen Miall. It is hoped to arrange for a more extensive circulation and generally to carry out the much-discussed intention of launching a weekly section. The crux of the matter is probably the attitude of advertisers and whether they will stand for the increased rates as compared with fortnightly insertions.

THE PARLIAMENTARY ELECTION

The cry of the trading community at the moment is undoubtedly "more orders," coupled with complaints as to lack of governmental support and understanding. During the war the development of the Department of Overseas Trade on practical lines was a step in the right direction and it is considered very unfortunate that the economy axe should have affected this means of obtaining early information as to opportunities for trade overseas. There is some prospect that the new government will restore the lost activities of this department, which in the past has proved of real use to chemical manufacturers. Chemists in Parliament have been few and far between and Mr. Woolcock, the general manager of the Association of British Chemical Manufacturers, was one of those who did not seek reelection. The results just to hand show that Sir William Pearce, a member of long standing, has been defeated, but C. S. Garland, managing director of Lighting Trades, has been elected, and this will no doubt be as welcome to the many friends he made during his visit to the United States last year as to his colleagues in this country. Dr. G. C. Clayton, a director of the United Alkali Co., succeeded in defeating Mr. Henderson, the well-known labor leader, and there are two or three other manufacturers and directors of technical concerns who will be able to voice the interests of the industry. Max Muspratt, managing director of the United Alkali Co., has just been created a baronet for his past services.

GENERAL NEWS AND NOTES

The Association of British Chemical Manufacturers has just published a new edition of its official directory and classified list of manufactures, which is again printed in six languages, with the notable difference that one of these is now German, to the exclusion of Russian. An amusing feature is the printed list of the officers and council, and it is something of a shock and seems somewhat unnecessary to see Herr Charles Carpenter, Herr E. F. Armstrong, etc., branded with German titles, while in the same list people like Sir William Alexander and Sir John Brunner go scot free. It might have been better to adopt the American habit and give them all the prefix Dr., but needless to say, this does not in any way detract from the usefulness of the publication. The ninth and last volume of the "Technical Records of Explosives Supply" has just been issued by the Ministry of Munitions and deals in a characteristic way with the subject of heat transmission. A memorial tablet to Sir William Ramsay was unveiled at Westminster Abbey last week in the presence of a large and distinguished gathering. Bronze medals struck in honor of this distinguished chemist are now obtainable.

Art and Science of Leather Manufacture—I

First of a Series Outlining the Modern Leather Industry—Kinds and Sources of Hides and Skins — Flaying — Preservation and Cure—Defects—Diseases—Skin Structure and Chemistry

By F. L. Seymour-Jones
Research Scholar, Columbia University

THE tanning industry is unique in that its raw material is a byproduct of agriculture and its finished product is again raw material for the manufacturer of shoes, harness, saddlery, belting, fancy goods and a host of other leather products. No farmer grows an animal for its skin, neither does the value of the skin play any part in the selling price of the animal. Consequently the tanner has as raw material a product variable not only in nature but in the state in which it is turned over to him, according to the care which has been given to it. This position has operated against that standardization which is so characteristic of many branches of American industry. On the one hand, it puts a premium on practical knowledge gained by long experience, a true empirical judgment; on the other, it has resulted in the preservation as trade secrets of processes which the proper application of modern chemical knowledge can often replace cheaply and effectively.

Tanning an Ancient Trade

Tanning cannot yet rightly be classed as a chemical industry. It is one of the most ancient of trades, for the prehistoric hunter certainly learned to dress skins for clothing before he settled down as a planter. But despite early spasmodic efforts at introducing chemistry into the trade—notably by Sir Humphry Davy in 1803—it is only in the last 50 years or so that real progress has been made. Friedrich Knapp, of Germany, in 1858 published his "Die Natur und Wesen der Gerberei und des Leders," dealing with mineral and fat tannages and a theory of tanning. Those interested will find an English translation in the *Journal of the American Leather Chemists' Association*, vol. 16, pp. 158-81 (1921). The late Wilhelm Eitner, in Austria, and Henry Richardson Procter, in England, were the chief among the pioneers in studying tanning processes from a scientific viewpoint. In the last 20 years the number of investigators has multiplied greatly; most countries now have tanning schools and several have research institutes. But there are still many tanneries which do not have a chemist at all. In many others his job is limited to the necessary but uninspiring work of analyzing raw materials (tanning extracts, oils, etc.) and exercising some form of analytical control over the processes.

The reasons for this state of affairs are twofold. Tanners, as a body, are innately conservative, and processes are handed down from father to son for generations, being kept as firm secrets. On the other hand, the problems which beset the leather chemist are among the most recondite of modern science. His raw materials include hides, mixtures of proteins of unknown composition, complicated by their biological origin; vegetable tanning materials, the chemical nature of which is only just beginning to be made clear by the researches of Emil Fischer, Karl Freudenberg and their pupils; mineral tanning agents, notably chromium compounds, perhaps the most unreasonable and complicated of any in inorganic chemistry. The solution to the chemist's problems lies in the application of modern physical and colloidal chemistry, but the chaos existing in the latter subject again hinders progress. In addition he has structural organic chemistry and also enzyme actions to study.

It is only in the last few years that the real fundamentals of the subject are being attacked. The pioneers cleared the ground ably and well, and those suitably qualified are now entering into their inheritance in an almost virgin soil.

There are many definitions both of leather and of tanning. The processes used, or capable of use, are so many and varied that it is impossible to give an entirely satisfactory definition. Broadly, tanning covers the conversion of the readily putrescible hides and skins of animals into a practically imputrescible and durable product known as leather.

The principal raw materials which the tanner has to deal with are hides and skins. The distinction between them is purely one of trade usage, and no hard or fast line can be drawn. The term hide is generally reserved for the larger animals, the ox, cow, heifer, bull, horse, walrus, etc., while the smaller animals provide skins—calf, sheep, goat, pig, seal, etc. Of intermediate size are kips, which strictly speaking are the hides of the small East Indian buffalo.

Sources and Kinds of Hides and Skins

Easily the most important hides are those of the ox or steer. These are obtained not only by local supply in all countries supporting oxen but also by export from cattle-raising countries. The United States ranks high in this respect, and hides from the packing houses have a well-deserved high reputation. Another large source is the Argentine and Uruguay, whence come the *saladeros*. Steer hides, properly flayed, and minus head, horns, etc., range from about 50 lb. to 90 lb. and even more. Their quality depends not only on natural and artificial damages (of which more will be said later) but also on their source. In general cattle from hilly districts furnish better hides than do lowland or plains cattle. Attempts to hasten fattening with oil cake and similar materials tend to produce a more greasy and poorer hide.

The portions of a hide are referred to as bends or butt, bellies, shoulders and cheeks. Except for the first, these terms are self-explanatory. That portion of the hide covering the back and sides of the animal forms the butt, divided into two bends by a line down the backbone. The butt is by far the most valuable portion. The rest is referred to in general as "offal." That side of the hide next the flesh is known as the "flesh," while that of the hair is the "grain."

A steer hide yields a stout, firm butt of close fibrous texture. The bellies are somewhat looser in texture. Younger oxen yield better hides than old ones. Those from beasts used as draught animals are inferior.

Bulls give coarser and more spongy hides, and are usually very thick in the neck and belly, with many wrinkles and folds. Cowhides are flabby, of little elasticity and of poor strength. Heifers yield nice, close-grained hides, which are not as stout or strong as those from the ox.

Horsehides are obtained both from local supply and from South America. They yield a very smooth leather of medium thickness, largely used for boot uppers. Walrus and hippopotamus hides are occasionally tanned, furnishing a very thick leather, chiefly used for burnishing implements and in brake linings.

Kips come from the 1- or 2-year-old cattle of India. They are considerably smaller than oxhides and vary greatly in quality. Prior to 1914 they were exported largely to Great Britain and Germany, either cured or tanned locally. The war, however, caused a great expansion of the Indian tanning industry, and, though it has been badly hit by the slump, a definite permanent advance in tanning more locally is likely to be the result.

Calf and Goat Skins

Calfskins are of variable supply, according to the demand for and the price of veal. In general the bulk is obtained within the country of tannage, and there is no great export and import. They furnish skins of very even, close and fine texture, the female being finer than the male. The finest skins of all are from those animals which have not been weaned. Almost as soon as the calf goes to grass, the extremely fine texture of the milk-fed animal disappears.

In goatskins the United States easily holds pride of place, importing largely from abroad, particularly from India, China, South America, South Africa, the Balkans and the Near East generally. The skin is of a characteristic grain pattern, boldly marked, and is extremely tough and strong. Goatskins furnish the true morocco leather, used for a great variety of purposes. Kidskins are not in great supply. They are of exceedingly fine texture, the same remarks as to sex and feeding applying here as for calfskins. They are dressed largely in France for glove leather, and also come into use for fine grades of shoes. "Glazed kid" is made chiefly from goatskins and is primarily a United States product.

The most important of skins is undoubtedly that of the sheep. Some form of sheep occurs in almost every country throughout the world. But sheep are grown either for mutton (as in New Zealand and the Argentine) or for wool (as in Australia), and it is those countries that are the chief exporters. The quality of the skins varies greatly. Those with fine wool are generally poor, thin and soft. Those grown for mutton are usually fattened with artificial feeding stuffs, and are in consequence exceptionally greasy and fatty. The ideal skin from the tanner's viewpoint is obtained from the mountain sheep; small in size, but of a firm fiber and texture, it yields a very high class of leather. The dewooled skin is technically known as a pelt. The uses of sheepskin are manifold; fancy leathers (including anything from a purse to a vanity bag), bookbinding, slippers, hat linings, cheap shoe uppers, and the imitation of other leathers (morocco, kid and pig).

FIG. 1—REMOVING CATTLE HIDES FROM BELLIES

Lambskins are of an exceedingly fine grain and delicate texture, these qualities rapidly disappearing with growth, especially after the first month. They are used for the finer leathers, notably for glove "kid." Dressed while they still have their short, curly wool, they furnish astrakhan, though this term was originally applied only to slink and pre-natal lamb skins.

Pigskins are of only limited supply, chiefly because in many countries it is customary to sell the skin with the meat, whence it appears on the breakfast table with the bacon as rind. They have a characteristic grain structure, with well-marked hair holes which, in genuine pigskin, also appear on the flesh side. They are used chiefly for saddlery, leggings, bookbinding and bags.

Kangaroo skins, obtained of course from Australia, are of smooth, close texture, and yield a good leather, used much for boot uppers. Sealskins come from the true seal, and not from the fur-bearing animal. They are obtained around Newfoundland, northern Europe and the Cape of Good Hope. The skin is very oily, but yields a very strong leather of compact texture, used for a special type of morocco leather and for japanning or enameling.

Of lesser important skins which come into the market the porpoise, deer, alligator and snake may be mentioned. Shark skin has been introduced in recent years, and other fish skins are sometimes tanned.

Flaying

The process of flaying is outside the tanner's province, but is nevertheless of great importance to him. The old method, still largely used, is with the knife. The danger of cuts, particularly with an unskillful operator, is considerable, and hides may easily be ruined in this manner. It is desirable that no fat should be left adhering to the hide, nor hide tissue to the meat. This requires skill and experience, and even then the best operators use the knife as little as possible, peeling off rather than cutting off the hide. Figs. 1 and 2 give an idea of the methods used by large packing houses.

Many mechanical devices have been suggested, of which two may be mentioned. In one air is pumped in between the skin and the flesh, forcing the skin away from the body, thus rendering its removal an easy matter. In the other the knife is used only for the necessary preliminary slits, the hide being then forced back from the flesh by an automatic hammer.

Of all "take-offs," undoubtedly the best are those from the packing houses in this country and from the large meat plants in South America. Municipal abbatoirs, particularly in large cities, frequently offer premiums for good flaying, which has improved matters somewhat. Hides from private slaughter houses,

FIG. 2—FLAYING HIND LEGS AND BACKS OF CATTLE

local butchers, etc., are often badly flayed. This was particularly the case with East Indian kips until during the war flayers were accorded extra pay for good work.

Once the hide or skin is flayed it is in a readily putrescible condition. Where a tannery is near enough to a local source of supply, fresh hides may pass into work immediately or at most receive a light salting, as is often the case with small country tanneries in England. Generally, however, preservation is necessary both for imported hides and for those collected in such great quantities at the packing houses. Further, the heavy leather tanner in this country usually keeps a reasonably large stock of raw hides on hand to meet emergencies. Thus, at the up-to-date sole leather tannery of the J. H. Ladew Co., Newark, N. J. (Fig. 3), South American hides are stored as shown in Fig. 4. It will be noted that spaces are left between the piles and that wooden frames are inserted about half way up. Sufficient ventilation is thus assured to prevent heating and decomposition. The temperature at the center of the pile can be determined at any time by simply inserting a thermometer through the space formed by the frame.

Salting

The usual method for hides is that of salting. The hides are first washed, to remove adhering dung, dirt and blood, and are piled on horses to drain. They are preferably salted in large cool cellars, maintained at a uniform temperature of about 55 deg. F. The hide is spread on a concrete floor, and salt is liberally applied from a shovel by a man, two shovelfuls being sufficient for a hide. The hides are piled in packs, these being made slightly higher at the edges than in the center, so that the brine will penetrate thoroughly. The salting and piling continue until the pack becomes too high for comfortable work. It is then leveled off and covered over with salt. A pack will be from 15 to 20 ft. long and about half as wide (according to the distance between the pillars on the floor). The pack stands about 2 weeks, which is usually sufficient for the cure.

In "taking up," the hides are stripped from the pack and thrown over a horse (a table with an open top) to shake off the surplus salt. They are then thrown flat on the floor for inspection and classification. Finally they are rolled up, with the shanks (legs) and necks inward, the sides folded over, and a neat roll, 15 to 18 in. wide, made, and tied with rope of the size of clothesline. They are then weighed and are ready for shipment. The salt brushed off is swept up and mixed with the next batch for salting. The salt used should be free from iron, as this gives objectionable stains. Consequently raw rock salt is inadvisable.

Another method of curing largely employed, especially in parts of South America, is dry salting. The hides are washed and then hung up in a cool room to permit excess moisture to evaporate. They are next spread on the floor, flesh side up, and the head, shanks and belly folded in. Salt is spread over the hide, and, as the brine cannot run off, the fibers are thoroughly impregnated. A second salting is frequently given, and the hides are hung up to dry to a slightly rubbery consistency. A final coat of salt is applied prior to export. While this method gives economy of shipping weights, such hides are far more difficult to soak back than the ordinary salted, and the crystallization of the salt may have a weakening effect on the fiber.

An analogous method is applied to East Indian kips. The salt used is an earth, found around Cawnpore, Agra, Delhi, Lucknow and Patna, and consists mainly of sodium sulphate with about 20 per cent sand. This is mixed into a thin paste and applied to the flesh side, the hide being permitted to dry over night. A second coat is given, and even a third and fourth to add weight for export, and the hide finally dried out.

Where salt is not available the method used is straight drying. The hides are hung up in the shade or in sheds, in a well-ventilated spot, until dried out. Where the drying is too slow, through stagnant air, the hide will putrefy and "weak grain" will result. Where it is too rapid, as in the sun, the outside will dry, leaving the inside moist; putrefaction sets in, and, on soaking back, the flesh and grain part company, or whole parts of the hide will dissolve, leaving gaping holes. As it is impossible to detect this damage before soaking, and as soaking back of flint dried hides is often difficult, this is the least satisfactory method of cure.

To withstand insect attacks in store or in transit, some preservative is usually applied to the hides. Sodium arsenite is a useful material for this purpose.

Dewooled sheepskins are frequently imported in the pickled condition. Pickling consists in treating the skins in a bath of salt and sulphuric acid, say 8 per cent and ¾ per cent respectively, and then putting them in a concentrated salt solution to bring down the swelling. One bath alone is frequently used, a concentrated brine bath to which a little acid has been added. Hydrochloric acid may be substituted for the sulphuric, and

FIG. 3—GENERAL VIEW OF MODERN SOLE LEATHER TANNERY

FIG. 4—HIDE STORAGE

organic acids, acetic and formic, have also been used with good effect. A well-pickled skin will keep indefinitely when kept out of water. In depickling some salt must be added to the water or liquor to prevent the acid exerting an undue swelling action as the salt diffuses out of the skin.

Defects of Hides and Skins

Hides and skins are liable to many defects, in addition to faulty flaying, improper drying and putrefaction, already mentioned. Branding of cattle, while a necessary evil, very greatly lowers the value of a hide. It is usual to keep it to one side of the animal only, so that one bend at least may be free. This evil reaches its height in East Africa, where a special brand is applied at each inoculation against the many tropical diseases, and in India, where the cattle are sometimes deliberately branded all over to prevent those castes which eat meat only from animals which have died (and not been slaughtered) from poisoning cattle for the sake of the meat and hides. Barbed wire scratches are also a common defect in close-farmed countries.

The warble fly is a source of considerable damage to cattle, and to a lesser extent to horse hides. It is only very recently that the life cycle of this fly has been discovered after much painstaking research. The fly lays its eggs on the hairs about the animal's hind quarters. From these the larvæ hatch out and burrow into the skin and along the body to the gullet, finally reaching the back, passing through various forms en route. Just beneath the skin the larva bores an air hole, through which it finally emerges on hatching. The loss through these holes to the tanner, and through "blown beef" to the slaughterer, is immense. A kip in the museum of the Leeds University (England) leather department has about 680 warble holes in it, and similar cases are well known to tanners. The British Ministry of Agriculture has a commission studying the question of prevention and cure at present. A final report is expected shortly. The most promising methods are squeezing out the grub by hand (laborious and impossible of general application) and the application of a nicotine-lime wash. By these means it is possible to exterminate the fly in a district in 5 or 6 years, provided the method be thoroughly carried out.

Salt stains arising from the cure are a frequent source of damage to hides. They arise from a variety of causes, chromogenic bacteria, bacterial action through insufficient salting, iron from the salt or from the blood, or from impurities in the salt, where, as on the continent of Europe, denaturants have to be used for commercial salt. The use of a pure salt, or, for a denaturant, of sufficient alkali (5 per cent sodium carbonate) to prevent the development of bacteria, is the best means of avoiding this source of damage.

Sheepskins are liable to many natural ills, of which two are most important to the tanner. Cockle consists of a disturbance of the pelt structure resembling a hard pimple of well-defined appearance, which becomes a deep brownish black in the tan liquors. It appears early in the year, but disappears immediately after shearing. It is largely caused by the intensive fattening of sheep with artificial foodstuffs (oil cake and the like), very common in England. Colt, or dead fat, is another trouble, probably due to the degeneration of the fat cells of the skin, leading to hydrolysis of the fat and crystallization of the fatty acids in the skin. It also is connected with artificial feeding.

The only definite occupational disease of the leather industry is anthrax, arising from infected hides in transit and in soaking. It is particularly prevalent in hides from the East. Various means have been suggested for disinfection, but unfortunately most disinfectants have a tanning action (e.g., formaldehyde, phenols, cresols, etc.) and it is difficult to obtain an efficient one which will not damage the hide. While it is easy to destroy the anthrax bacillus, the spore is highly resistant. A treatment in 1 per cent formic acid and 1 part in 5,000 of mercuric chloride, followed by a brine bath to complete the "wet-salting," has been tested with encouraging results. The use of mustard oil has also been suggested.

Skin Structure

The skins of all mammals have the same general structure, hence a description of one broadly covers all, allowing for particular variations. Some knowledge of this structure is essential for the proper understanding of the working of skins, especially for "splits"—i.e., where the hide or skin has been split horizontally. The skin consists of two principal layers, the epidermis, and the corium or dermis. They are of very different properties and even origin. The fertilized animal ovum rapidly separates into three layers, from the outer of which the epidermis is derived; the corium, together with bones and muscle, develops from the middle layer.

The epidermis is comparatively thin and is removed by the tanner in depilation. It consists of a lower, mucous layer, of living cells, and an upper layer, formed of dead cells, which are gradually worn away. The transition from one layer to the other is not abrupt, but really a series of successive stages of decay. To the epidermis also belong the hairs, sebaceous and sudoriferous glands; though these are deeply imbedded in the corium, they are surrounded by a thin epidermal sheath. The sebaceous glands resemble a bunch of grapes, and serve to lubricate the hair. They are squeezed by the *erector pili* muscle, running from the hair root sheath to the epidermis. This muscle is an involuntary one, and is the cause of "gooseflesh" and of making the hair stand on end. The sudoriferous or sweat glands are connected with the epidermal surface by a spiral duct. Other epidermal structures include horns, nails, claws, etc.

The corium is that major part of the skin which is made into leather. It is composed in the main of a densely interwoven mass of white fibers. Close to the grain surface, and to a lesser degree on the flesh, yel-

low elastic fibers also occur. These serve to bind and support the white fiber bundles, and to draw the skin back to its original shape when stretched. Toward the flesh side groups of fat cells are to be found, and the whole is nourished with fine blood capillaries. The upper layer of the corium is the grain membrane, very thin, and bounded on top by the hyaline surface, which, if damaged, will result in uneven coloring. Below the grain membrane lies the compact fiber-bundle layer of the *pars papillaris*, so called from the projecting papillæ which form the characteristic grain pattern of the skin. Below this layer are the more open-fibered sebaceous and adipose layers (*pars reticularis*), in which the sebaceous glands and hair roots are imbedded, together with fat cells. The corium is connected to the body by a network of connective tissue (*panniculus adiposus*), frequently filled with fat cells. Many animals also possess a thin voluntary muscle (*panniculus carnosus*) just beneath the corium, used for twitching the skin to drive off flies, etc.

Chemical Nature of the Skin

The skin regarded chemically is a very complex body, built up mainly of proteins. Such mineral salts as occur are mainly phosphates and calcium compounds, in addition to those arising from the blood. The proteins belong to the unclassified group—i.e., scleroproteins. The epidermis consists mainly of keratins, the "old keratin" of the outer layer being more resistant to acids and enzymes than the "young keratin" lying next the corium. Keratins are insoluble in water, but are easily hydrolyzed by alkali and sodium sulphide solutions, a property used in unhairing. They are characterized by a comparatively high sulphur content.

The white fibers composing the bulk of the corium are formed of collagen, the parent substance of gelatin. Indeed, it is generally regarded as an anhydride of gelatin. It is insoluble in cold water, but is hydrolyzed in hot water to form gelatin. It swells readily in acids and alkalis, and is eventually hydrolyzed thereby. It is readily dissolved by pepsin, and less readily so by trypsin, unless previously reduced to a powdery state. Freed from keratins and elastin, by liming and bating, the collagen of the hide when ground up forms hide powder used in tanning analysis and experimental work. Far more work has been done on gelatin than collagen; the fibrous structure and insolubility of the latter render it less suitable for experimental work, and results obtained with gelatin usually closely parallel those with collagen. The collagen is the leather-forming substance of the skin, and its combination with tannins, chrome salts, etc., forms leather.

The elastin of the elastic fibers is the most resistant of all the hide proteins to reagents. It is, however, readily hydrolyzed by trypsin, and this property is used in bating. Mucins occur in the cementing substance joining the white collagen fibers together; they appear to be a degradation product of the fibers themselves. The grain membrane is of unknown composition; it is not collagenous, since it does not yield gelatin on boiling. Very little is known of the skin fats, though they appear to be mainly lecithins and cholesterols.

What Is the Meaning of Radium at $70 per Milligram?

Is It "Cutthroat" Competition, Overproduction or Attempt to Put Industry on Stable, Co-operative Basis?

By H. H. Barker

THE public was somewhat surprised when it was announced, a few months ago, by one of the leading producers of radium that the price had been reduced from around $120 to $90 per milligram, but quite astounded when a further reduction to $70 was announced a few weeks ago by still another of the large producers. Who will be next to knock off another $20 to $30? Surprise at this matter is not amazing when we consider that for the past 5 to 10 years there has been an attempt to educate the public to the belief that radium was cheap at the current prices, and that the price must eventually rise. However, there are still those (perhaps they are not apace with the times) who still believe that the time is not far distant when radium will cost twice the sum of $70 per milligram.

In connection with this matter a few facts and some figures may be of interest. Anyone familiar with the radium-bearing ore deposits of the United States is cognizant of the fact that practically all of the ore comes from one section of the country which could be surrounded by a circle 200 miles in radius, and that the condition of mining, quality of ore, etc., are about the same throughout this region except for a few undeveloped deposits of virgin ore. It might therefore be assumed that no one concern has the "drop" on the others when it comes to obtaining the virgin ore at a ridiculously cheap figure.

Production Costs

It has been estimated by quite reliable authorities, who are familiar with the type of mining involved in the production of radium ore, that even under the most favorable conditions for mining a fair group of claims, the cost to produce a ton of 2 per cent uranium ore, containing 5.3 mg. of radium element, will be at least $150. To say the least, this figure is conservative and allows for only a small proportion of development work. As pointed out by George Kunkle,[1] as time goes on and the readily available ore is used up, more and more money will have to be expended in exploration work, with the result that the cost of ore will rise. Mr. Kunkle conservatively estimates the cost of radium in ore delivered to the railroad at $28 per milligram under present conditions.

The cost of processing a ton of ore is somewhat problematical and difficult to estimate unless put on a tonnage basis, where a certain quantity of ore is treated per month, 12 months of the year. However, it is probably safe to estimate that the cost may range from $100 to $150 per ton, depending upon the quantity of ore treated, overhead expense, methods used, cost of chemicals, labor, etc. The cost of recovering the uranium and vanadium is not taken into account here.

Taking the average of the figures given for the cost of processing, plus the cost of the virgin ore, we find that we have invested in the radium recoverable from 1 ton of 2 per cent uranium ore a total of $275. In the event that a recovery of 85 per cent is obtained (which

[1] *Eng. Mining J.-Press*, vol. 114, No. 12, p. 503, Sept. 16, 1922.

is undoubtedly higher than any company now producing can boast of over its entire period of production), the cost per milligram will be approximately $61, while on the basis of 80 per cent recovery the cost will be approximately $65. Add to this the cost of selling, plus the cost of maintaining the service which certain companies have established, and the total cost is easily $75 per milligram.

The average merchant feels that he is entitled to from 20 to 50 per cent profit on the commodities which all of us must of necessity buy. Certainly a radium manufacturer is entitled to a profit comparable to this, and it is questionable whether his margin should not be much greater when we consider what a risky undertaking the production of radium is and what opportunities for losses are involved. However, let us assume that the manufacturer is entitled to a profit of one-third the cost of production. On this basis the minimum price which radium should sell for is $100 per milligram.

In other words, it would seem that concerns which are selling radium produced from American ores at a price much under $100 are losing money and will ultimately face a deficit. A fact that further substantiates the statement that there is no profiteering in radium at $100 is that only one of the large producing concerns has ever paid any dividends, and in its case it is also a well-known fact that its radium has netted it well above $100 per milligram. What industry is able to go on indefinitely without paying dividends? Sooner or later those who have been doing their financing will become impatient and discouraged, unless they realize some returns in the way of real money.

Possible Significance of Cheap Radium

There appear to be four possible solutions to account for $70 radium, which will be briefly presented:

1. This reduction in price may be a means of discouraging competitors and in some instances putting the smaller fellow out of business. It might also serve to discourage new capital which may be contemplating entering the industry. Provided the position of some of our American manufacturers is so strong financially that they can afford to do this, it may be very effective, but it is a question whether they will not impair their own financial condition before they do that of some of their competitors. The fellow who is viewing the situation from the spectators' bench has nothing to lose but his time.

2. This reduction in price may be a bargain sale on radium, used as a means of raising real money on a large inventory of finished product. In the long run this would seem to be rather poor business, as it upsets the market, which, in the handling of a commodity such as this, is apt to slow up buying and create certain obstacles which may be difficult to surmount when the readjustment time comes. Then too, these firms are sacrificing their product at a price below cost of production, and eventually will have neither radium nor money.

3. This reduction in price may be the result of prospective importation of radium. From good authority, it has been ascertained that there was received in Belgium a few months ago 60 tons of 50 per cent uranium ore, from which 6 to 7 grams of radium can be obtained. The extent of the deposits in the Belgian Congo from which this ore was obtained is unknown, but it is quite improbable to conceive of their having a mountain of such ore. It might be well in this connection to call attention to the fact that several tons of very high-grade ore (perhaps not 50 per cent) have been taken from pockets on some American claims, but it did not follow that the entire region was permeated with such ore or even the entire claim from which the high-grade ore was obtained. It is logical to assume that one of these high-grade pockets was struck in the Belgian Congo deposit and that the ore has been pretty well removed. It is possible, of course, that there may be a tonnage of fair ore available, and again there may not be any appreciable quantity of ore of a commercial grade. What the total production of such a find will amount to time only can determine.

4. Have recent advances in X-ray therapy made some producers of radium fear for the stability of their industry? On this point the writer has no definite data, but he feels that this factor has had no material influence in the present slump in the price of radium.

Effect of Slump on Industry

However, let us assume that the 60 tons has been processed and the radium is ready for marketing. It is easy to realize that the cost per milligram will be nominal on such a grade of ore, and a handsome profit can be realized selling for $70 even allowing a $20 commission. It is quite possible that some of our American organizations have the agency for this material and are thus able to put radium on the market at this low figure.[2] Such a price for radium, in small quantities, is not only demoralizing to the other producing concerns but it is also demoralizing to the customer. He immediately assumes an attitude of suspicion, for, as stated before, he has been educated to expect an increase in price, and, contrary to his expectation, comes a decline. It is considered good business never to buy on a declining market, and presumably many persons will look at this situation in such a manner. Equally true, it is considered good business to buy on a rising market provided you get in shortly after the price starts to mount. Perhaps we are just preparing for a rise in price by getting right down to rock bottom as a basis.

When all is said and done, we must come to the conclusion that even in the event that the market for radium is somewhat demoralized at present on account of imported material, we shall eventually have to get back to the consumption of our own product, and with such consumption an advance in price is inevitable.

What is to be the outcome of all this "cutthroat" work in the marketing of radium? Undoubtedly, the survival of the strong—and possibly the fit—who are able to weather the storm and after the "fly-by-night" concerns have passed by will have a legitimate industry whereby they may realize a fair return on their money invested. When such time comes we shall undoubtedly see more co-operation among the producers than there has been in the past, and we shall not have such large variations in the price of radium as quoted on a recent order of fair size. The prices quoted ranged from $77 to $120 per milligram. Some such a co-operative agreement would undoubtedly prove to be of benefit to the large as well as the small producer, and can be most efficient in helping to establish the future of radium both in the professions and as an industry.

Columbia, Mo.

[2] Editor's Note. It has recently been announced by the Radium Company of Colorado that since July last members of the executive and technical staffs of the Radium Company of Colorado have been in Belgium working out details of the new radium enterprise, and that the Radium Company of Colorado, with main offices in Denver, which is to market the Belgian product in America, has formed a joint corporation with the Société Générale du Radium to market radium throughout the world.

A Method for Determining The Rate of Sulphation Of Storage Battery Plates

Experiments Which Have Been Made to Develop a Speedy and Accurate Method for Measuring the Effect of Impurities in Storage Battery Electrolyte—The Fundamental Theory of the Method, and Measurements of the Rate of Sulphation of the Lead Plates in Pure Solutions

By G. W. Vinal and L. M. Ritchie
Bureau of Standards, Washington, D. C.

THIS investigation was undertaken to establish if possible a speedy and accurate method for the measurement of the effect of impurities in storage battery electrolytes. Preliminary experiments in which small cells were "poisoned" by the addition of the substances to be studied showed that accurate and consistent results were difficult to obtain. The capacity of the negative plates is ordinarily greater than that of the positives and the effect of such impurities as affect the negative plate is therefore masked, in part at least, when determinations of the capacity are made. It is difficult also to insulate the small cells so perfectly that leakage current during the periods of standing will not affect the measured capacity. It is often necessary to permit several weeks to elapse in order to determine the loss in capacity resulting from the impurities which are added. Because of the inaccuracies of this method and the time required, it was decided to determine the effect of the impurities in terms of the rate of the reactions taking place at the plates. This may be accurately determined in a short time by successive weighings of the plates immersed in solutions which are maintained at a constant temperature.

In the present paper it is desired to present only the fundamental theory of the method and the results which have been obtained for the rate of sulphation of positive and negative plates in solutions of pure sulphuric acid of various concentrations. According to Dolezalek[1] measurements of the rate of self-discharge of the plates in varying concentrations of the electrolytes have not been made. The method here described affords a simple and accurate means of obtaining this information. The changes taking place at the negative plate are most readily studied by this method, but the interpretation of the results obtained on positive plates presents greater difficulties. The method is not immediately applicable to the study of such impurities as serve as oxygen carriers between the plates of different polarity. In a subsequent paper the effects of impurities will be discussed.

Arrangement of the Apparatus

The general arrangement of the apparatus is shown in Fig. 1. Twenty-four plates were suspended by glass hooks and entirely immersed in the electrolytes, which were contained in six rectangular glass jars, four plates to each jar. These jars were carried on a revolving frame in the thermostat bath which permitted the plates in any jar to be brought to a point directly underneath the left-hand arm of the balance. The balance was mounted on a marble slab over the thermostat tank as shown in the illustration. By this arrangement it was possible to weigh each plate while immersed and without exposing it to the air. The thermostat tank was filled with water to within 1 in. of the top of the jars. The temperature of the water could be controlled by a thermo-regulator at any desired point within the range 20 to 40 deg. C. The variation of the temperature of the water from a fixed point was within 0.01 deg. The water was stirred continuously. Each jar was provided with a wood cover impregnated with paraffine.

The plates selected for the experiments were those made for starting and lighting batteries by two manufacturers. Small sizes of plates were selected to avoid overloading the balance, which was of high quality having a nominal capacity of 200 grams. The plates of maker A were $5\frac{5}{8}$x$4\frac{1}{8}$x$\frac{3}{32}$ in., those of maker B were approximately $5\frac{5}{8}$x$4\frac{3}{4}$x$\frac{3}{32}$ in.

To adapt plates to the conditions of our experiments, the lug was cut off and burned on again in the middle of the top edge in order to balance the plate when suspended in the liquid. Two holes were drilled in the lug. One of these was used for the glass hook which suspended the plate from the balance during weighings and the other for a second glass hook which supported the plates when weighings were not in progress.

Experimental Results

Weighings of the plates were made daily and the results computed as the increase of weight per hour. Three sets of weighings extending over a period of 48

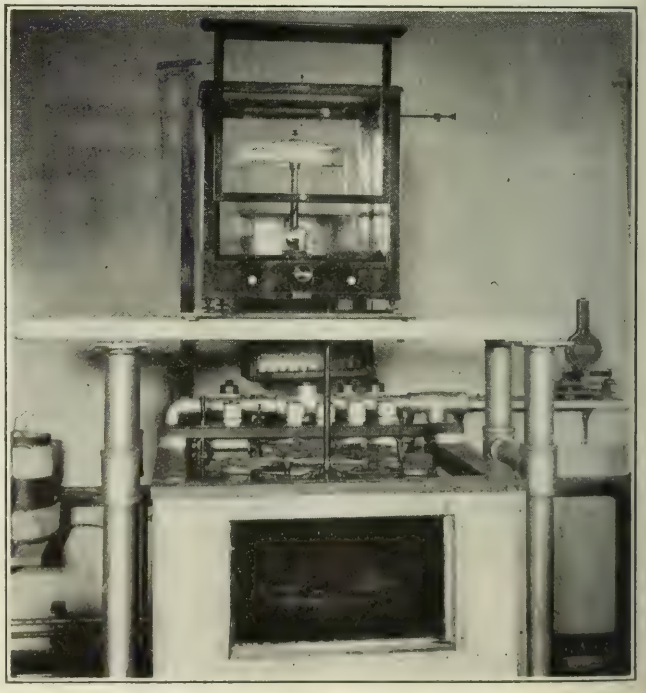

FIG. 1—APPARATUS FOR DETERMINING RATE OF SULPHATION OF STORAGE BATTERY PLATES

Published by permission of the Director of the Bureau of Standards.

[1] "Theory of the Lead Accumulator," p. 139.

hours were sufficient to give two determinations of the rate of change in weight of the plates. These two determinations in nearly all cases were in good agreement. Four weighings at 25 deg. C. were made, giving three determinations of the change in weight. The mean of these is given in the table below. Since the weighings were made in the electrolyte, a buoyancy correction was necessary. This correction has been calculated on the assumption that the materials have the following densities:

Lead	11.3
Lead sulphate	6.3
Lead peroxide A plates	8.7
Lead peroxide B plates	8.8

Since the values for the density of lead peroxide found in the literature differ widely, determinations of the density of the active materials of the positive plates in the fully charged condition have been made by Mr. Peffer at the Bureau of Standards with the results given above. Analysis of the active materials by Mr. Altrup shows 97 per cent lead peroxide in the positives of each manufacturer, 97 per cent lead in the negatives of manufacturer A, and 91.5 per cent lead in the negatives of manufacturer B. The expanders in the negatives were carbon in each case. The buoyancy corrections are applied to a small difference of two weighings, and hence a slight error in the density of either the solutions or the active materials produces a negligible error in the final result.

The densities of the solutions were determined directly by the use of calibrated hydrometers.

The chemical reactions during discharge at the plates are generally assumed to be:

$$Pb + SO_4 = PbSO_4 \qquad \text{Negative plate}$$
$$PbO_2 + H_2 + H_2SO_4 = PbSO_4 + 2H_2O \qquad \text{Positive plate}$$

Since the molecular weight of lead is 207.20 and of lead sulphate 303.26, the gain in weight during the transformation of 1 mol of lead to lead sulphate is 96.06 grams and the relative gain in weight (96.06 ÷ 207.20) times the weight of lead acted upon. There is of course a large amount of lead which does not take part in the reaction and decreases the sensibility of the weighings, but in spite of this fact and the heavy damping resulting from the viscosity of the electrolytes the balance was sufficiently sensitive to permit an accuracy of a few tenths of a milligram to be obtained.

From the rate of change in weight of the plates the equivalent loss in ampere-hour capacity can be computed. The valence is 2 and hence a gain in weight of the negative plate of 96.06 grams is equivalent to 2 × 96,500 coulombs. From this the change in weight is computed to be 1.79 grams per ampere-hour.

Both chemical and electrochemical reactions are possible at the negative plate, but the former are probably predominant over the latter during self-discharge. This is indicated by the results for the A plates in 1.150 and and 1.400 acid. The gain in weight per hour in the stronger acid is twenty-three times that in the more dilute. The change in potential of a lead plate as the concentration of the electrolyte is changed from 1.150 to 1.400 sp.gr. is less than 0.1 volt, according to the measurements of Gladstone and Hibbert.[2]

The resistivity of the more concentrated electrolyte is higher than for the 1.150 sp.gr. electrolyte. On the basis of Ohm's law, therefore, this marked increase in the extent of the reaction cannot be readily accounted for as an electrochemical reaction.

[2] *J. Inst. Elec. Eng.* (British), vol. 21, p. 430 (1892).

TABLE I—GAIN IN WEIGHT, GRAMS PER ECUR, OF NEGATIVE PLATES IN SOLUTIONS AT 25 DEG. C., SATURATED AND UNSATURATED WITH LEAD SULPHATE.

Sp. Gr. $\frac{25° C.}{25° C.}$	Gain in Weight for Plates of Manufacturer A, Sat. Sol.	Manufacturer A, Unsat. Sol.	Manufacturer B, Sat. Sol.	Manufacturer B, Unsat. Sol.
1.150	0.0022	0.0031	0.0048	0.0058
1.200	0.0026	0.0071	0.0118	0.0120
1.250	0.0036	0.0098	0.0178	0.0290
1.300	0.0060	0.0115	0.0283	0.0394
1.350	0.0151	0.0270	0.0385	0.0558
1.400	0.0460	0.0480	0.0906	0.0960

The measurements on the negative plates at 25 deg. C. are given in Table I. Each figure is the mean of six observations (three measurements on each of two plates). Buoyancy corrections have been made.

These results show that the rate of sulphation is decreased appreciably in the saturated solutions of concentrations corresponding to those ordinarily used in storage batteries. The solutions were saturated with chemically pure lead sulphate when hot and were permitted to cool before the plates were immersed. The electrolyte in a lead storage battery is ordinarily saturated with lead sulphate, although the electrolyte is initially a solution of pure sulphuric acid. In the unsaturated experiments the ratio of the mass of acid to the mass of the plates was so large that saturation could not occur in as short a time as is ordinarily the case. Each jar contained 4.5 liters of solution and four negative plates.

The question has been asked, Why it is injurious to permit a discharged cell with low gravity of electrolyte to stand when the results of this paper show that the rate of sulphation is less in the solutions of low gravities? The answer is that the low gravity of electrolyte in the discharged cell is merely incidental and the state of charge of the plates is the controlling factor. The plates for these experiments were initially fully charged.

The rate of sulphation decreased as time progressed. This is especially noticeable in the case of the plates of manufacturer B in the unsaturated solutions of higher concentration, as is shown in Table II.

TABLE II—DECREASE IN RATE OF SULPHATION WITH TIME, NEGATIVE PLATES IN UNSATURATED SOLUTION.
(Measurements on Plates of Manufacturer B.)

Date	Gain in Weight, Grams Per Hour, for Each of Six Concentrations: 1.150	1.200	1.250	1.300	1.350	1.400
Feb. 19	0.0059	0.0132	0.0304	0.0416	0.0574	0.0976
Feb. 20	0.0053	0.0110	0.0289	0.0414	0.0560	0.0964
Feb. 21	0.0061	0.0121	0.0275	0.0352	0.0535	0.0942
Feb. 22	0.0050	0.0118	0.0260	0.0369	0.0484	0.0818
Feb. 25	0.0052	0.0110	0.0247	0.0359	0.0498	0.0819
Feb. 27	0.0053	0.0113	0.0236	0.0332	0.0470	0.0769

It can easily be computed that the capacity of the plates would be exhausted in a relatively short time if the initial rate of sulphation were to continue indefinitely. The decrease in the rate of sulphation is probably to be attributed to the protection which the lead sulphate affords to the underlying active material and also the increasing amount of lead sulphate present in the solutions which were initially unsaturated. The effect of the presence of lead sulphate in decreasing the rate of sulphation of the plates has been shown in Table I, but the effect of saturating the solution in holding the rate of sulphation constant for a few days during which measurements of the effect of impurities can be made is of fundamental importance in establishing the validity of this method. This is made clear in Table III, in which comparative results for the plates of manufac-

turer A are given for a period of 3 days for both the saturated and unsaturated solutions. The results with the minus signs express the decrease in rate of sulphation during this time. Inconsistent results are to be observed for the solutions of 1.150 and 1.200 sp.gr., but this is not surprising, since these solutions are in the region of the minimum solubility for lead sulphate according to the curve given by Dolezalek.[3] In this region there can be but little distinction drawn between saturated and unsaturated solutions. The measurements made on the plates of manufacturer B were not as consistent as those for manufacturer A because of a tendency for the active material to scale off, which produced an error in the results.

TABLE III—EFFECT OF SATURATING THE ELECTROLYTE WITH LEAD SULPHATE ON THE CONSTANCY OF THE RATE OF SULPHATION OVER A PERIOD OF 3 DAYS

(The minus signs indicate a decrease in the rate and plus signs an increase. Plates of manufacturer A)

	Change in the Rate of Sulphation, Grams Per Hour, in Solution at 25 Deg. C.					
Solution	1.150	1.200	1.250	1.300	1.350	1.400
Unsaturated....	+0.0017	+0.0013	—0.0031	—0.0045	—0.0029	—0.0037
Saturated.....	0.0000	+0.0005	0.0000	0.0000	—0.0009	—0.0014

The effect of temperature on the rate of sulphation is important. In Table IV are given the measurements made on the negative plates of both manufacturers when the solutions were maintained at constant temperatures of 22, 25 and 30 deg. C. The increase in the rate of sulphation from 22 to 25 deg. is proportionately greater than from 25 to 30 deg.

TABLE IV—EFFECT OF TEMPERATURE ON THE RATE OF SULPHATION OF NEGATIVE PLATES

Sp.Gr. 25° C. / 25° C.	Gain in Weight, Grams per Hour, Saturated Solutions for Plates of — Manufacturer B —			— Manufacturer A —		
	22°	25°	30°	22°	25°	30°
1.150.....	0.0031	0.0048	0.0056	0.0012	0.0022	0.0022
1.200.....	0.0073	0.0118	0.0118	0.0016	0.0026	0.0027
1.250.....	0.0111	0.0178	0.0196	0.0028	0.0036	0.0051
1.300.....	0.0183	0.0283	0.0325	0.0046	0.0060	0.0082
1.350.....	0.0270	0.385	0.0420	0.0122	0.0151	0.0198
1.400.....	0.0614	0.0906	0.1027	0.0350	0.0460	0.0544

Local action at the positive plate is essentially electrochemical, resulting from the difference in potential between the oxide and the lead-antimony alloy of the grid. Metallic impurities are not precipitated by the oxide, and Dolezalek and Finckh[4] have stated that no solubility of the peroxide in solutions of the specific gravities ordinarily used in storage batteries can be detected. The reaction at the positive plate in these experiments is therefore to be regarded as the general expression for the discharge of a cell, with the qualification that the negative electrode may be lead or lead-antimony alloy depending on the construction of the plate.

$$PbO_2 + Pb + 2H_2SO_4 = 2PbSO_4 + 2H_2O$$

The lead sulphate formed appears on both the peroxide and the grid.

The gain in weight of the positive plates is not as simply related to the total amount of sulphate formed as in the case of the negatives. The sulphate which forms on the grid or the underlying lead is equal to 96.06 grams for 2 × 96,500 coulombs, but the change in weight of the positive plates because of the formation of sulphate on the peroxide is 64.06 grams for the same quantity of electricity. The difference is accounted for by the formation of 2 mols of water at the peroxide.

[3] "Theory of the Lead Accumulator," p. 145.
[4] *Z. anorg. Chem.*, vol. 51, p. 320 (1906).

TABLE V—GAIN IN WEIGHT, GRAMS PER HOUR, OF POSITIVE PLATES IN SOLUTIONS AT 25 DEG. C. SATURATED AND UNSATURATED WITH LEAD SULPHATE

Sp.Gr. 25° C. / 25° C.	Plates of Manufacturer A		Plates of Manufacturer B	
	Saturated Solution	Unsaturated Solution	Saturated Solution	Unsaturated Solution
1.150.....	0.0128	0.0111	0.0077	0.0138
1.200.....	0.0121	0.0096	0.0077	0.0090
1.250.....	0.0069	0.0060	0.0047	0.0051
1.300.....	0.0053	0.0022	0.0050	0.0061
1.350.....	0.0050	0.0019	0.0048	0.0062
1.400.....	0.0047	0.0031	0.0049	0.0088

This means that 160.12 grams of sulphate would be formed on the positive plate if the quantity of electricity flowing were 2 × 96,500 coulombs. The ampere-hour equivalent for the gain in weight resulting from local action, is, therefore, 2.99 grams for each ampere-hour. The experimental results for the positive plates in solutions of varying concentration at 25 deg. C. are given in Table V for solutions saturated and unsaturated with lead sulphate.

It will be observed from the results given in Table V that the gain in weight of the positive plates decreases as the concentration of the solution increases. This suggests that the plates contained some soluble constituent, the solubility of which increased as the concentration increased, but the data which are available on the solubility of lead peroxide and lead oxide fail to offer an explanation. In the solutions which were saturated the gain in weight of the plates was more for manufacturer A but less for manufacturer B than in the unsaturated solutions. The difference in behavior may be attributed to the different methods used in preparing the paste for these plates, but no exact explanation can be given now.

Petroleum Laboratory List Being Compiled

The Bureau of Mines is revising its list of commercial laboratories to which correspondents are referred when they wish to have chemical analyses made. This is necessary because the policy of the Bureau of Mines does not permit making analyses for private individuals unless such analytical work forms a part of a larger project which is being carried out by the bureau in the public interest. Due to an unforeseen delay the formal questionnaires which were to be sent out in connection with the revision of this list have been held up. They are now being forwarded to the various laboratories, however, and a prompt response is hoped for. Laboratories which are not on the present list are invited to communicate with the Bureau of Mines relative to their ability to carry out the various tests on petroleum products. The bureau reserves the right to limit the list to laboratories that appear to be qualified to do the work.

Gummy Substances in Gasoline

A study of various methods of evaporation and oxidation of cracked gasolines made by the Bureau of Mines leads to the conclusion that gummy and resinous deposits are caused by oxidation and have no direct relation to unsaturation as determined by solubility in sulphuric acid. In the investigation made by the bureau a new and convenient method was developed for determining "gum" in gasoline. The study of gums and their formation leads to the conclusion that they are polymerized aldehydes, which probably are formed by the oxidation of olefins, etc. Storage tests confirm the above conclusions. Details of the investigation made by the Bureau of Mines are given in Serial 2394, "Gum-Forming Constituents in Gasoline," just issued.

The Protective Action of Copper in Case Carburizing

By James C. McCullough (Associate Professor) and H. A. Holden Pray
Severance Laboratory of Oberlin College, Oberlin, Ohio

ONE of the common methods of preventing action on certain parts of a piece of steel that is being carburized by the cementation process is to cover these parts with a plating of copper. Even though this is common practice, it fails at times in a way that is not understood. Illustrating this, we quote a few sentences from a discussion following a paper on "Case Carburizing" by C. G. McFarland, as published in the *Transactions* of the American Society for Steel Treating, vol. 1, page 305:

Mr. Stenger: "I would like to ask if you can give us an explanation of just why copper plating prevents carburization."

Mr. McFarland: "I cannot."

Chairman: "Maybe somebody here would like to ask the question why it does not at times."

The literature records some work along this line by Giolitti, Habec, Guillet and Bernard, Zimmerli, and others and is contradictory to a degree. We have been studying the matter at some length, and in this communication, which is in the nature of a progress report, we give the ideas we have so far acquired. If any readers have had experiences which bear upon the problem we should very much appreciate hearing from them.

Good Plates Easily Made on Good Steel

Of course our first assumption was that the commonly accepted theory of carburization is correct and that CO gas is the active carburizing agent. It also seemed probable from published data that CO does not diffuse through copper to any appreciable degree even at 950 or 1,000 deg. C. We assumed that this failure of the copper protection in certain cases was due to holes in the plating and we tried to prove this assumption.

None of our copper platings on clean, uniform steel failed to protect unless we scratched through the copper. In some cases the copper seemed to diffuse over the scratches or file marks and the sample emerged from the furnace without any sign of carburization. This seems to have been noted by others but not explained. We do not attempt to explain it.

Since all of our first platings from a cyanide bath gave adequate protection, we began to look for some that would not protect even when considerable care was used in plating. A low-carbon steel with slag and ghost lines gave this erratic behavior, and we consequently confined our attention to it in an effort to show at least one reason why copper fails to protect.

Imperfect Results on Low-Grade Metal

The latter material was of low carbon content and in the form of round rods or pieces cut from steel bar ¼ in. thick and 2 in. wide. These pieces were cleaned in hydrochloric acid containing 1 per cent by volume of 40 per cent formaldehyde solution (Holmes patent) and then plated over part of their length in a copper cyanide bath of the following composition: water 10 qt., sodium carbonate crystals 8.5 oz., sodium hydrogen sulphite crystals 7 oz., copper carbonate 7 oz., and potassium cyanide (98 per cent) 8.5 oz. The pieces were then carburized by packing in a sheet-iron box 3x4x6 in., the mixture being 3 parts wood charcoal and 2 parts barium carbonate. The temperature, measured at the center of the box, was held at 1,000 deg. C. for 75 minutes and then permitted to drop with the electric furnace.

Cross-sections of these rods were then examined under the microscope to determine the degree of carburization and the condition of the copper plating. Great care was necessary to prepare these sections without damage to the copper. The method finally chosen was to mount the sample in a type metal composed of lead 8 parts, antimony 2 parts and tin 1 part. Standard pipe caps for ¼-in. gas pipe make convenient cups for this mounting. A harder alloy than type metal would be desirable, but they have higher melting points and dissolve part of the copper. There was a marked tendency for the copper to tear loose from the iron and be carried out into the alloy during the grinding of the sample and even the edge of the iron seemed to flatten out into the type metal mounting. Successful grinding was obtained only by coating the carborundum papers with paraffine, avoiding much pressure during polishing and holding the sample in one position during the entire process instead of changing direction with each change of paper. By this method the one edge of the iron rod where the direction of motion was from type metal to iron could be successfully examined. A new grinding was necessary for each edge examined.

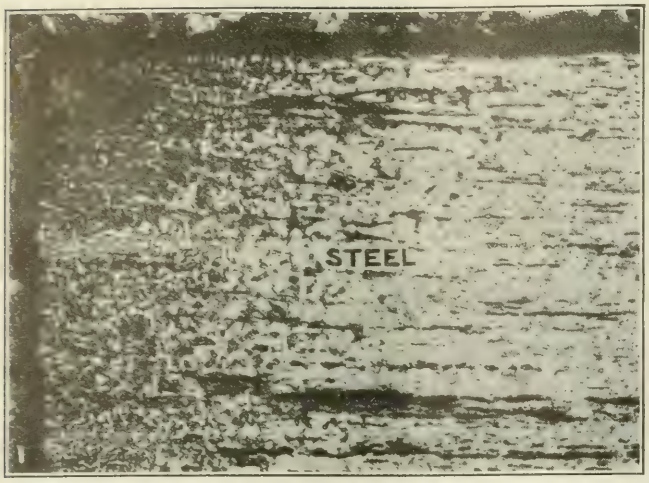
Microscopic examination of such samples was very satisfactory even with the highest power oil-immersion lens, the red color of the copper being very apparent. Photomicrographs were also prepared (some of which are reproduced), but with considerable difficulty. The type metal always ground away to a lower level than the iron and copper, making a sloping junction that was very hard to adjust for clear focusing over much of the field at one time. Photographs were all made on Wratten M plates using Wratten light filters. With the blue (C) filter copper shows in the print as black, while with the red (A) filter the copper prints white and may be distinguished from slag or structure lines in the steel.

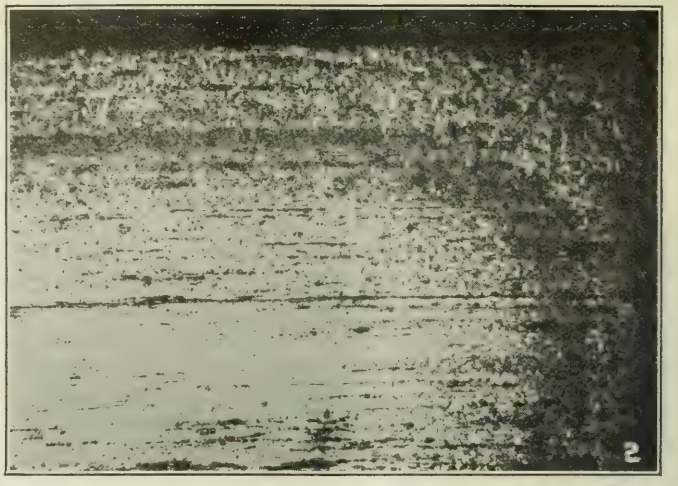
Copper 0.004 mm. Thick Protects Iron

Without exception the samples examined showed no carburization under copper plating, except when there were holes in the copper. Carburization was always in proportion to the number of such holes.

Copper plates perfectly from a cyanide bath on to clean, pure iron or steel providing a low current density is used. We got complete protection with a plating of 0.004 mm. thick deposited at a current density of 0.08 amp. per square decimeter, while a plating 0.006 mm. thick deposited at the rate of 0.6 amp. afforded very little protection and showed many holes. Copper will not deposit on spots of slag or oxide that come to the surface of the iron. Breaks in the copper and consequent carburization always seemed to accompany such structural marks in the steel unless the copper deposit was made very thick.

Figs. 1 and 2 show the conditions at corners at opposite ends of the same sample of low-grade steel bar. One end had been copperplated, the other was bare and clean. After carburization, the clean end (Fig. 2) was seen to be carburized about the same depth inward from the sides and from the ends. This indicates that penetration was no deeper one way than the other, even though the slag lines might have afforded open channels for the gas. We do not believe that CO followed these slag lines to any marked degree, but we are sure that





FIGS. 1 AND 2—CORNERS ON OPPOSITE ENDS OF SAME BAR.
ETCHED WITH 5 PER CENT HNO_3, 95 PER CENT ALCOHOL
Fig. 1—Copper plated end. × 50. Fig. 2—Bare end. × 25.

these slag lines cause holes in the copper plate through which the gas does enter and diffuse into the steel in all directions. This is plainly shown in Fig. 1.

Fig. 1 has a copper plate 0.004 mm. thick (too thin to show at this magnification). Owing to the difficulties in polishing and photographing, the edge of the sample is marked by a black streak, beyond which appear the large crystals of the white-metal mounting. The plating across the "fiber" was quite defective, while it was much more perfect around the sides. Consequently gas penetration was from the ends only. Much of the pearlite in the carburized zones has been divorced, and fairly large masses of carbide may be seen. This occurrence is to be expected in such impure steel, as shown by McQuaid and Ehn in several recent papers.[1] This structure, and breaks in the copper plate, are shown more clearly at higher magnification in Fig. 3. It shows the edge, normal to slag lines, of the same piece of steel photographed in Fig. 1.

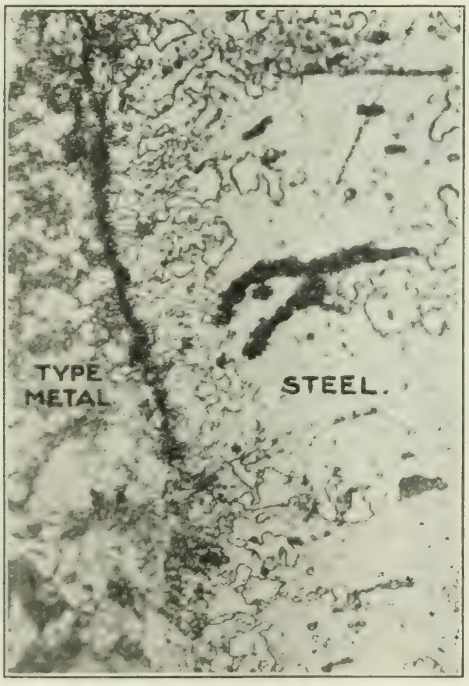


FIG. 3—SAME AS FIG. 1. × 500
Etched with 5 per cent HNO_3, 95 per cent alcohol. Blue filter. A portion of the edge normal to slag lines shows breaks in copper plate and divorced cementite beneath.

Conclusion

Our work strongly supports the following view of the theory of case carburizing and its prevention by plating with copper. It shows the cause of failure in at least some cases and points to a reliable remedy. When soft iron is heated in a charcoal pack, the carbon monoxide gas penetrates into the iron and gives up some of its carbon to the iron to effect the desired carburization. Carbon monoxide gas does not dissolve easily in copper and hence cannot pass through it unless there are cracks or holes in the copper. A thin copper plating over iron should, therefore, prevent carburization unless there are flaws in the copper. We found such flaws in every plating examined that had failed to prevent carburization and we found no breaks in the effective platings.

Treatment of Oil Field Emulsions

D. B. Dow, chemical engineer of the petroleum experiment station of the Bureau of Mines at Bartlesville, Okla., who is making a study of oil field emulsions, recently interviewed a number of operators at Tulsa, Okla., and obtained information on methods of dehydration that are being used by different companies. It was found that most companies are using chemicals for treating oil field emulsions, although in a number of fields the centrifugal process is in rather general use. An extended series of laboratory tests has been made to determine the effects of large amounts of water when produced with the oil. It was found that with 10 per cent oil and 90 per cent water, only a small percentage of B.S. was formed and that about 98 per cent of the water separates on standing. By decreasing the amount of water and increasing the amount of oil, the percentage of B.S. increases and the amount of free water decreases. The laboratory experiments coincide with the information that has been obtained from field men to the effect that in a well producing excessive amounts of water there is less trouble from emulsions than in one that produces a comparatively small amount of water. Additional laboratory tests will be made to determine the effect of finely divided material on the formation of oil field emulsions.

The Donnan Program of Investigation for the Chilean Nitrate Industry

The Present Method of Caliche Treatment Is Outlined and a Critical Examination Is Made of a Recent Suggestion That the Operation of the Shanks Process Should Be the Object of Intensive Scientific Research

By A. W. Allen
Assistant Editor, *Engineering and Mining Journal-Press*

Between December, 1918, and July, 1919, Dr. F. G. Donnan made an extensive investigation on methods of treatment in vogue and results being obtained at a number of nitrate oficinas[1] in Chile. The ultimate sequel to the visit was the publication of an elaborate report,[2] issued by the Chilean Nitrate Committee in London.

Dr. Donnan, who is professor of general chemistry at the University College of the University of London, is well known as one of the leading authorities on many important phases of chemistry. His researches, apart from a brilliance that places him among the front rank of present-day scientists, indicate an originality above the normal. His writings are usually constructive and helpful. He has been an outstanding figure among those who are attempting to solve the many problems connected with colloidity and adsorption; in 1910 he propounded what is now known as the Donnan theory of membrane equilibria, support and elaboration of which is to be found in Dr. Jacques Loeb's recently published monograph on "Proteins and the Theory of Colloidal Behavior."

Dr. Donnan writes fearlessly of conditions on the pampa. The most striking fact revealed by the inspection was the "great dearth of exact quantitative data" and the absence of results of "detailed scientific investigations. The time has come," it is averred, "when these defects must be remedied as rapidly as possible." Investigation work is recommended as the panacea, the report under review being concerned mainly with its organization, direction and control.

In a preliminary section the distinguished chemist deals with the general economic conditions affecting the Chilean industry, discusses the possible competition of synthetic products and emphasizes the fact that "no great industry can progress without keeping a vigilant watch on the progress and development of its competitors." Discussing process control, Dr. Donnan draws attention to the deplorable conditions observable on the pampa. Like many others who have gone before, he found that "no proper means of determining the essential data existed, and such as were determined and reported were often either erroneous or falsified."

Causes Behind Deplorable Conditions Existing on the Pampa

Among the causes of the present state of affairs are mentioned (1) inadequate technical staffs; (2) want of close technical control of the processes of manufacture; (3) the tendency to be satisfied with present profits, regardless of the technical inefficiency of the processes and the wasting of material; (4) the control of the industry by men of business, men unpossessed of any chemical or engineering knowledge. "A clean cut must be made with the methods of the past . . . The highest possible premium must be placed on accuracy and moral and intellectual honesty . . . Only really well-trained men must be appointed—men who have already demonstrated their capacity for technical and scientific investigation."

Verily a "clean cut" will be needed to separate the industry from those who have hitherto had control of technical operations—who have derided the efforts of independent engineers to obtain recognition of fundamental principles—who have systematically discredited scientific fact by the contention that all that could be tried has been tried, "back in the '70s or thereabout" —who discourage initiative by camouflaging the results of inefficient operation so that they appear presentable—who are helping to squander Chile's resources by a determination to ignore the wastage caused by the selective mining of the highest grade of caliche. Dr. Donnan's suggestions as to the need for "moral and intellectual honesty" are especially applicable. If the "clean cut" proposed be made it will mean the elimination of much that is reprehensible in the operation of the industry.

The technical side of Dr. Donnan's report is confined almost entirely to a consideration of the results—actual, possible or problematical—of continuing the present method of operation known as the Shanks process. He maintains that "we must thoroughly control and understand the existing process before we attempt to improve it." The personnel of the proposed research department

[1] Glossary: **Agua feble**—solution obtained by refrigeration of **agua vieja**, which is the mother liquor remaining after the fractional crystallization of high-density nitrate solution to atmospheric temperature; **batea**—crystallization vat; **borra**—sludge found underneath punched-plate support in vat, also in solution and clarifying tanks, also used (incorrectly) to refer to slime in caliche; **cachucho**—boiling tank in Shanks plant; **caldillo**—any liquor with more nitrate than mother liquor and less than **caldo**, which is of the highest density and temperature; **caliche**—nitrate-bearing material containing, in addition to nitrates, soluble impurities in a number of forms and in varying proportions; **chullador**—an open, flat-bottomed vat used to settle the slime and salt in the solution before crystallization; **cancha**—place where nitrate is dried and sacked; **costra**—material of low nitrate content usually found near caliche; **crinolina**—perforated-plate false bottom in treatment vat on which charge of caliche rests; **maquina**—nitrate plant; **oficina**—nitrate property equipped with plant; **relave**—weak nitrate liquor; **ripio**—residue, usually only referring to that portion that comes from above the punched-plate support in the treatment vat; **salitre**—commercial nitrate.

CACHUCHOS IN SHANKS MAQUINA

is to consist of four research chemists, one research physicist, one geologist, one mineralogist, four analytical chemists, one mechanical engineer, one chemical engineer, one mining and metallurgical engineer, two draughtsmen, et al. The technical staff will be chosen, other than in exceptional cases, from among those who have attained "the D.Sc. or Ph.D. standard of the best European and American universities." An ambitious program of work is proposed, involving heavy expense. The candidates should preferably be between 25 and 35, and an "adequate pension scheme" is recommended. The task of finding out what is wrong with the Shanks process is to be tackled in no hasty, commercial spirit.

So little has been published about the Shanks process that it will not be out of place to preface my comments on Dr. Donnan's conclusions by a brief description of its fundamental features. The caliche (nitrate-bearing material), after hand sorting, is reduced in swing-jaw rock breakers to about 3 in. The wearing plates of these abrade at a maximum in the center; and many or few large lumps, according to the condition of the plates, escape proper reduction. The crushed material then goes by conveyor or gable car to the vats, which are rectangular and of iron, six generally forming a nest; each is equipped with steam coils. A perforated-plate support with ⅜-in. holes is fixed a few inches above the bottom of the vat. The caliche is tipped into the upper section and usually segregates into coarse and fine, the steam pipes, acting as a grizzly, aiding the classification that occurs. An even distribution of the material in the vats is looked upon as entirely unnecessary. Large dividends have been paid for years by companies whose technical staffs have followed the original plan.

Operation of the Shanks Process

The arrangement of piping to, from and around a typical cachucho (boiling tank) is shown in the accompanying line drawing. Provision is made for the passage of solution from vat to vat; but as all of these are on the same level, no upward or downward percolation is possible. For the most part the solution passes from underneath the perforated-plate support into the side of the adjoining vat. Enrichment of the solution is achieved by submerging the caliche with liquor from a nearby charge, followed by boiling or high-temperature maintenance. During this phase of operations the liquor becomes thoroughly contaminated with slime; when a high density is reached it is laundered to a settler, where dung or flour is added to assist sedimentation. The clear liquor is then decanted and sent to crystallizing vats, the slimy dregs from the settler going to waste. Owing to the ease with which the nitrate content of the solution can be augmented by evaporative concentration in the cachuchos there is no difficulty in obtaining a high-grade crystal after ordinary cooling to atmospheric temperature. Broadly speaking, the industry is confronted with no problem of a chemical nature directly connected with the manufacture of a high-grade nitrate product from caliche.

After an imperfect displacement treatment in the cachucho, the material is finally washed with water and discharged. The mud that collects underneath the crinolina, or punched-plate support, shares the same fate as that which is discharged from the clarifying vats: it is treated as waste.

Such are the essentials of the Shanks treatment. Various modifications have been proposed or put into practice. Fine grinding has been attempted; but the boiling or high-temperature maintenance in the vat involved the freeing of too much slime. In some oficinas the sludge from below the perforated plates has been removed from a discharging vat and placed on top of one undergoing treatment, with results not difficult to imagine. At some plants an attempt has been made to treat this mud by decantation or filtration, but unsuccessfully. In a few cases the fine constituents of the dry charge have been isolated and treated separately, but the scanty data available have shown that the problem has been only partly solved.

Large Losses on the Pampa Due to Neglect of Fundamental Principles

I do not find myself in agreement with Dr. Donnan's general program. The Shanks process, he admits, has been a miserable failure, as judged by present-day requirements. "We may assume," he says, "that 40 per cent of the nitrate contained in the material arriving at the works is at present lost." This confirms my own opinion that, "although optimistic figures have been given at various oficinas as to the amount of nitrate extracted, it is improbable that the actual recovery in crystal form and ready for shipment exceeded, on the average, 55 per cent of the nitrate originally in the caliche; and it is certain that in very many cases the amount was considerably below this estimate."[3]

Scientific workers are paid little enough, but there is another type of investigator who often gets nothing for his labor. I refer to the person who thinks several times before he acts. A little analytical and constructive thought on the problems of the pampa will do more to bring prosperity back to the industry than will the expenditure of vast sums of money to determine the precise physicochemical happenings in a Shanks maquina. The failure to improve results has been due to a neglect to appreciate the fundamentals of any process employed for the removal of a soluble salt from an insoluble gangue. The technical men in control of the industry apparently refuse to realize the importance of simple and fundamental facts.

Inefficient Extraction in Shanks Process

Dr. Donnan remarks that "Providence has so arranged that in the cycle of the Shanks maquina the unwanted constituents are usually purged with the final boil of the caldo" (liquor of highest density and temperature). But Providence is equally kind to those who have no faith in the Shanks scheme as applied to the extraction of nitrate from caliche, for any solubility curve will show that boiling temperature is not necessary for the selective absorption of nitrate and the release of salt and other impurities. This leads to one of the fundamental weaknesses of the prevailing method of treatment: the evaporation of water from solution in contact with the caliche. "Such concentration," Dr. Donnan remarks, "works against the leaching, and for this reason alone the evaporation, if it be necessary, should be conducted after and not during the leaching." This confirms my own conclusion that "the inefficiency of nitrate recovery—the lengthy time of treatment to obtain even moderately low ripios [leaching-vat residues]—is due largely to the enrichment of the charge by the evaporative concentration of high-grade

[3] "Recovery of Nitrate From Chilean Caliche." Charles Griffin & Co., Ltd., London.

solution and by the addition of caldillo [weak nitrate liquor] and aqua vieja [mother liquor]. These high-grade nitrate solutions have low dissolving powers. Caldo is formed mainly by evaporative concentration, and not by the abstraction of nitrate from the caliche; and this involves the augmenting of the nitrate in the cachucho, resulting in a proportionately high ripio. The boiling or high-temperature maintenance disturbs the equilibrium of the charge, causing the borra [sludge] to circulate with the solution and finally to find its way underneath the crinolina and thence to the surface of other charges or to the relave [weak nitrate liquor] tanks."[4]

The Borra Bogey an Illegitimate Excuse for Poor Yield

In reading Dr. Donnan's report one is constantly reminded of the fact that he has been duly impressed by the borra bogey. When the rotos, or workmen, of the Chilean pampa become fractious at the high cost of beans and carry their grievances to Santiago, the government counters their complaints with a scare: "Peru is about to attack us." "Viva Chile!" they all shout, and prepare to defend their beloved country with the last drop of their Araucanian blood. And the price of beans is forgotten. Similarly, on the Chilean pampa, an inquiry as to the reason for the pitiable results usually obtained by the Shanks process invariably elicits a tale of woe about borra. This bogey should be laid reverently to rest, for it has worked hard and long to deflect attention from one of the principal causes of technical failure in the nitrate industry. A thousand and one ideas have been proffered to solve the problem of what to do with the layer of sludge found underneath the crinolina and deposited during clarification in the chulladores (settling vats) and in the relave tanks. Dr. Donnan has an elaborate program prepared for his research department. An amazing fact again emerges: that investigators fail to realize that the process ceases to be leaching as soon as a portion of a charge is removed with the percolating liquor. The effluent is no longer a solution, and the material left in the vat does not represent the residue. Further, the abstraction of slime from the vat connotes channeling; the equilibrium of the charge is disturbed, making regular percolation impossible.

Assuming that other conditions are correct, the deposition of borra, or slime, from the leach liquors resulting from downward percolation is due to inadequate support for the charge. If the pioneers in cyanidation had practiced bulk treatment of comparatively coarse, dry-crushed material by leaching in a vat with a "filter" bottom of ⅜-in. holes, failure would have resulted in the same way as it has on the pampa. A proportion of the slime would have washed through, channeling would have resulted and extraction would have been poor.

The borra bogey has served to obscure an important fundamental fact—that physical considerations must be given primary attention. The first thing is to see that the process is working as such. If it be leaching, then percolation must be even; the effluent solution must be free from insoluble. Physical conditions must be arranged so that this is possible; consideration can then be paid to the question of efficient extraction. In Chile little or no attention has been given to physical considerations. Much finer grinding of the caliche has been suggested as a logical departure, in order that a charge may consist of particles of a size permitting even percolation, even dissolution of the nitrate and even drainage; but operators have pooh-poohed the suggestion, because, forsooth, more borra would be formed or released! Thus it is seen that the bogey crops up at every stage; it is used at every opportunity to frighten the interested visitor.

The borra in Chilean caliche of average composition is easily and inexpensively treated, provided (1) it is held in position throughout all stages of submergence, leaching and drainage; and (2) that adequate support is provided for the charge, permitting regular percolation and low moisture content in residue. Fineness of grinding must be such that there is no appreciable movement of borra in the direction of the percolating solution. Muddy liquors in Shanks-maquina operations are caused "(*a*) by the disturbance of the equilibrium of the charge by boiling or high-temperature maintenance in the cachuchos, and the freeing of an unnecessary amount of borra; (*b*) by uneven resistance to flow of solution through the charge, resulting in short circuiting; and (*c*) by the incomplete and unsatisfactory support for the charge by means of punched plates, leading to local collapse at numerous small areas and the washing through of borra and sand."[5] No investigation should be started until agreement is reached that muddy solutions are incompatible with correct physical conditions for leaching. Dr. Donnan, after summarizing the action in the chullador, says that "clarification presents a number of problems . . . very careful and scientific attention must be paid to these operations." A better, cheaper and safer plan would be to consider the production of solutions free from borra.

"If boiling and evaporation are to be prevented in the boiling tanks," suggests Dr. Donnan, "probably the best way to do this would be to close the tops and

SORTING CALICHE ON THE PAMPA

BRINGING CALICHE FROM THE PAMPA

MECHANICAL CAR TIPPING AT A PLANT

[4]Ibid., p. 6.

[5]Ibid., p. 10.

preheat the liquor between each leach." The removal of the steam coils and the avoidance of the external heating of solutions between vats was put in practice on an operating scale over 2 years ago. No investigation is necessary on the part of the proposed research department to determine the practicability of the step. As to closing the tops of the vats, I do not understand what is meant, although I have suggested[6] the use of float insulators on the surface of the solution to prevent heat losses from radiation.

Donnan Fails to Mention the Possibility of the Use of Grainers in Crystallization

Under the subject of crystallization, Dr. Donnan touches lightly on batea practice, dwelling primarily on the time factor. The heat loss during crystallization cannot be considered important, but I think that emphasis might well be laid on the fact that, because of large areas needed, the cooling of solution en route to the more distant bateas is inevitable. "Most of the heat available for evaporation is dissipated by conduction losses and direct contact with excess cold air. When the solution has reached such a temperature that evaporation is slight, the deposit of crystals on the sides and bottom of the batea prevents or delays the chilling of the liquor to low temperatures. Excessively large installations are needed to counteract the inefficiency of operations at every stage of the process."[7]

I was disappointed not to see some comment by Dr. Donnan on the possible use of grainers in Chile. The apparent advantages of their adoption would include "(1) reduction in area of plant required; (2) ability to grade product, from high-grade crystals containing caldo (with low salt percentage) as moisture, to the ordinary commercial nitrate; (3) elimination of all hand labor and the continuous and automatic delivery of crystals of varying grades, from pure nitrate to a commercial product; (4) avoidance of launder delivery of caldo for long distances, with reduction of radiation losses, prevention of formation of small crystals and high moisture percentage in product; (5) ability to control heat losses during the earlier stage of cooling, so as to obtain maximum evaporation of water; and ability to hasten the later stage when evaporation is slight."[8]

The Donnan Report Also Omits the Large Economy of Atmospheric Evaporation

The extended use of vacuum-pan evaporators in the nitrate industry is desirable and logical; but to my mind a serious omission from the recommendations for research is in connection with what is usually referred to as solar evaporation. I am still of the opinion that "Primary consideration must be paid to the possibility of utilizing the extraordinarily favorable atmospheric conditions prevailing at all seasons of the year on the Chilean nitrate pampa—the heating effect of the sun, the abnormal dryness of the atmosphere, the persistence of high winds and the almost entire absence of rainfall. These advantages indicate conditions that are highly favorable to solar evaporation. The feasibility of utilizing the evaporative powers of the air in conjunction of the sun-heating of thin layers of liquor at a negligible expense offers advantages that cannot well be disregarded. The problem confronting the industry as soon as the present high-grade deposits are nearing exhaustion will be in connection with the recovery of a commercial nitrate from a comparatively low-grade brine. The fractional crystallization of such a solution by solar evaporation and the production of an impure crystal must inevitably be an important phase of any scheme suggested."[9]

I carried out in Chile, on three separate occasions, tests on the evaporation of water from aqua vieja by natural means. At the time I had access to an unusually complete series of weather reports on another pampa, from which I judged that the favorable conditions I observed were not merely local. The evaporation amounted on an average to 9 liters of water per square meter of surface exposed per 24 hours. One test indicated that the evaporation amounted to 146 in. per annum. In another test it was found that the exposure of 1 sq.m. of aqua vieja resulted in the deposition of a heavy crop of crystals containing 89 per cent nitrate ($NaNO_3$). Other experiments proved that a considerable amount of commercial nitrate is obtainable from aqua vieja by this method, provided the evaporated water is replaced at the same time by more aqua vieja. At a certain stage, however, an impure crystal is deposited, after or just before which the brine might be returned to the treatment plant.

If the caliche is of high enough grade, and so long as an expensive method of evaporation is feasible, it appears impossible to interest pampa operators in a cheaper and equally effective alternative. Other saline industries have gone through the same experience; but, so far as I know, the technical men of the pampa and their advisors represent the only group determined to ignore the possibilities of natural evaporation. In Utah, an important brine deposit was a commercial failure when quadruple-effect evaporators were used; but by adoption of solar evaporation it was transformed into a technical as well as a commercial success. In the district in question the rainfall is about 3 in. per annum, the net evaporation being 36 in. In many parts of the Chilean pampa there is no rain, and the evaporation amounts to over 100 in. per annum.

Questionable Value of Separate Treatment of Fine Material

Considerable investigation is proposed to determine the advisability for the separate treatment of fine material subsequent to its isolation from the caliche. Expecting a gradual diminution in grade of caliche treated, I see no prospect for the ultimate adoption of any of the schemes proposed. If the removal of fines from ordinary caliche gives improved results, it is obvious to me that the methods in vogue for the extraction of soluble are at fault; for, in leaching, much of the fine material is needed to maintain the texture of the charge, to insure even percolation and to prevent channeling around the larger lumps. Segregation of fines involves heavy expense and waste of nitrate, or it necessitates the application of pressure or vacuum filtration. Paul F. Holstein, whose experience in this connection in Chile has been unusually complete, stated recently: "The past 10 years has seen much, on the whole, unprofitable experimentation with new processes, most of them attempts to apply bits of knowledge snatched from milling practice without any great understanding of the applicability of the methods. The use of filters of various types is an example of one of these unfortunate efforts. While the nitrate man has gained costly knowledge, his

enthusiasm has become much dampened as each heralded 'invention' went the way of its predecessors into the scrap heap."[10] I still think that "There is no justification for the extra expense involved in the classification of the small amount of slimy material found in normal crushed caliche and the treatment of the fines by any system of pressure or vacuum filtration. Owing to the refractory nature of the slime after the absorption of the nitrate solution and the difficulty if not impossibility of thickening or filtering a borra pulp by any known method, it is highly inadvisable to separate this from the sandy material, either purposely or as an unavoidable phase of any scheme of treatment adopted."[11]

Bouquets for the Gibbs Process Unwise

Dr. Donnan singles out the Gibbs process, now defunct, as forming probably "a genuine and courageous attempt to break away from the bonds of traditional practice"; investigators unconnected with names to conjure with in the recent technical history of the industry are apparently grouped as "would-be inventors or authors" who "fail to justify their ideas or suggestions by means of the publication of exact quantitative investigations. There seems little doubt," the professor continues, "that the vast majority of the so-called 'new processes' are simply paper propositions."

Visitors to the Chilean nitrate pampa should distribute bouquets with caution, for it may be possible that a genuine and intelligent attempt may best be made by the pampa technician to improve methods and processes by adopting an attitude of moral and intellectual honesty toward the researches of others and by a toleration of the views of "authors and would-be inventors" from divers phases of industry. Dr. Donnan's commendation of the Gibbs process at oficina Celia, "which he was unfortunately prevented from visiting owing to preoccupation with other matters," indicates an apparent divergence from a rule he has laid down for the guidance of others, to wit, that "on no account must the research department take any figures or data on trust. It is absolutely essential that they themselves should determine the data." Consistency is a jewel, especially among scientists.

The Recovery of Nitrate from Ripio Is a Promising Field

The problem of re-treating the ripio dumps of the Chilean pampa, we read, is one "which the research department must not leave untouched or unconsidered. They would feel very foolish if somebody came along some day and solved it over their heads." Dr. Donnan suggests that "Good systematic counter-current leaching in the cold, followed by recovery of the nitrate by refrigeration, might offer a solution or part solution of the difficulty."

Ripio might be described as caliche that has been impoverished of nitrate and enriched with salt and other compounds. Ordinary cold leaching would produce an exceedingly impure liquor, so far as nitrate was concerned; it would offer no opportunity for the selective solution of the nitrate to the exclusion of salt—an advantageous feature of the hot process. Dr. Donnan could find no reliable survey of the average percentage of nitrate in any dump in Chile, and hundreds of millions of tons of this so-called residue is scattered over the pampa. One can only conclude from this reticence that it will be voted bonanza material at some time in the future, when the industry has finished "picking the eyes" out of the deposit. I should say that the average nitrate content of the dumps of residue in Chile is about 9 per cent. It may be more or it may be less. I have heard many asservations of low ripio, but the absence of convincing data on total loss leaves me skeptical.

"In any case," states Dr. Donnan, "the result would only be the recovery of a dilute liquor." I see no reason for this conclusion. I found no difficulty in treating a typical ripio, with the following results: nitrate in charge, 7.8 per cent; nitrate in residue, 0.4 per cent; nitrate extracted, 95.5 per cent; time of treatment, about 24 hours. The ripio was crushed to about ½ in. The solutions used were aqua feble, relaves and the customary water wash. The first effluent showed that the abstraction of nitrate from the ripio amounted to over 100 grams per liter. The residue contained 13.3 per cent moisture.

Although some dumps may contain sections in which there is an excess of borra, it is probable that an aggregate taken over any considerable length of dump face would provide an excellent product for treatment. As a rule the average ripio is so clean that it might well form the body of a charge that included a proportion of refractory, high-borra caliche.

Alternative Methods of Operating the Shanks System

Advantages of Upward or Downward Displacement

Dr. Donnan asks whether "it would be an advantage or disadvantage to give up the original idea of a continuous slow downward displacement of denser liquor, and to circulate the liquor in each separate tank by pumps or other means." This question indicates an incomplete appreciation of the imperfections of Shanks-maquina operations. I maintain that: "Efficient displacement of solutions during leaching must take place either in an upward or a downward direction. This involves (*a*) pumping from vat to vat on any system of solution concentration; or (*b*) the erection of the vats at different levels. The latter practice would present obvious disadvantages. In the Shanks system an effort is made to secure displacement from vat to vat without recourse to pumping or variation in vat level. The result is that operations are considerably simplified, but at the expense of efficient displacement. . . . Caldo where formed is largely diluted with incoming caldillo . . . no true displacement takes place."[12]

The concentration of solution by pump circulation in individual cachuchos is already in practice in many maquinas, but in this case nitrate is removed by the solution to be put again in contact with the charge. It may be taken as an axiom that in all efficient leaching operations a progressive impoverishment of the charge is accompanied by a progressive diminution in nitrate content of the solution in contact with it.

Circulation of Liquor Produced Thermally

Dr. Donnan also asks: "Could external heating of the liquors be so arranged that upward circulation in each tank was produced thermally (after the well-known principle of thermal circulation) and not by pumps?" The "liquor" circulating from cachucho to cachucho in

[10] *Chem. & Met. Eng.*, May 17, 1922.

[11] "Recovery of Nitrate From Chilean Caliche," pp. 11, 12.

[12] Ibid., pp. 6, 7.

an ordinary Shanks maquina is so muddy that I do not know of any type of heater that would prove reliable for the purpose. However, if the fundamental principles of leaching are to be recognized, it may be mentioned that upward percolation is not only practicable but highly desirable, especially during the earlier stage of treatment. As a general rule, however, I am opposed to the use of pumps for the delivery of solution underneath the bed of caliche. The pressure fluctuates and often rises above the normal, thus disturbing the equilibrium of the charge, causing short-circuiting and poor average extraction. Gravity flow from a definite head is preferable, arranged so that the difference in density between the incoming and outgoing solutions is a little more than balanced. The great advantage of upward percolation is that the denser liquor resulting is delivered from the surface, thus obviating crystallization troubles in piping or other inclosed parts of the apparatus.

Desirability of Using Homogeneous Charge

Dr. Donnan has drawn attention to one of the weakest features of present practice when he calls for an investigation on the advantage of homogeneity of the material comprising the charge, both in regard to size and nitrate content. The nitrate, as a general rule, is not finely disseminated through the caliche. In a 20 per cent charge I have often seen masses of 60 per cent crystalline matter alongside 2 per cent costra. Thorough mixing of the various types of caliche usually treated is an essential preliminary to operations on an adequate unitary scale. A homogeneous charge, in so far as nitrate is concerned, is only possible after the adoption of much finer crushing than is practiced in a Shanks maquina.

Machinery Necessary in Finer Grinding

It is pertinent that attention should be drawn to the question of machinery suitable for the purpose. I am averse to rolls for the secondary reduction of caliche; they were tried at Chuquicamata and thrown out in favor of disk crushers. There is a great deal more minus 150-mesh material in average caliche than there is in Chuquicamata ore, so that consideration of the problem of the avoidance of unnecessary sliming should be more thorough on the nitrate pampa than it need be at the famous copper mine. Any earthy raw material—if crushed coarse, thrown into a "leaching vat" equipped with steam coils and a perforated-plate bottom support, submerged with solution, which is boiled—might be termed refractory; for it is certain that the disturbed slime would clog the space below the support and foul the solution abstracted for precipitation or crystallization, or sent forward to vats charged more recently. This is precisely what happens in the Shanks maquina. The trouble is due to the methods followed and the apparatus used; the borra is responsible for the resulting inefficiency because it is improperly handled. The cheap and efficient removal of soluble by gravity leaching necessitates the preparation of a mass that is evenly permeable. This condition can be obtained only by adequate crushing, thorough mixing and proper distribution; the permeability is obtained by the selection of suitable machinery, by the avoidance of overcrushing and the release of an excessive amount of slime.

Suggested Use of Cottrell Precipitators for Settlement of Dust Unnecessary

In discussing the question of the settlement of dust, Dr. Donnan suggests that it might be possible "to arrange the crushers in closed wind-channels or wind-passages, and to precipitate and catch the dust by Cottrell or Lodge electrostatic precipitators."

The accompanying photograph of a disk-crusher plant in operation was taken at an oficina commended by Dr. Donnan for its progressiveness. The escaping dust, which was of higher grade than the average of the caliche being treated, was distributed everywhere by the prevailing wind. I see no need for electrostatic precipitation. I think that the trouble could be lessened by the use of aqua vieja as a spray on piles of caliche, either on the pampa or in the bins. Incidentally, the evaporation of water resulting would save fuel. Dusting from a primary crusher is inevitable with small-scale operations. With large gyratory crushers, however, the dust problem is seldom insistent, even with the most refractory material. As far as secondary crushing is concerned, disk-crushers are especially suitable for arrangement so that no dust escapes into the atmosphere in or in the vicinity of the crusher building. If an attempt were made to solve the dust problem in the maquinas of the pampa, it would be found that one of the principal causes of damage to machinery, of dirt and general discomfort would be removed. Health and interest in the work cannot persist for long under the conditions obtaining in the majority of the oficinas.

Criticisms of Methods of Calculating Results Suggested in Donnan Report

If one thing is needed more than anything else in the Chilean nitrate industry it is the simplification of operations at every stage. Much depends on a quick and

NITRATE CANCHA WITH BELT-CONVEYING EQUIPMENT

SECONDARY CRUSHING PLANT

easy and comprehensible method of stating quantitative results which constitute an important check on operations. Dr. Donnan has incorporated some valuable mathematical calculations in his report, but unfortunately he has beclouded the application of them by the introduction of phrases that need considerable clarification. Thus we have the "nitrate extraction efficiency of the leachers" and the "tank efficiency," the latter being defined as "the percentage of the nitrate contained in the raw material which is obtained in the strong liquor run from the leachers (boiling tanks)." In the first place, "efficiency" is a word that should be used with caution on the Chilean nitrate pampa; in the second place, the amount of nitrate in the "strong liquor run from the leachers" is greatly in excess of that originally in the caliche. What is needed in the technical operations of any process such as caliche treatment is a recognition of the difference between theoretical extraction and actual recovery. The former indicates the amount of nitrate removed, as shown by analyses of caliche and residue; the latter is based on the yield of nitrate in cancha (drying and sacking platform) as compared with the amount sent to the maquina. The best indication of a satisfactory process is evidenced when actual recovery closely approximates theoretical extraction and when it is obvious that accurate sampling is feasible by ordinary methods.

Sampling Methods in Vogue on the Pampa

Dr. Donnan contends that the sampling methods noticed in use on the Chilean pampa usually were unworthy "of the time of Noah's Ark." Personally I think that this is a reflection on the care with which that gentleman selected his cargo. If he followed instructions, the result must have been a creditable example of early sampling, although it is possible that a number of smaller beasts escaped being counted when they rode in that famous two-by-two procession.

The average methods of sampling in vogue in a nitrate oficina operating the Shanks process are such that no reliance can be placed on the accuracy of the results. Many different types of ripio may be discharged to the dump, the nitrate in the portion coming from above the crinolina plates in the cachucho being used invariably as an index to the efficiency of operations. "Because of the difficulty of sampling so unhomogeneous a mass as the material fed to the cachuchos, the impossibility of estimating the tonnage of the various ripios discharged and the wide variation in nitrate content in the individual pieces . . . the actual yield of nitrate usually indicates a loss amounting to twice or even three times as much as the estimate of nitrate in ripio would seem to indicate."[13]

Quantitative Control a Practical Impossibility on the Pampa

In formulating an extensive program of investigations for the research department, Dr. Donnan maintains that every process, "be it good or bad, is under *accurate quantitative control.*" I repeat the italics, but I maintain, in the Shanks process, that though this may be possible theoretically, it is impracticable when considered as an everyday phase of routine duties. Take, for instance, the question of the estimation of nitrate in borra, which is correctly described as a semi-liquid sludge with 16 to 25 per cent of nitrate. The nitrate may occur in small lumps of untreated caliche, as a strong solution, as original or redeposited crystals, as adsorbed salt or associated moisture in contact with colloidal clay and granular sand. This sloppy though valuable mess is usually shoveled into dump cars placed below the discharge doors of the cachuchos. To avoid undue spilling, the cars are loaded only about half full; the borra consists mostly of coarse sand and nitrate crystals in the bottom, with slime pulp and fine sand of varying densities at different levels. Correct sampling and tonnage estimation is impossible. The mass is of varying nitrate content and the car is usually caked with old ripio. The conditions of dumping are dirty and unsatisfactory; if the research department evolves during the day a scheme for the correct estimation of nitrate so discharged, it will be disregarded during the first night shift. To expect intelligent men to maintain enthusiasm over such a job connotes a disregard of the fundamental fact that a so-called leaching process which delivers a residue (*sic*) in such a condition is either being operated badly or is entirely unsuitable for the purpose.

A glance through Dr. Donnan's report will convince one that standardization of weights and measures is unknown on the Chilean pampa. Not only does this involve a pitiable waste of time and labor, but many of the results are valueless for comparative purposes. In few other industries are the advantages of adopting the metric system so obvious; if a research department be formed, the members should be permitted no personal latitude in this respect. Opponents to the metric system often maintain that it is seldom practicable to displace entirely the older units. In Chile it is mentioned that though the metric system may be used for control work, the final record of salitre (commercial nitrate) must be given in terms of the Spanish quintal of 45 kilos. This anomaly, one is glad to note, has now been overcome and the association is quoting all prices per metric quintal of 100 kilos.

Field for Scientific Research

I am, and always have been, a vigorous supporter of scientific research, not hit-or-miss experimentation; but I also believe that much depends on the careful selection of a promising field for investigation in the first instance. The prospective group of doctors of science and philosophy proposed by Professor Donnan might well spend their lives, until the pension age was reached, and their children and grandchildren after them, in obtaining scientifically accurate information about the working of the Shanks process under the varying conditions obtaining in the two hundred odd oficinas on the Chilean pampa, only to confirm existing knowledge—that, in nine cases out of ten, it is hopelessly inefficient.

Thanks to the initiative of the sponsor of the Shanks process in Chile, James (Santiago) Humberstone, the method has well served its purpose; it has enabled the industry to reach a high state of prosperity; and it has been responsible, in no small measure, for Chile's present-day position in the front rank of progressive nations. Conditions, however, are changing rapidly. The beds of caliche remaining untouched must be classed, for the most part, as either too low grade or too refractory for successful treatment by existing methods. In my opinion the best thing that could happen to the industry, except possibly in a few isolated instances, would be for everyone concerned to forget the Shanks process.

Improved Automatic Regulator for Pressures Below Atmospheric

By W. A. Jacobs and P. A. Collins*

In the examination of crude petroleum and some of its products, it is frequently necessary to obtain high-boiling fractions that cannot be distilled without decomposition ("cracking") at atmospheric pressure. Dean and his co-workers[1] state:

> The separation of the residue boiling above 275 deg. C. (527 deg. F.) or 300 deg. C. (572 deg. F.) into further fractions of various ranges of volatility can be made without cracking either by a steam or a vacuum distillation. Distillation in the presence of a current of open steam is almost universally used in commercial refining and frequently in the laboratory. In connection with a quantitative analytical method, however, there are numerous complications and it seems preferable to use the scheme of vacuum distillation. Either of these methods accomplishes the same fundamental purpose of reducing the boiling point of the oil. Boiling occurs when the vapor pressure of the oil slightly exceeds the pressure of the atmosphere above it. The temperature at which a liquid boils can be lowered either by balancing part of this atmospheric pressure with the vapor pressure of a current of steam, or by reducing the atmospheric pressure by means of an evacuating pump. The latter method permits easier control and is more suitable in the laboratory.

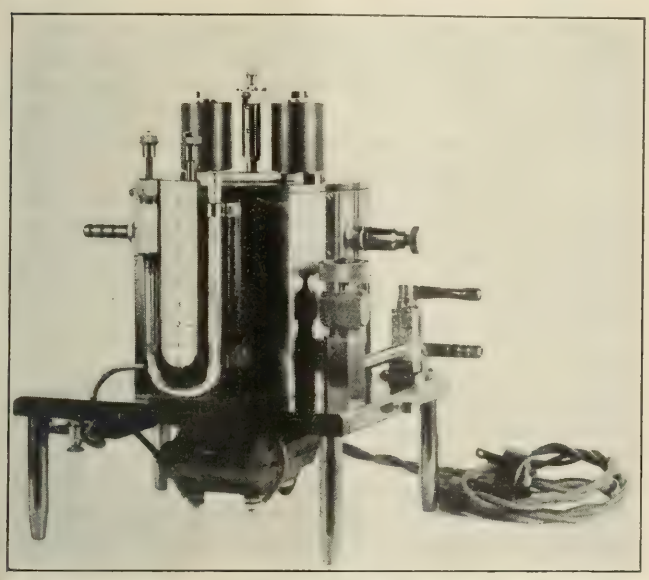

FIG. 1—PRESSURE REGULATOR DEVELOPED BY BUREAU OF MINES

This same bulletin describes the apparatus and methods used in making vacuum distillations, and describes two types of manually operated and one automatic pressure regulator for maintaining a constant "vacuum." The actual pressure used for this class of distillations in the bureau laboratories is 40 mm. absolute, which corresponds at sea level to a "vacuum" of about 28 in.

The automatic regulator described by Dean was entirely successful and has been in use for over 2 years in one of the bureau laboratories. It has, however, been necessary to build additional regulators from time to time, and a number of improvements have been incorporated in each one, so that the latest model is considered much more simple to construct, more compact and neater in appearance, more sensitive and more foolproof than any of the earlier models.

The principal parts of this regulator are a cylinder 4 in. high made of 5-in. brass tubing with sealed ends, which serves as a reservoir, two electromagnets which operate the air inlet valve, a main valve, supplemented by a needle valve, on the tube connecting with the vacuum pump, a 110 to 6-volt transformer, a fixed condenser to prevent "sparking," outlets for connecting to the distillation system and to the vacuum pump, and an adjustable regulating manometer equipped with a movable scale. The adjustable manometer makes it possible to carry on distillations at different pressures at will.

Working drawings of this apparatus have been completed, and its manufacture will probably be undertaken by several of the apparatus supply houses. Fig. 1 shows practically all parts of the apparatus.

Patenting Process for Wire

A paper recently read by R. C. Helm before the American Iron and Steel Institute entitled "Use of Liquid Fuel in Metallurgical Furnaces," contains some interesting information on the so-called patenting process used to soften and toughen wire before drawing it through dies, and the kinds of furnaces usually installed for performing the operation.

"Old process" patenting is effected in a continuous furnace in which the rod or wire is heated to 1,700 deg. F., then cooled in air. In "double lead patenting" the rod is passed through a lead bath heated above the critical, and immediately passes into another at a temperature just below the critical. The latter scheme gives the strict temperature control necessary for high-carbon material.

Older coal-fired furnaces were made of massive brickwork to act as a heat reservoir so that variations in firing would have less effect on the metal. Long narrow furnaces were used; the flame passed lengthwise from end to end, then back through an upper compartment, escaping at the fire end. Wire or rod was threaded through small perforations in the fire arch, as shown in the sketch, Fig. 1.

Less coal is burned if the wire passes through the upper compartment, bathed in the waste gases. When using oil fuel the lower compartment may be flared out from the burner, and the hottest portion of the furnace is then at the end discharging the wire.

Double lead patenting is done in furnaces of the same general type. The high-temperature pot is placed over a perforated arch at the end of the furnace farthest from the burner. Spent gases travel back again above the fire arch in opposite direction to the cold wire as it enters, giving it a preheat before it enters the pot. The second or cooler pot is placed just beyond the furnace and is heated largely by the hot wire entering it. A quenching furnace has a bath of cold oil in place of the second lead pot; hardened wire then passes into a separately heated oil bath to draw the temper.

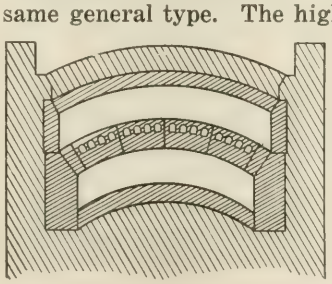

FIG. 1—CROSS-SECTION OF COAL-FIRED PATENTING FURNACE

Trademarks

What Is a Trademark?—Brand Marks Versus Names of Products—Why Select a Word for a Trademark Which Cannot Be Exclusively Appropriated?—Why Undermine One's Business Good Will by Using a Trademark as the Name of a Product?

By Clayton L. Jenks
Patent Attorney, New York City

STRANGE customs are growing up in the advertising field which unless checked will either store up future trouble or require a modification of our trademark laws and a reversal of our court precedents. The difference between a trademark and a name of a product seems to be misunderstood not only by chemists who should know how to protect their marketed discoveries but even by many advertising and sales men who originate trademarks and are supposed to be their foster-parents. How many people can analyze and define the trademark rights involved in the following well-known words: Aspirin, Bevo, Castoria, Cascarets, Celluloid, Coca Cola, Coffee, Colgate's, Corn Flakes, Elgin, Fatima, Featherbone, Ivory, Kodak, Linoleum, Lux, Lysol, Mazda, Mazola, Pantasote, Postum, Pyrex, Pyroxylin, Quaker Oats, Resinol, Sapolio, Shredded Wheat, Singer, Vaseline? What is a trademark?

A tribe of Indians acquired a fancy for a certain brand of cove oysters put up in cans which bore on the label a picture of a dog's head. Being uneducated denizens of the prairie and unfamiliar with the taste of sea food near its native habitat, they have always believed that this particular delicacy was canned dog, and woe unto anyone trying to palm off other brands for their beloved dog!

Absurd as such an interpretation seems, a large number of educated people are similarly using trademarks as names of products and deliberately undermining their own businesses. Why did "linoleum" change from a valuable exclusive trademark asset to a mere common name of doubtful value? In the average popular magazine, on the street cars, everywhere, one sees advertising built around some special word which either is inherently unfitted for use as a trademark or, originally being a good trademark, is improperly used. Why is it that many a business good will is built upon quicksand when rock foundations are freely available? There is a surprising amount of ignorance as to the function of a trademark, and yet the whole subject is based upon a few simple fundamental principles which should not be ignored.

Origin and Function of Trademarks[1]

From the time of the Neolithic age there has been a strong necessity for identifying particular manufactured goods. The stones of the walls of Pompeii and pottery found in Egypt, dated from 6000 to 1200 B.C., have borne crude illustrations of horns, trees, jugs, bees, animal heads, etc., which were used as trademarks. It is interesting to note that similar trademarks found in Greece, Upper Egypt and Hungary have indicated a common civilization around the Mediterranean long before Egypt acquired a civilization of its own. A jar of fish sauce found in Pompeii bears the inscription "Scaurus' tunny jelly, Blossom Brand, put up by Eutyches, slave of Scaurus." Note the use of the proprietor's name as well as the special trademark "Blossom."

As that particular tunny jelly sold in Pompeii, or the Damascus sword blade or a clay brick made in Moses' time became known for especial merit, naturally the purchasing public demanded some identification mark on the goods so as to know whether the salesman was trying to substitute something "just as good" for the original satisfactory product. Likewise, the maker of the jelly, the sword or the brick realized the advertising value in getting the public to look for his mark and ask for his goods; hence from the beginning of trade, other than in local bartering, there has always been a reason for using a trademark.

Use of Marks Explained

In early times the maker could not write his name and customers could not read it, hence the peculiar mark put on the sword blade or the brick served as his signature for identification purposes. Moreover, it indicated that goods so marked were of his best workmanship and that he was not ashamed of them. Naturally, if he were making poor products he would attempt to sell them by surreptitious methods.

We today have the same method of branding, particularly on goods such as nails and small tools, which are not capable of carrying long names or elaborate picture designs. However, the main difficulty with wordless marks is that the purchaser has no ready name for the mark and so must see the goods for identification and point them out to the salesman. Obviously, this tongue-tied system has its drawbacks. Hence such symbol marks are more ordinarily used in association with words, such as the peculiar mark found on the end of the cracker package put out by the National Biscuit Co. which is labeled "In-er Seal." Similarly the brand of evaporated milk which bears the picture of a bird carries the name "Eagle" so that one may not mistake its identity.

Ordinarily a word is used without illustration and it is in this use of words alone that our modern difficulties largely arise. The purchaser of Eagle condensed milk knows that he is obtaining the milk of cows. Similarly a buyer of Star soap knows that it is not of stellar origin. On the other hand the average person may not know that Aspirin is not the chemical name of the product and that the material is in reality "acetylsalicylic acid." It is this use of the trademark as the name of the product, due to the manufacturer's failure to provide a satisfactory name or to the public's indifference or its inability to understand correct trademark usage, that works the greatest harm.

A trademark is a part of the intangible good will which the public holds toward a business person,

[1] These historical data were derived from Rogers on Good Will, Trade-marks and Unfair Trading, published by A. W. Shaw Co. of Chicago. This book gives a clear non-technical exposition of the subject and is well worth reading.

whether individual or a company, who makes or sells a branded product. It is the first and main duty of an advertising man to build up and safeguard this good will. The owner of the business should know whether that good will is being injured or fostered. The prime purpose of advertising is not to obtain an order here and there, but it is to educate the public as to the use and advantages of a new article and the manufacturer's business service, to arouse a popular interest in both the company and its goods, and to create a potential friendliness or good will which ultimately results in prosperous business. A trademark from this viewpoint should be the most prominent part of the advertising, which is meant to remain clear in the mind of a potential purchaser. The latter is not supposed to remember all the virtues of a particular trademarked article, but if he acquires a good impression from reading the advertisements, he subconsciously carries that good impression intertwined in his mind with a word which is prominently displayed, whether it is the trademark or some other word. That word should be the trademark.

Haphazard Choice of Mark

When a patented article is first put on the market, and particularly a chemical product, the organizers of the company may appreciate dimly the advantages in having a good trademark; yet they may carelessly select some word which cannot be registered or they may deliberately misuse a registrable word as a mere trade name under the delusion that the name will always be their exclusive property. Unless a careful preliminary study of the trademark situation is made, many and serious difficulties may arise in later protecting the business good will.

It is a common occurrence for a new trader in the field to go to the expense of adopting a trademark only to find that he is infringing another's rights and is subject to an injunction stopping his business and to an accounting of his profits. Not only should the utmost care be taken to insure having a proper word which does not infringe and using it correctly, but one should, as far as possible, test the psychological effect of the use of the word upon a large number of persons representing the purchasing public and otherwise endeavor to determine its advertising advantages.

As a serio-comic illustration of the possibilities for trouble inherent in a trademark, the American name of an automobile proved unpopular in Spanish countries during the early days of the industry, when automobiles were both a novelty and a menace. Upon investigation it was found that the translated name meant "criminal"!

It is a common error for a new trader to choose a word which describes the article or its advantages. If the product is a new shaving soap, he may decide to call it "Heavy Lather," or if a razor, "Fast Shaving." Or, weakly following the custom in his particular art, he may mall a floor covering "Baboleum," indirectly suggested by the popularity of "Linoleum." In the latter case, thinking possibly that Baboleum is the name of his floor covering, because Linoleum is a name, he sticks a blue label on the back of the rug and misguidedly advertises for the public to "look for the blue label," totally failing to realize that there is little trademark value in any such spot of color and that whatever the public retains from reading such advertisements or seeing such labels is centered, not around the blue color, but around the main word "Baboleum."

Such a manufacturer is headed toward trouble. Some competitor, realizing the strides of this first man's business, may decide that he too must market a "heavy lather soap" or a "fast-shaving razor" and he puts out competing products and so uses the same words to describe his goods as to draw a share of the trade. The first man, taking his aggrieved feelings into court, finds to his surprise that he cannot monopolize any such description as "Heavy Lather" or "Fast Shaving"; and the court merely mildly enjoins the competitor from unfair practices, but leaves him open to the free use of such descriptive words. Then all that is left to the first man is his own business name, which may not have been emphasized in the advertising and which will now cost a large sum to get it properly before the public.

The word "Aspirin" as found on a drug used to mean that the material so labeled was made by the Bayer Company. The court has, however, recently decided that the trademark word was a common name so far as concerned the retail trade, so that a druggist might sell "Aspirin" of any company's make under that name. As a result the original users of the mark were obliged to undertake a campaign to advertise the name "Bayer" and ask the public to "look for the Bayer Cross" made up of the two words "Bayer" arranged in a cross shape on each tablet. Why was this trademark "Aspirin" thus thrown into the public domain?

Trademark—A Common Law Right

It is difficult to understand why the originators and users of a trademark do not appreciate the value of a word mark capable of being monopolized or why they are so shortsighted as to build up a trademark only to lose it. A trademark should last as long as the business lasts. Perhaps such people have vague dreams that a descriptive word such as "Fast Shaving" for razors or a mere dictionary name might be retained exclusively in their business, but common sense considerations should teach them otherwise. Trademarks are founded not so much on a large body of laws and decisions, which indeed there are, as upon ordinary everyday common sense, and the function of the court in the average trademark dispute is merely to apply that same judicial common sense.

A patent is a right granted by the government under which a monopoly for 17 years is obtained for excluding others from making, using or selling the product of an inventor's brain. The monopoly ceases at the end of the period and the public thereafter has full rights to the invention. Similarly, an author or artist may obtain a copyright monopoly giving him the sole right to publish or make copies of his work for a limited time. Patents on inventions and copyrights on writings and paintings are monopolies created by law. A trademark, however, implies that there is no monopoly and that the mark is used to distinguish the goods of one maker from similar goods of a competitor. There is no monopoly except in whatever rights a user has to the trademark itself.

A trademark is a designating symbol or word which stands as a short signature of a manufacturer, as a means of indicating the origin or ownership of goods, as a memory guide to which the public attaches its good will for a particular make of goods, and at times as a sign of quality and guarantee of the trader's good will toward the public. One chooses a trademark, therefore, to identify his own goods and differentiate them from those of his rivals.

A trademark is not a government-granted right. It

is a common law right. It is a squatter's right, an explorer's right. He who first penetrates a new land unclaimed by others, under the law of all time, is entitled to that land. This is a fundamental principle embodied in the very make-up of the human being. Similarly, when a person adopts a trademark, he is pre-empting and claiming exclusive rights to a field never before occupied; but let him see that there are no adverse claims to his field when he enters it and that the public be not allowed to trespass later. Therein of course lies his danger.

Two Classes of Trade Words

With these principles in mind, it is now seen that a partial answer to our main question is that there are two classes of words used as trade symbols: (1) technical trade or brand marks; and (2) trademark names.

A genuine technical brand mark is easily picked out. These are the words which truly indicate the origin of the goods and stand as a short signature for the manufacturer's or trader's name. For example, Old Dutch Cleanser, Eagle milk, Quaker oats, Lysol disinfectants and soaps obviously comprise strong brand-marks.

The term "trademark name" is used herein in a narrow sense to indicate that class of trade words which are used as names of products, but which have trademark functions and indicate the manufacturing or sales origin of the goods. A name of a product, unless it has trademark qualities, is not registrable, or if it has been registered may be later removed from the official records, when it no longer serves as an exclusive designation of origin. Originally, linoleum was a trademark. It was used as a trademark name. Now it is a mere common dictionary name without trademark value.

A further class of words relate to a business and its good will rather than to a particular commodity. Such trade names as company names may become of great value, but unless they are registrable as exclusive trademarks, they serve but poorly to protect one's business. If the company name has been arbitrarily coined, it may ordinarily be maintained as an exclusive mark; but if it is a common name like Baker or Rogers, the difficulties involved in keeping all other Bakers and Rogerses out of the same field are formidable, as has been the case in connection with the use of these names in the chocolate and silver industries, respectively.

When a new chemical is discovered, it is given a name, like the name of a basic element, and this name is necessary for the public to use in referring to that particular material. Everyone has full rights in using that name and no one may use it as an exclusive trademark. On the other hand, a trademark is supposed to identify a particular business and certain goods of a trader, and not to apply to similar goods made by one's competitors. Unfortunately, many chemical manufacturers in marketing a new and unnamed product do not provide both a name and a trademark but economically try to make one word do for both. It will not do! Remember that a trademark is the signature of a person and not the name of an inanimate object. A trademark name has not all the characteristics of a trademark; hence the public or a competitor may some day tear down whatever good will lies in that word and use it merely as a common dictionary word descriptive of a product made by anyone.

We shall not attempt to point out the strong as distinguished from the weak trademark names, as the distinctions are very fine, and some of the weak ones may yet be reclaimed before it is too late. How this can be done after one has let competitors into his trademark field is not the purpose of this article. Suffice it to say that the way is rough and stony.

Trademark names should be considered from two viewpoints, depending on whether they are applied to patented or unpatented products.

Patented Products

When the original makers of "Linoleum" floor covering marketed this product, they coined an arbitrary word to designate it and theoretically had a good trademark. They had, but they did not use it as a trademark exclusively. This floor covering was a new product, and patented so that no one else could make it. Instead of adopting a separate descriptive name by which the public might differentiate it from all other flooring materials, the makers chose to use their exclusive trademark "Linoleum" as a trademark name and the sole name of the product. When the patent expired and others had a right to make the flooring material, they had no other name for this material and naturally adopted the same word "Linoleum," merely stating that this was "Smith's" or "Jones'" Linoleum instead of the product made by the original Linoleum company. The court upheld this state of affairs, holding that since there was no common name for the material which the public could use, it had a right to take the name which had heretofore been considered a trademark by its owners and use such name in a descriptive sense to name the flooring material; but competitors of course were obliged to make it clear to the public that they were not the original company.

Following this decision the courts have thrown into the public domain such trademarks as "Castoria," "Singer," "Featherbone," "DeLong" (hooks and eyes), "Webster" (dictionary) and "Aspirin."

In the Castoria case, the court held that the name Castoria as first used by Dr. Pitcher may have been indicative of the manufacturer—i.e., have trademark functions—during the life of the patent, yet when the right to manufacture and sell the compound became universal anyone might call his compound of the same formula by the name Castoria. It should be particularly noted that "Castoria" was used by Pitcher for 10 years after his patent expired before the second man adopted it, nevertheless the court held that this matter of time made no difference. Since the word had become the name of the thing and public property, it could not thereafter be reclaimed as a trademark.

In connection with the Singer Sewing Machine, it was decided in an opinion rendered by the late Chief Justice White that the name "Singer" indicated to the public a class and type of sewing machines and so was generally descriptive. The court, however, held that while others might use the name Singer if they made the identical Singer machine, nevertheless this right was subject to the condition that the name must be so used as not to deceive the public into mistaking the second manufacturer for the original Singer company.

Similarly, copyrighted names are subject to seizure by the public; as decided in the famous Webster Dictionary case. During the term of the copyright the proprietor has a monopoly of the book as well as the name, but both name and book pass into the field of public right when the copyright expires. However, it is to be emphasized that the court endeavored to protect

the G. & C. Merriam Co., the original publisher of the Webster Dictionary, by holding that the word had acquired a secondary trademark meaning by the public's acquiescence; hence *prima facie*, the second man was not entitled to use the word except under rights which were secondary to those of the Merriam company. That is, he must neutralize any false impressions which might be created and unmistakably inform the public that the book is of his own publication and not that of the Merriam company. The courts therefore place the burden upon the second man and not upon the first user of the trademark to distinguish between the two makes of goods.

It may, however, be stated as the law of the English-speaking nations that a trademark which is used as the name of a patented article will become public property when the patent expires, if such word is the sole name by which the public has come to know the patented article. It is of vital importance that manufacturers understand this theory of trademark usage. Anyone checking up the advertising in the average popular magazine or cards in the cars will find a great many trademarks which are going headlong into the public domain. Some advertisers are so kind to the public as to place their patent dates on the trademarks, telling when the patents expire! The failure of advertising managers and salesmen to understand this danger is appalling, considering the immense sums of money which they are expending in building up such trademarks, merely to have them taken away by a competitor when their patent rights are gone.

Unpatented Articles

As to the unpatented products, the courts have attempted so far to protect the trademark names applied thereto, but Lord Kay in his famous summary of the law of names has stated that if the maker of an unpatented article has slept upon his rights and permitted the name to be used by others until it has become public property, the court will not interfere. Moreover, it is difficult to say how far away is the day of reversal of the former lenient attitude of our courts and legislatures. Attempts have already been made to destroy many valuable trademark rights. For example, as a result of the German chemical situation, a bill was introduced in Great Britain in November, 1917, to amend the trademark laws. This bill, which was sponsored by such prominent men as Lord Parker, a leading judge, and Sir Albert Stanley, President of the Board of Trade, provided that a word trademark used as the name of an article should be removed from the Register of Trademarks. The chief reason underlying this bill was that if a trademark were used as a name it thereby gave a perpetual monopoly of a business so that it would be impossible for competitors to get on the market unless they could use these same household trademark words. In their panic the British misconstrued the nature and function of a trademark and proposed to go back to harsher rules than ever before applied and they even extended their ill will to cover well-known American trademarks. The protests from this country and the final calm judgment of British business men and attorneys ultimately killed that portion of the bill. It was considered that, with due regard to business ethics and fair play, every new man in the field should build up his own trademark and not attempt to profit by the advertising good will of the earlier competitors. We have, however, no guarantee that such a hostile theory of trademark usage may not some time be enacted into law. Small manufacturers are likely to back trademark legislation which penalizes any large manufacturer, and anti-trust laws may go to the extent of declaring our well-known trademark names to be public property.

This British belief concerning the monopolistic nature of a trademark business—this does not refer to the monopoly in the word itself—seems to be echoed in the minds of many American advertising men—i.e., if they use a trademark word as the sole name of a product, they thereby acquire a perpetual monopoly in that product without regard to their short-lived patents. But in their overzealousness they defeat their own ends. Peculiarly, they do not appreciate the fact that a trademark properly used is a perpetual right, and they strive to attain something even greater than a trademark, which will give them not only a trademark monopoly but a perpetual quasi-patent monopoly as well. The fallacies underlying their beliefs are clear. First, there is no perpetual monopoly in a trademarked business, since obviously if the original makers should change their product and put out an inferior grade, or, as is more likely, if some new product appears which tickles the popular fancy, then competition must be faced and new trademarks will rapidly come to the front and undermine the original business. In the second place, the use of the trademark as a name negatives the idea of monopoly, since a name belongs to the public and does not primarily indicate the origin of the goods. As the advertising of a trademark name progresses, the more familiarly the public uses it; hence the more popular the mark the more insecure are the trader's rights in it.

It must not be understood from the above discussion that trademark names will not be protected by the courts. On the contrary, our courts will go a long way toward helping a man out of his difficulties by ascribing a secondary trademark meaning to a trade name. Moreover, one may perfectly properly decide to use a trademark as a name and he will be protected from unfair competition and the unethical practices of competitors trying to capitalize for their own benefit the advertising good will which the first man has built up. Many well-known trademark names are so valuable that it would be a harsh court indeed which would throw such words open to the public; yet we have the "Aspirin" and "Linoleum" cases as warnings that a trademark name, however popular it may be, may under certain circumstances be legally held to be a part of the public domain.

An analysis of the trademark situation for a manufacturer about to enter the chemical field may resolve into the question as to whether he can obtain greater commercial advantages by using his trademark as a name or by using it purely and solely as a brand mark for a described product. The answer should come easily. Merely by describing his product, giving it a name and using his trademark as a brand mark, he can protect the business good will. Why, if it is so easy to do the thing right, should one wish to take chances? It is not ordinarily difficult to describe a product, however complex its composition and structure may be. The public does not demand and in fact does not want a detailed description of the goods it purchases. For example, "Pepsodent" tooth paste bears the phrase "pepsin-bearing tooth paste" as the name of the material. This undoubtedly is sufficient description, since a chemical analysis of the actual ingredients present is

of no interest to anyone but competitors, who can make their own analyses.

The point is: Use some kind of a descriptive name to describe your goods so that the public will not think that the trademark is a mere name and so seize it for its own use. Surely, one's advertising campaign is as effective and the popularity of the goods as easily assured if the goods are identified by a proper trademark instead of a trademark name. No one can gainsay the popularity of such well-known brand words as Ivory and Fairy for soaps, Gold Dust for washing powders, or Fatima for cigarettes. These are proper trademark words and are clearly not the names of products.

If one but remembers the customary usage of trademarks as built up from the beginnings of trade and use the words as brand marks which specifically identify and distinguish one man's goods from another's, he cannot go far wrong. To furnish such identification, the trademark word must be carefully selected so as to be capable of exclusive use and then its user should fight with all his powers to keep competitors out of his domain, and to educate the public to know that such trademark always stands for a particular line of goods and as a synonym for the trader's name.

RÉSUMÉ

A trademark is a brand mark, a short signature, a mark serving to identify the maker and the origin of the goods. It is not the name of a product. It is one trader's brand of that product and should be used to distinguish his goods from another's. A trademark implies competition, not monopoly. It distinguishes between competing goods. Why try to use a personal signature as the name of an inanimate object?

Legal Notes

BY WELLINGTON GUSTIN

Decision on Chemical Control Act Not Reviewable

In a recent case the Court of Appeals of District of Columbia has upheld the ruling of the Secretary of the Treasury of the U. S. on his interpretation of the dye and chemical control act, approved May 27, 1921, saying that the Secretary has the implied authority to interpret the act because that is necessary to the performance of his administrative duty. This act operates to extend a privilege to manufacturers of certain chemicals and their substitutes, and Congress rightfully fixed the conditions under which the privilege should be enjoyed, one of which was that the Secretary of the Treasury should administer the act.

FUSEL OIL HELD NOT TO COME UNDER ACT

The provision in dispute was title 5 of the act, which reads: "No synthetic organic drugs or synthetic organic chemicals shall be admitted to entry or delivered from customs custody in the United States. . . . unless the Secretary [of the Treasury] determines that such article or a satisfactory substitute therefor is not obtainable in the United States . . . in sufficient quantities and on reasonable terms as to quality, price and delivery," etc.

The Secretary issued an order on Sept. 30, 1921, that fusel oil should not be considered to be a synthetic organic chemical within the meaning of the act and that permits for its release from customs custody were not required.

Exception to this order was taken by the Commercial Solvents Corporation. This company manufactures, at its plant in Indiana, butyl alcohol, which it claimed could be used, and was in fact being used, by practically all of the former users of fusel oil as a satisfactory and efficient substitute for that oil. It contended that fusel oil is a synthetic organic chemical and that its entry into the United States is prohibited by the act, since the corporation's plant had ample capacity to manufacture a satisfactory substitute for it and is able to supply all the needs and demands for such oil, and offers the same for sale at a reasonable price, and on even and equal terms with all purchasers, having regard for the quantities of their purchases, any difference in price being merely sufficient to equalize the difference in the cost of selling in large or small quantities. It also alleged that, if the Secretary of the Treasury should permit the importation of fusel oil in accordance with the order mentioned above, the company would sustain great loss and damage. Hence the company came into court to obtain an injunction forbidding the Secretary to give any instruction to any Collector of a Port of the United States permitting the importation of fusel oil except in the special cases provided for in the act. The Supreme Court of the District of Columbia refused the injunction and the Commercial Solvents Corporation appealed.

SECRETARY'S DECISION NOT REVIEWABLE

The corporation alleged that various importers and would-be importers made representations to various bureaus and officials of the Treasury Department to the effect that such oil is not a synthetic organic chemical; that these representations were considered by such officials as Chief of the Dye and Chemical Control Section, Chief of the Customs Division and Secretary of the Treasury. Further it alleged that the Secretary decided that fusel oil was not a synthetic organic chemical and that its importation was not prohibited by the act. It also alleged that this decision, made after the consideration just mentioned, was not correct and asked its reversal on the assumption that the court has the right to exercise its independent judgment with respect to the facts set forth in the bill and decide the case on its merits—in other words, that the court has a right to substitute its judgment for that of the Secretary, if it thought he was wrong, even though he was acting within his jurisdiction when he rendered his decision.

The Court of Appeals upheld the lower court in its holdings. The authority given to the Secretary by the dye and chemical control act to administer that act carries with it the implied authority to interpret it, because interpretation is necessary to the performance of his administrative duty. Nor can the courts review, by mandamus or by injunction, a decision of the Secretary of the Treasury, made within his jurisdiction, to interpret the chemical control act, if he did not act in a capricious or arbitrary manner. The Chemical Solvents Corporation did not charge or contend that the Secretary acted in a capricious or arbitrary manner, and it has been established in other cases that whether the Secretary's decision be right or wrong, that is not the question. It is his duty to decide as he thought the law was and the courts have no power whatever under those circumstances to review his decision.

Determining Combined Nitrogen in Iron and Steel

By Louis Jordan and F. E. Swindells
Chemist and Assistant Chemist, Bureau of Standards

THE only form of nitrogen ordinarily determined in steel is that combined as nitride, either of iron or of some of the other constituents. Tests for the presence of hydrocyanic acid or cyanogen on solution of steel in acid have been negative[1] and all the combined nitrogen is generally regarded as being present as nitrides. It is readily conceived, however, that part of the nitrogen present is not combined, but is either dissolved, adsorbed, or mechanically held. Iron, manganese or silicon nitride may be present in an ordinary steel; others are possibilities in alloy steels.

Allen Method for Combined Nitrogen

The usual method for the determination of combined nitrogen in steel is a modification of that employed by A. H. Allen[2] in 1880. Allen dissolved the sample of drillings or millings in hydrochloric acid of specific gravity 1.11. When solution was complete, it was made alkaline with lime, the ammonia distilled off and determined with Nessler solution. H. Braune[3] employed this same method, but specified that the solution should be filtered before distilling. He also used caustic soda in the distillation instead of lime.

In the 1918 edition of Blair's "Chemical Analysis of Iron and Steel" the Allen method is given with several modifications made by Langley, chiefly in the treatment of the caustic soda solution with a copper-zinc couple to remove nitrates and nitrites. Boussingault[4] had called attention to the fact that nitrates and nitrites during distillation were partly reduced to ammonia by the ferrous hydroxide present.

Another method for the determination of the ammonia in the distillate was proposed in 1907 by Petren and Grabe.[5] This consisted in collecting the distillate in standard sulphuric acid, the excess acid being determined by the addition of potassium iodide-iodate solution and titration of the liberated iodine with standard sodium thiosulphate solution. Hurum and Fay[6] have recently recommended the iodide-iodate modification of the Allen method for nitrogen determination.

In 1915 Tschischewski[7] studied the Allen method and made several improvements. He used standard sulphuric acid to collect the distillate containing the ammonia and titrated the excess acid with standard alkali. He had previously objected to the use of the Nessler method for the determination of the ammonia in the distillate because of the probable presence of amines.[8] He also pointed out the probability of error from alkali dissolved from glass condensers, and warns against unprotected rubber stoppers in the distillation apparatus if the Nessler method is employed.

As has been stated by Tschischewski, the size of the blank correction in this method is greatly influenced by the kind of condenser tube employed. Tests made at the Bureau of Standards with glass condensers have given after blank runs an amount of alkali in the distillate equivalent to 0.0001 to 0.0002 gram of nitrogen. The same solutions used in blank determinations with block tin condenser tubes have given only 0.000015 gram of nitrogen. The high blank with glass condensers is, however, quite constant and satisfactory duplicate results are obtained by carrying out two determinations on a given steel using a glass condenser for one and block tin for the other.

However, the correction for glass condensers is larger than is desirable when it is considered that the combined nitrogen found by this method in a 5-gram sample of steel lies between 0.0002 and 0.0007 gram.

Errors From Nessler Solution

A series of bessemer steels was analyzed for combined nitrogen and the ammonia determined by both the acid-alkali titration and by the Nessler colorimetric methods. Except in the case of the 0.1 per cent carbon steel, the Nessler method gave lower results than the titration method. The difference between the two values—i.e., the error in the Nessler determination—became greater the higher the carbon. Results of these analyses are shown in Table I.

TABLE I— OMPARISON OF TITRATION AND NESSLER METHODS

Bessemer Steel Samples

Approximate Per Cent Carbon	Per Cent Combined Nitrogen — Titration	Titration Average	Nessler	Nessler Average	Excess Titration Over Nessler
0.1	0.0133				
	0.0126		0.0132		
	0.0123	0.0127			
0.2	0.0105		0.0090		
	0.0107	0.0106	0.0097	0.0094	0.0012
0.4	0.0112		0.0100		
	0.0115	0.0114	0.0098	0.0099	0.0015
0.6	0.0094				
	0.0095	0.0095	0.0076		0.0019
0.8	0.0120				
	0.0117				
	0.0111				
	0.0117	0.0116	0.0093		0.0023

Many texts on the analysis of iron and steel give the Allen method with the Nessler solution, but these results indicate that in steels containing 0.2 per cent carbon or over titrimetric methods should be used.

Solution of Samples

Solution of the steel or iron is effected in a small covered beaker heated on a steam bath. A number of determinations were made in which the solution was carried out in a closed vessel and the evolved gases led through a bubble-tube containing hydrochloric acid, a procedure often recommended. Both portions of acid were then combined and the ammonia determined in the usual manner. No higher results for nitrogen were obtained than when the sample was dissolved in a beaker (Table II).

TABLE II—COMPARISON OF METHODS OF SOLUTION

Sample	Evolved Gases Not Washed in HCl. Per Cent Nitrogen	Evolved Gases Washed in HCl. Per Cent Nitrogen
Bessemer steel.....	0.0121	0.0123
	0.0125	0.0126
Electric arc weld-metal		
A- 8	0.135	0.132
A-10	0.122	0.119

Low results for nitrogen are, however, often obtained if solution is made in a beaker heated over a gas burner,

on a hot plate, or on a sand bath instead of on the steam bath as described above.

METHOD USED BY THE BUREAU[9]

It was at first thought necessary to prepare special ammonia-free hydrochloric acid for dissolving the sample, but it was later found that a fresh bottle of concentrated acid of the c.p. grade diluted with ammonia-free water to a sp.gr. 1.11 usually gave a sufficiently low blank determination. The sample of steel or iron 5 grams in weight (unless known to be very high in nitrogen[10]) is dissolved in 50 c.c. of this acid. While the solution is taking place, 30 c.c. of sodium hydroxide solution, prepared as directed by Blair and Langley,[11] one or two pieces of mossy zinc and 400 c.c. of distilled water are placed in the distilling apparatus. This distilling apparatus consists of a 1-liter Erlenmeyer flask connected with a condenser whose block-tin inner tube is bent downward at its upper end as shown in Fig. 1. The alkaline solution in the flask is then boiled until 200 c.c. has distilled over. This distillate is discarded, the contents of the distilling flask are permitted to cool slightly and the solution of the steel sample is introduced through a separatory funnel in the stopper of the distilling flask. The solution of the sample is not filtered. The beaker in which the solution of the sample took place and the separatory funnel are rinsed into the distillation flask with three 50 c.c. portions of ammonia-free water. The contents of the flask are then boiled until 200 c.c. of distillate is collected in 25 c.c. of 0.01 normal sulphuric acid. The adapter at the end of the condenser should dip into the acid or be connected with a receiver of a type which causes any escaping gas to bubble through it.

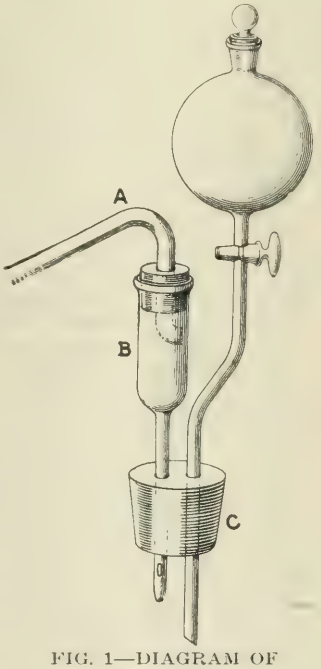

FIG. 1—DIAGRAM OF CONNECTIONS
A—Block tin tube.
B—Carbon filter funnel.
C—Flask stopper.

After distillation is complete, the excess of sulphuric acid is titrated with 0.01 normal sodium hydroxide, using as an indicator one drop of a 1 per cent aqueous solution of sodium alizarine sulphonate. The end point is the complete disappearance of the clear green color or the first indication of brown. This method of determining the ammonia in the distillate is much superior to the method involving the use of Nessler solution, and probably as convenient and accurate as the iodide-iodate method.

A review of the properties of some of the nitrides possibly present in the steel indicates that iron nitride is readily and completely decomposed by dilute acids with the formation of ammonia.[12] Aqueous acids and alkalis have little effect on silicon nitrides[13]; fusion with alkali is required to convert their nitrogen to ammonia. Manganese nitride is decomposed slowly by water and more readily by acids[14]; it is rapidly decomposed by hot caustic alkali solutions with the formation of ammonia. Aluminum nitride is completely decomposed by hot alkaline solutions.[15] Titanium nitride is insoluble in dilute acids but is decomposed in boiling potassium hydroxide solutions.[16]

Therefore, the nitrogen determined by the solution method is probably chiefly that present as iron and manganese nitrides. If the solution of the sample is not filtered before distillation, it is possible that nitrogen present as aluminum or titanium nitrides is also converted to ammonia by the boiling alkali solution during distillation. Nitrogen dissolved, adsorbed, or mechanically held in pores or blowholes will not figure in the result.

Removal of Sulphur From Illuminating Gas

The use of coals of the central coal-mining district for gas manufacture, owing to their relatively high sulphur content, makes the purification of gas for domestic and industrial uses an increasingly difficult problem. In fact, with the gradual exhaustion of the choice low-sulphur coal beds, gas purification is becoming generally more of a problem to the gas industry. Commercial hydrated oxide of iron, the commonly used purifying agent, varies widely in its quality as a gas purifier.

No completely satisfactory laboratory methods for the evaluation of oxides now exist. The Bureau of Mines is co-operating with the American Gas Association in the effort to perfect testing methods and to learn more concerning the effects of different chemical and physical conditions on the properties of hydrated iron oxide in use for gas purification. Among the conditions affecting the use of oxide studied during the present year are moisture temperature, iron content and sulphur content of oxides, and hydrogen sulphide content of the gas to be purified. A report covering the results of these studies is now in preparation.

American Fertilizers Popular in Italy

The use of chemical fertilizers in Sicily has shown a marked increase during the past few years, and American products of this class have always enjoyed a ready sale and a good reputation, according to a report to the Department of Commerce from Consul Nathan. Approximately 140,000 tons of sulphate of ammonia is consumed annually, of which 50 per cent is supplied by domestic manufacturers (north of Italy), and the remainder is imported from the United States, Great Britain and Canada.

Nearly 180,000 tons of superphosphates is used. Italian manufacturers, enjoying a large advantage in the matter of competition because of their close proximity to the sources of raw material at Tunis and Algiers, supply three-quarters of the total, and America, Belgium and Egypt supply most of the remainder.

The price of citrate of lime in Italy has been fixed for the seasons of 1922 and 1923 at 600 lire per 100 kilograms.

[9] Essentially the Allen method with modifications, chiefly those by Tschischewski (See Note 7).

[10] For alloys containing 0.1 per cent nitrogen 2-gram samples are used. With still higher nitrogen content, as in nitrogenized iron, the acid solution of the metal is diluted with ammonia-free water to a known volume and aliquot samples are taken which contain nitrogen equivalent to not more than 25 c.c. of 0.01 normal acid.

[11] A solution of 300 grams of sodium hydroxide in 500 c.c. of water is digested at 50 deg. C. for 24 hours over a zinc-copper couple.

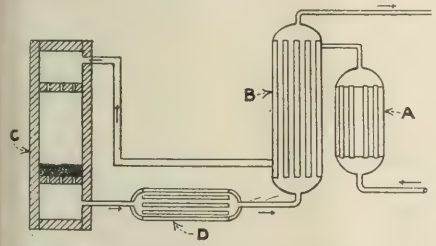
Recent Chemical & Metallurgical Patents

Production of Nitrogen Oxides From Ammonia by Catalysis—A cut is herewith reproduced, showing an apparatus in which this process is carried out. The ammonia-oxygen mixture passes through heat exchangers *A* and *B*, where the incoming gases are heated to approximately 200 deg. C. They then enter a reaction chamber of considerable size before the hot gases come in contact with the catalyst. This space is usually as much as a meter long. The contact mass in chamber *C* then oxidizes the mixture and the gases leave at a temperature approximately 750 deg. C.



They are cooled off in chamber *D* to about 400 deg. C., and then are used to heat the incoming gases in the first heat exchanger. The essential features of this process are, first, the use of the gases produced in the reaction to preheat the incoming gases, and second, the large capacity of the reaction chamber linings of the preheaters and reaction chambers are of such materials that they will not induce a premature catalytic action. Such metals as copper, iron and magnalium are avoided. The author seems to prefer non-metallic linings, such as fireclay, heavy magnesia and the like. The advantages of this apparatus are, first, the more complete oxidation, due to the elimination of inhibiting action before the catalyst is reached, and second, a very efficient use of the heat generated in the reaction. (1,426,952. Karl Bosch, of Ludmigshafen, Germany, assignor to the Badische Anilin und Soda Fabrik. Aug. 22, 1922.)

Apparatus for Washing Insoluble Powders—P. W. Prutzman, of Los Angeles, assignor to the General Petroleum Corporation of California, has developed a washer for insoluble powders which embodies the following principles: First, the powder is placed in a conical bottom tank and solvent is pumped up through the tank. Near the top of the tank is a screen, through which the solvent is permitted to go, but which in turn keeps back the particles of solid material. The solvent, after passing through the screen at the top of the tank, overflows and is pumped back into the tank again, entering at the bottom of the cone. Thus the solvent circulates upward through the powder to be washed. The solvent may be replaced by another portion of clean solvent, the old solvent being used in another similar washer on unwashed material. Finally, after successive portions of solvent have been used, the mass is dropped into a pulp tank, where it settles out. (1,426,099. Aug. 15, 1922.)

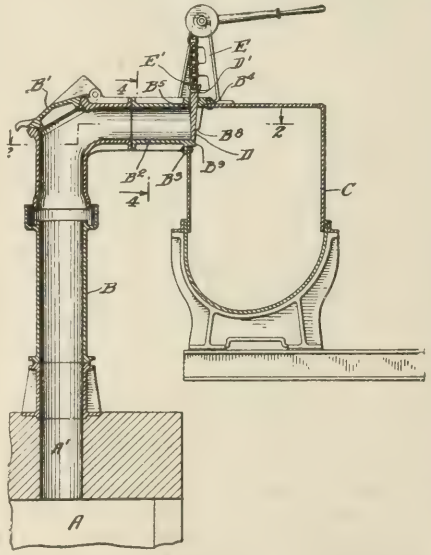
American Patents
Issued Nov. 21, 1922

The following numbers have been selected from the latest available issue of the *Official Gazette* of the United States Patent Office because they appear to have pertinent interest for *Chem. & Met.* readers. They will be studied later by *Chem. & Met.'s* staff, and those which, in our judgment, are most worthy will be published in abstract. It is recognized that we cannot always anticipate our readers' interests, and accordingly this advance list is published for the benefit of those who may not care to await our judgment and synopsis.

1,435,930—Production of Sodium Sulphate.
1,436,094—Coke Oven.
1,436,095—Coke Oven.
1,436,096—Coke Oven.
1,436,097—Coke Oven.
1,436,098—Coke Oven.
1,436,164—Titanium Pigment.
1,436,179—Production of Cyanamid.
1,436,180—Converting Cyanamid to Urea.
1,436,196—Gas Purification system.
1,436,230—Separation of Magnesia From Lime.

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Collecting Main for Coke Ovens—The invention shown in the accompanying drawing consists of a new design for a cut-off valve between an individual ascension pipe from a coke oven and a gas-collecting main serving a battery of ovens. This consists of a slide or damper valved as used on many types of ovens, but located to operate in a vertical plane instead of in a horizontal plane, as was formerly the practice. Due to the construction of this valve



and its seat, as shown in the drawing, it tends to cut away the deposits of hardened pitch and carbon which always form at this point, thus insuring the proper seating of the valve when it is hammered home. (1,433,634. Charles V. McIntire, assignor to Louis Wilputte and Alice A. Wilputte. Oct. 31, 1922.)

Improved Sulphite Pulp Process—A modified sulphite cooking liquid for which is claimed the advantages of producing a finer fiber and one which is capable of being easily bleached and easily hydrated and from which the waste liquor can be easily recovered is described in a specification taken out by George A. Richter, of Berlin, N. H., and assigned to the Brown Co. A cooking liquor is prepared by passing gaseous sulphur dioxide through a 3 to 5 per cent solution of sodium sulphate until the resulting acid solution contains free sulphurous acid from 2 to 7 per cent. The sodium sulphate is reduced by this treatment to sodium sulphite and sulphuric acid is formed. The inventor assumes that as the cooking progresses sodium sulphite is used up in neutralizing free organic acids formed by the hydrolysis of the cellulose. This unbalances the reversible reaction and brings about the formation of more sodium sulphite, which is in turn able to react with more free organic acids. Thus progressive decomposition continues until the cooking operation is complete. In this way the sodium sulphate present in solution acts as an available source of sodium, which may be transformed into an active constituent represented by sodium sulphite. Experience has demonstrated that the concentration of sulphuric acid resulting from this progressive supply of sodium sulphite is not sufficient to injure the cellulose fiber resulting from the cooking process.

The waste liquor from the process is collected in a suitable tank and is neutralized with sodium carbonate and is then evaporated and concentrated and then burned in an oxidizing atmosphere so that the sulphate is recovered in the same form in which it was previously used and is thus ready to be used again.

The advantages claimed for the process are that it is possible to produce a cooking liquor by passing the sulphur dioxide through a clear solution rather than through a milky suspension, thereby eliminating the trouble encountered in handling such suspensions; its advantage over calcium bisulphite liquor lies in the fact that any sulphate formed by the action of sulphur trioxide in the burner gas will not produce insoluble calcium sulphate. It is also claimed that the process produces a pulp of better color and greater strength than the average unbleached pulp by the calcium bisulphite process. The ease of recovery of the sulphate from the waste liquor is of course an added advantage. (1,427,125. Aug. 29, 1922.)

Desulphurizing Gas—A process which consists in first passing the gas through charcoal, then adding to it at least the required amount of oxygen for oxidizing the hydrogen sulphide and passing the mixture through active charcoal is patented by Alwin Mittasch and Max Schumann, of Badische Anilin und Soda Fabrik. (1,430,920. Oct. 3, 1922.)

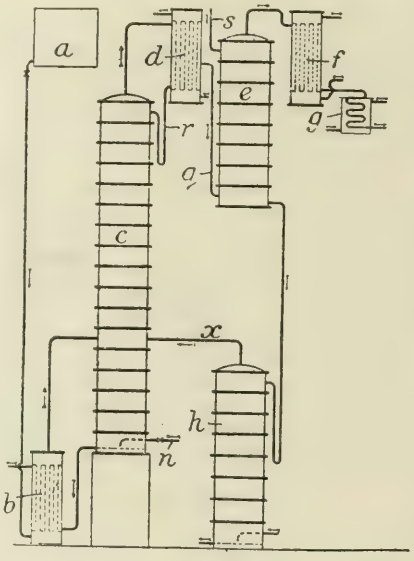
Complete Gasification Apparatus—Sir Arthur McDougall Duckham in this patent describes a complete gasification process which consists in a combined vertical retort and water-gas machine. Several of the retorts are superimposed on a single water-gas generator so that the coke is discharged directly from the retorts into the water-gas generating space. The retort is heated externally during the blow period by the blast gases and during the gas-making period by burning a small portion of the water gas in the heating flues around the retort. The remainder of the water gas made passes through the coal which is being coked, also contributing to the heat for carbonization. (1,428,421. Arthur McDougall Duckham, London, England. Sept. 5, 1922.)

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Inks and Paints—Inks and other pigmenting and like compositions for printing, duplicating, etc., comprise as the vehicle for the coloring matter an emulsion or emulsoid in the form of a plastic solid, of which the yield value (defined as the finite pressure it is necessary to apply before any flow through a capillary orifice takes place) is materially greater for the emulsion than for its components, the yield value of the components being, for example, zero. The composition may have the property of breaking down when brought into contact with paper or other porous material, one of the components being absorbed thereby. One of the components may be an oleaginous material, such as Yorkshire grease, wool fat, wool wax or adeps lanæ, a wax such as Japan wax or beeswax, or a soap insoluble in water, and the other component may be water, the components being emulsified with or without the use of emulsifying agents. The water forms the internal phase, and preferably acts as the sole solvent for the coloring material, which must be of such a nature as not to break down the emulsion or reverse the relationship of the phases. Pigments such as graphite, which are selectively wetted by the external phase, may also be used. The oleaginous material may be mixed with a thinning agent. A thickening agent such as gum or starch may be dissolved in the water, but the addition of a substance to delay evaporation is unnecessary. A salt of a polyvalent metal may also be added. Three examples are given, as follows: (1) Yorkshire grease is dissolved in a light mineral oil and the solution incorporated with a 10 per cent solution of nigrosine in water; (2) aluminum stearate is treated with a light mineral oil and emulsified with a 5 per cent solution of nigrosine in water; (3) a mixture of turkey red oil, glycerine, and castor oil, with a pigment such as graphite, lamp-black or hydrated alumina, is emulsified with water. (Br. Pat. 183,513. A. de Waele, London. Sept. 20, 1922.)

Dehydrating Alcohol—In preparing alcohol of 98 to 99 per cent strength, alcohol vapors are brought into contact with glycerine, which acts as a dehydrating agent. The glycerine preferably flows down a rectifying column up which alcohol vapors are passed. In a continuous apparatus, alcohol of 92 to 93 per cent strength passes from a tank *a* through a preheater *b* to a column *c* heated by steam injected through a pipe *n*. The vapors from the top of the column are partly condensed in a condenser *d*, the liquid condensate from which is returned by a pipe *r* to the column *c*. The uncondensed vapors pass by a pipe *q* to the base of a column *e*, down which glycerine admitted by a pipe *s* passes. The vapors pass from the top of the column to condensers *f*, *g*. Glycerine passes from the base of the column *e* to a column *h*, in which it is treated



with steam to remove alcohol, which is passed as vapor by a pipe *x* to the column *c*. The glycerine is finally treated to separate water and used again. A second specification, 184,129, covers the use of an anhydrous or hygroscopic salt such as calcium chloride, zinc chloride or potassium carbonate as the dehydrating agent. (Br. Pat. 184,036. J. van Ruymbeke, Marseilles, Sept. 27, 1922.)

Fatty Acid Esters—Organic acids, other than polyoxy fatty acids, are converted into esters by the aid of zinc, tin or other metal of the periodic group of which tin is a member. Particular reference is made to the esterification of fatty and resin acids. Fats containing free fatty acids can be neutralized by heating at ordinary or reduced pressure in the presence of tin with the necessary quantity of glycerol or of the mono- or di-glycerides of such acids as caprylic, lauric, myristic, stearic, oleic or erucic acid. According to the example, a mixture of copra oil waste and copra fat acids is heated with glycerine in the presence of tin until the acid value of the fats becomes practically nil, the reaction taking place with exclusion of air first at normal pressure and then under reduced pressure. (Br. Pat. 183,897. P. Haddan, London. Sept. 27, 1922.)

Viscose—To avoid the necessity for the ripening process in the manufacture of viscose and to obtain directly a high molecular product, cellulose, or a near conversion product of cellulose, associated with caustic alkali in a concentration of 15 per cent and upward, preferably 20 to 50 per cent, and in a quantity of not more than two molecules of caustic alkali, preferably one molecule or less, per molecule of cellulose, is treated with carbon bisulphide in a quantity of not more than one-half molecule—for example, one-fifth to one-half molecule—per molecule of cellulose. The treatment with the reduced proportion of carbon bisulphide is conveniently carried out in the presence of benzol or other solvent or diluent for carbon bisulphide. In an example, cellulose is treated with a 20 to 50 per cent caustic soda solution, and the surplus liquid separated so as to leave one molecule of caustic soda to one molecule of cellulose; either immediately or after standing, one-half to one-quarter molecule of carbon bisulphide diluted with benzol is added, and the mixture kneaded; the diluent is eventually separated by evaporation *in vacuo* or by the addition of water. The viscose is soluble in water or in alkali, and may be spun without ripening. When used for the spinning of artificial silk or in the manufacture of films, etc., the following coagulating baths may be employed—bisulphates or mineral acids, or weaker acids such as acetic or formic acids, or stronger acids such as oxalic acid alone or together with such weaker acids, or alkali bicarbonates; in the case of these weaker acids or alkali bicarbonate baths, the temperature of these is preferably raised to 30 to 40 deg. C. (Br. Pat. 183,882. H. Dreyfus, London. Sept. 27, 1922.)

Tungsten—Tungsten powder suitable for the production of lamp filaments is obtained by reducing (in hydrogen) materials called "complex tungstic acid." The materials mentioned are compounds of tungstic acid with silicic and boric acid respectively and are prepared by boiling sodium tungstate with water glass and acetic acid or with silicic acid or boiling tungstic acid and ammonia with silicic acid; or by boiling sodium tungstate with boric acid. In each case the treatment is continued until strong hydrochloric acid does not precipitate tungstic acid. The reaction mixture is in some cases poured into strong hydrochloric acid and an oily layer is separated from which the complex tungsten acid is crystallized. Specification 155,851 is referred to. (Br. Pat. 183,816; not yet accepted. Naamlooze Vennootschap Philips' Gloeilampenfabrieken, Eindhoven, Holland. Sept. 20, 1922.)

Synopsis of Recent Chemical & Metallurgical Literature

Investigation of Soil Absorption

As a rule, considerably less than 5 per cent of the absorptive capacity of a soil is in the unaltered mineral particles, and 95 per cent or more is due to what is known as the colloidal material, says the U. S. Department of Agriculture in a professional paper, "Absorption by Colloidal and Non-collodial Soil Constituents," recently published as Department Bulletin 1,122.

The results given in the bulletin are at variance with some of the older but still prevalent conceptions regarding soil absorption. According to the old notion, the more highly absorptive soils were supposed to contain some specially absorptive mineral called zeolites, but it is now very generally recognized that if definite crystalline zeolites are present at all they are there in extremely small amounts. It was also thought that aside from the absorption caused by organic matter, most of the absorptive capacity was due to the fineness of the mineral particles, and not to the relative amount of surface exposed by these particles. It is now coming to be realized that the highly absorptive inorganic material is not crystalline zeolites but amorphous material such as iron hydroxide, aluminum hydroxide, silicic acid and aluminum silicate gels. The investigations tend to confirm the more modern view of soil absorption and give for the first time an estimate of the amount of absorption due to the colloidal material and to the non-colloidal particles.

Ethyl Chloride in Refrigeration

That ethyl chloride is a very convenient material for commercial refrigeration is the conclusion one draws from a paper by Prof. C. F. Jenkin recently presented before the British Coal Storage and Ice Association. Commenting on this paper in its issue of Oct. 21, 1922, *The Chemical Age* (London) lists the various advantages of ethyl chloride, among which are the following:

It did not attack metals, but it did contaminate mercury. It attacked india rubber, but vulcanized rubber tubing and corks could be used, though they leaked a little. They swelled considerably, but returned to their original size when the ethyl chloride dried off. Pure rubber tape was softened almost to solution. Vulcanite swelled moderately. It caused most woods to swell, but lignum vitæ could be used for valves, etc., when a non-conductor of heat was required. Bakelite was also useful as a non-conductor; it swelled only very slightly.

Liquid ethyl chloride dissolved a small quantity of water, but could be dried by passing it through calcium chloride drying tubes. With water it formed very remarkable ice crystals. Similar crystals formed at the throttle valve in a refrigerating machine if there was any water dissolved in the ethyl chloride, and quickly choked the valve. Ethyl chloride was also a convenient cooling material for use in laboratories; when sprayed on to any object, the temperature is quickly reduced to —20 deg. C. or lower.

For mechanical refrigeration ethyl chloride was very suitable. The vapor compression cycle was the one used. The pressures corresponding to the ranges of temperature commonly required were very low—for example, for a range of ±20 deg. C., the pressures were 19.4 and 3.5 lb. per sq.in. absolute. The type of compressor generally used was a rotary pump. To avoid air leaks all valve spindles, compressor shafts, etc., had to be sealed with glycerine, so that any leakage was of glycerine.

The flammability of ethyl chloride was its most serious drawback. To get over this, various "non-flam ethyl chlorides" had been put on the market in Great Britain. These were mixtures of ethyl chloride with large proportions of ethyl bromide. The mixture was not only non-flammable but could be used as a fire extinguisher. Its properties as a refrigerator were not very different from those of ethyl chloride, but as it was heavier than glycerine special separators were necessary.

Book Reviews

JOURNAL OF THE IRON AND STEEL INSTITUTE, 1922, No. 1. (Volume No. 105). Edited by *George C. Lloyd*, Secretary. Published by the Institute, 28 Victoria St., London, S. W. 1, England. (American Agents: Spon & Chamberlain, 123 Liberty St., N. Y. City.) Price, $9.50.

A great variety of papers is contained in this, as in all recent volumes of the *Journal* of the British Iron and Steel Institute, ranging from the operation of a blast furnace to X-ray studies of crystal structure. Perhaps half the volume could be classed as "practical," the other half as "theoretical."

Blast-furnace practice was discussed in its broad commercial aspects by the president, Francis Samuelson, in his address. D. E. Roberts also presented details of various methods of getting ore, coke and flux from the stockyard to the top of the blast-furnace shaft in a paper entitled "Notes on Blast-Furnace Filling." Another voluminous paper, "Recent Developments in Power Production," excited a deal of discussion, as did also a study of "British Siemens Furnace Practice," by Fred Clemens. The latter comprised a thorough analysis of the operations of a new 60-ton open-hearth furnace; all the observed data are included on log sheets, and the derived conclusions should undoubtedly be studied by all furnace superintendents and designers.

Reactions between gases and the constituents of steel are discussed in three papers by Carpenter and Elam, Austin, and Ehn. The latter restated his views on the influence of dissolved oxides on carburizing and hardening qualities of steel. Several members, while admitting that Ehn had discovered a connection between microstructure and defective carburizing properties, doubted that he had proved trat the trouble was due to dissolved oxides. On the other hand, Portevin was able to duplicate Ehn's "abnormal structures" when carburizing overblown bessemer steel.

Microscopical and thermal studies of austenite and its decomposition products were presented by Hallimond, Honda and Kikuta, Yamada, Belaiew and Whiteley—forming in all a mass of extremely interesting metallographical data on hardened and annealed steel. Westgren and Phragmén also presented a contribution on "X-Ray Studies on the Crystal Structure of Steel." In view of the opinion Dr. Westgren presented in *Chem. & Met.*, vol. 25, p. 641, when discussing the "Slip Interference Theory of Hardening," it is interesting to observe that he now presents evidence to show that martensite has the crystallographic structure expected of extremely minute crystals of alpha iron. He thinks these crystals are of the order of 20 A.u. in diameter, containing only a few hundred atoms, and are on the verge of being totally amorphous. Furthermore, the cubic lattice of both gamma and alpha iron is slightly distended by the carbon in austenite and martensite in a way to suggest that carbon is uniformly distributed as atoms in both constituents. Cementite has also been found to crystallize in the orthorhombic system.

About 150 pages at the end of the book are devoted to notes on current literature. Perhaps 750 references are noted—many of them of course are quite perfunctory, but on the other hand, excellent digests of many important papers can be noted on even a hurried examination. E. E. THUM.

A HANDBOOK FOR ELECTROTYPERS. By *John F. Locke*. 35 pp. Published by the author, Cincinnati, 1922. Price, $1.

The introduction states that this booklet served as a basis for a series of lectures to electrotypers. There is today a large field for the application of the principles of science in both the electroplating and electrotyping industries, and the author is to be commended for his efforts in this direction. It is unfortunate, however, that, perhaps through the desire for simplification, he has made several misleading or inaccurate statements, such as the following: "The internal resistance [of a bath] is reduced by . . . a lowering of the temperature." "The higher its conductivity [of an acid copper bath] the lower the *amount of current* needed." "Boric acid is being used [in a nickel solution] to increase the conductivity of the bath." The presence of these and other errors reduces greatly the value of the book to those who are in need of an accurate presentation of scientific facts and theories in simple language.

War Department Appoints Chemical Advisory Board

Asks Co-operation of Prominent Representatives of Industry as Aid in Carrying Out National Defense Act

The Assistant Secretary of War, J. M. Wainwright, has addressed a letter to twenty-two prominent representatives of the chemical industry and of technical educational institutions requesting their individual co-operation in an advisory capacity in matters pertaining to the chemical industry which present problems difficult of solution by the layman. The letter points out the desirability of co-operation between the War Department and the industrial interests of the country in preparing for the future defense needs of the nation in carrying out the provisions of the national defense act.

Desirability of Co-operation

The letter is reproduced below:

In carrying out the provisions of the national defense act, with respect to the question of preparation for mobilization of national industries in time of war, I very often find myself confronted with matters regarding the broad field of chemical industry difficult of solution by laymen.

I have conceived the idea of asking fifteen or twenty gentlemen connected with the various activities of the chemical field (industrial, academic and research) to co-operate with me in such matters, assuming that they ought to know what the War Department is doing, or would be interested to the extent of assisting in an advisory capacity.

You, of course, will realize that in carrying out the provisions of the national defense act in the way of preparation for the future defense needs of the nation, there should be co-operation between the War Department and the industrial interests of the country, and I trust that you may see your way clear to permit me to call upon you for advice when the occasion demands.

The representatives of the industries, educational institutions, associations and publications who have been asked to serve on the advisory committee are as follows:

Prominent Men on Advisory Committee

Edgar F. Smith, president American Chemical Society; Henry Howard, vice-president of the Grasselli Chemical Co.; Edward W. Washburn, chairman, division of chemistry and chemical technology of the National Research Council; R. A. Milliken, research professor of physics, California Institute of Technology; V. C. Vaughan, National Research Council; Julius Stieglitz, professor of chemistry, University of Chicago; S. W. Wilder, Synthetic Organic Chemical Manufacturers' Association; C. L. Reese, chemical director, E. I. du Pont de Nemours & Co.; C. P. Townsend, Union Carbide & Carbon Corporation; J. George Lehman, vice-president, Bethlehem Foundry & Machine Co.; H. N. Ott, president, Spencer Lens Co.; John E. Teeple, consulting chemist; M. C. Whitaker, vice-president, U. S. Industrial Alcohol Co.; H. C. Parmelee, editor, *Chem. & Met.;* C. S. Miner, consulting chemist; Charles H. Herty, president, Synthetic Organic Chemical Manufacturers' Association; A. B. Lamb, professor of chemistry, Harvard University; Charles A. Meade, E. I. du Pont de Nemours & Co.; F. G. Cottrell, Nitrogen Research Laboratory; Charles L. Parsons, secretary, American Chemical Society; H. E. Howe, editor, *Journal of Industrial & Engineering Chemistry;* R. B. Moore, chief chemist, U. S. Bureau of Mines.

Engineering Council to Consider Important National Problems

A number of important problems of national as well as technical interest will be considered by the American Engineering Council, the executive body of the Federated American Engineering Societies, at its meetings in Washington, Jan. 11 and 12, 1923. The 12-hour day in industry, topographic mapping, government reorganization, types of government contracts and a wide range of other engineering, political and economic topics will be discussed. The plan for an engineering investigation into the Muscle Shoals situation will also receive consideration.

Tear Gas Effective for Dispelling Mobs

A highly effective method of spraying tear gas has been developed by the Chemical Warfare Service. The new device recently was tried out before police officials in Washington and was so effective that the observers, supposedly at a safe distance, inadvertently went through the experience of receiving a very thorough application of the gas. The representatives of the Police Department are very ready to testify as to its effectiveness in controlling mobs or rioters.

Sugar Refiners Protest Tariff Rate

Extensive Investigations Will Be Necessary to Bring Tariff Commission Data Up to Date

Acting under the flexible section of the new tariff act, an application for a reduction in the duty on sugar has been filed with the Tariff Commission in the name of the United States Sugar Association, an organization said to include in its membership a number of independent refiners in this country who have interests in Cuba. Cuban sugar interests are raising a fund of $70,000 to assist the effort to reduce the duty.

The application was filed by Edward Schoenech, of the law firm of Bond, Schoenech & King of Syracuse, N. Y., as attorneys for the United States Sugar Association, of which H. S. Rubino, of New York, is executive chairman and counsel.

While no specific reduction is asked, the application is understood to set forth that the duty fixed by the new tariff act is fully 1 cent per pound more than is necessary to equalize the differences in costs of production of sugar in the United States and Cuba. The flexible tariff section authorizes the President, after investigation by the Tariff Commission, to change rates of duty not more than 50 per cent to equalize costs of production.

The sugar duty in the new tariff is 2.20 cents per pound, and as Cuba enjoys a 20 per cent preferential on imports into the United States, the effective duty on Cuban sugar is 1.76 cents per pound. Under the emergency tariff, which the 1922 tariff act supplanted, the general duty on sugar was 2 cents per pound, with 1.60 cents per pound on Cuban sugar.

Investigations Necessary

As the data of the Tariff Commission regarding sugar are out of date, considerable preliminary investigation will be necessary before this application is reported to it for action. It probably will be necessary to send an agent to Cuba, and possibly elsewhere abroad, before a report can be compiled. It is not probable that there will be any definite action regarding this petition for several months, and even then the commission might decide that there had been no change in conditions since enactment of the tariff bill with its rates expressing the will of Congress which would justify an investigation.

Students Keep Busy During Vacation

Chemical Engineering Students at University of Michigan Establish Record for Industry During Summer

Statistics compiled by the department of chemical engineering at the University of Michigan show that the policy of encouraging undergraduates to obtain summer employment is approved by the students. Tabulations representing a digest of the survey of summer employment of the present junior and senior classes of chemical engineers at the university show that outside of those who attended summer school, 94 per cent obtained employment of some nature. Of the eighty men who obtained employment, 11 per cent worked in industrial laboratories, 35 per cent engaged in plant work outside of the laboratories, and the remainder obtained employment of a miscellaneous nature.

The university points to this record with pride, as proving a spirit of industry and earnestness on the part of the students and indicating that a great majority of them are paying at least a portion of their college expenses. It is also interesting to note that there appears to be no difficulty for a student to obtain useful employment during the summer months.

Variety of Occupations

A great variety of occupations are represented by the report of the seniors, ranging from specialized engineering work in chemical plants to common laborers and railroad ticket agents. Among the different types of laboratories represented in the report are highway laboratories, dye works laboratories, locomotive works laboratories and automobile plant laboratories. The industries which furnished employment to the students include gas plants, automobile plants, food product plants, metallurgical plants, foundries, telephone companies, alkali plants, condensed milk plants, boiler plants and oil companies.

Not only does this report speak well for the co-operative spirit of the undergraduate but it shows that such efforts by educational institutions will have the support of industrial establishments. Among the names of the companies co-operating to the extent of giving summer employment to these undergraduates are dozens of well-known manufacturers of highly specialized technical products.

Seek Substitute for Carbon Bisulphide as Grain Fumigant

The use of carbon bisulphide as a fumigant of grain has been discontinued by the railroads of the country, except at certain points, particularly Baltimore and New Orleans. The Department of Agriculture is working on a series of tests looking to the development of a more suitable fumigant for grain.

May Distribute Byproduct Gas for Industrial Fuel

The proposed developments by the Alabama Byproducts Co., operating a large coking plant near Birmingham, to lay a pipe line through which byproduct gas could be transported to a number of industrial plants in the eastern section of the city is being watched with interest by the other operators of similar plants in the district. The city commission of Birmingham has been requested to grant a permit for the construction of this pipe line, and it is thought it will grant the request as soon as it has made an investigation.

Every byproduct plant in the Birmingham district is located near an active industrial section. Should the Alabama Byproducts Co. be permitted to lay the gas main to serve industrial plants, it would establish a precedent and make the path clear for the other companies to do likewise.

It is proposed to lay a 12-in. main from the plant to the East Birmingham section, a distance of about 2 miles, along the streets of Birmingham and the roads of Jefferson County. The gas is to be furnished to the Stockham Pipe & Fittings Co. and several other industries. The gas will not be purified and will not be connected with the mains of the Birmingham Railway, Light & Power Co., which takes gas from the Sloss-Sheffield Co. for public service distribution.

Morris W. Bush, president of the company, stated that the gas would be furnished to industrial plants only, and would be furnished them only when a surplus is available.

Progress Made in Reduction of Varieties of Fertilizers

Meetings of fertilizer salesmen with the state agronomists to agree on a policy of pushing a reduced number of high-analysis grades of mixed fertilizers are being arranged in the five states which recently reached an agreement with manufacturers of the Middle West to reduce from fifty-seven to fifteen the analyses being offered for sale in those sections.

Each state, through its authorized soils representatives, is selecting from the list of fifteen the special high-analysis fertilizers best suited to the varying conditions within its own borders. Ohio has selected twelve and Missouri ten. The selection will be explained to the salesmen, with the uses for which each analysis is best suited. The meeting in Ohio has been held, and those in Indiana, Minnesota, Michigan and Missouri, the other states represented in the agreement, will be held soon.

The soil improvement committee of the National Fertilizer Association is preparing stickers and other forms of advertising to make known the selected list for each state, giving the analyses selected by the college station of each state with the proper use for each major crop.

To Investigate Scarcity of White Arsenic

Cotton-Belt Congressmen Ask Action to Insure Farmers Supply of Insecticide

Aroused by complaints of constituents that the price of calcium arsenate has advanced rapidly and that the supply is short at any price, members of Congress from the cotton belt, where the compound has proved to be the most effective insecticide for combating the ravages of the boll weevil, are attempting to launch an investigation.

Two Resolutions Presented

Senator Harris of Georgia has written both the Department of Justice and the Federal Trade Commission asking them to investigate whether there exists a combination to control the price of white arsenic, the base of the insecticide. Representative Wise of the same state has introduced a resolution in the House directing the Federal Trade Commission to report the cost of manufacturing and producing calcium arsenate and whether the production and prices are controlled by any unlawful combination. Senator Smith of South Carolina has drawn a Senate resolution declaring that a crisis exists for agriculture because of the difficulty of obtaining arsenical insecticides and directing the Department of Agriculture, through the Bureau of Entomology, and the Department of the Interior, through the Geological Survey, to investigate the supply of white arsenic and possible development of new sources of supply.

The Secretary of Agriculture has reported informally that the production of white arsenic in the United States last year was below normal and that reports indicate that Australia has contracted for much of the Canadian supply.

There is no tariff duty on white arsenic, this chemical having been continued on the free list at the insistence of Southern Senators.

Georgia Buys Arsenic

The State of Georgia has taken the matter of combating the boll weevil in its own hands and has taken steps to obtain such supplies of calcium arsenate as may be necessary to cover the cotton acreage of the state in the coming season. Negotiations are under way between the Georgia State Department of Agriculture and the Salt Lake Insecticide Co. for these supplies. It is said that the state is planning to take the entire output of this company on contract during the coming season.

Some authorities have been counting on this new production to prevent an extremely high price for calcium arsenate in the spring, but if the entire production is taken out of the market by the State of Georgia alone, there is little chance that prices of calcium arsenate will be depressed to any extent by this production.

Management Problems Before Taylor Society

Papers on Application of Scientific Control to Various Industries Are Read at the Annual Fall Meeting

On Nov. 23 and 24 the Taylor Society held its annual fall meeting in the rooms of the Federated American Engineering Societies, New York City.

The annual business meeting was held on Nov. 22, in connection with an informal dinner at the Café Boulevard. In addition to the election of officers, plans were outlined at this meeting for the work of the society during the ensuing year, including the promotion of the use of budgets for control of sales and production.

The technical meetings occupied two daily and one evening session on Nov. 23 and 24. These meetings covered very thoroughly the application of scientific management and control to various industries, showing how the industry should be organized, how the data should be obtained and how the budgets made up from these data could be applied to effective operation of the industry. Examples were drawn from effective industries such as the Corona Typewriter Co., the Lewis Manufacturing Co., the Joseph & Feiss Co., Day & Zimmerman, Inc., the Hood Rubber Co., the Dennison Manufacturing Co., the United States Rubber Co., the Union Carbide Co., and the Tidewater Oil Co.

The following topics were covered in developing the scheme of the program: The organization and the management of a medium sized plant; statistical compilation and its uses; shaping management to meet developing industrial conditions; master budgets of sales and production; reduction of waste, and the supervision of personnel.

Sales Problem of the Future

The paper on "Shaping Management to Meet Developing Industrial Conditions," given by H. S. Person, managing director of the Taylor Society, was particularly noteworthy. Mr. Person pointed out that the market before industry today and probably for the next decade is a buyers' market. Under this condition the sales problem will be the most critical problem which industry must meet. In the solution of this problem two important phases will stand out: First, the market must be thoroughly analyzed and second, precise co-ordinated schedules of sales, production and finance must be made on the basis of this analysis. After these two phases of the problem have been satisfied, the most complete co-operation within the organization will permit successful operation.

To Study U. S. Potash Plants

The Bureau of Mines has assigned Dr. Andrew Stewart to the work of making a survey of the present conditions of the 88 potash permits outstanding. Dr. Stewart has been studying potash production in this country and its possibilities.

Expect Bill to Authorize Crediting of Reparation Dyes to Army Expense

A joint resolution will be presented in Congress in the near future authorizing acceptance of German dyes and chemicals from the Reparations Commission to be charged against the bill of the United States for maintaining troops on the Rhine, and setting up an agency to distribute these products, according to report in Washington.

The resolution probably will limit the quantity which may be accepted for this purpose and also throw further limitations about the action which will protect domestic producers of chemicals and dyestuffs.

The State Department has retained F. S. Dickson, who was chief of the Dye and Chemical Control Board established to operate the dye licensing system, or embargo, as its adviser in handling this question of reparation dyes.

Dye Strength Regulations

The Treasury Department has under advisement the issuance of temporary regulations for the importation of coal-tar products pending determination of questions of comparability and standard strengths toward which a board is now working. Dye importers have pointed out that until these questions are determined there is danger of confiscation under the new tariff act through erroneous declarations of value and have urged that temporary arrangements be made.

The State Department is considering three plans for the handling of reparation dyes. Each of the plans under consideration contemplates the formation of a board or a commission to be representative of manufacturers, importers and consumers of dyes.

One of the plans contemplates the setting up of this board as a part of the State Department to distribute the dyes. Another would make the board, or commission, independent of the State Department, to which the department would assign its equity in these dyes. Still another plan is that the State Department sell outright to the board, or commission, the dyes allotted to this country.

It is believed that one of these plans will be used as a basis for a draft of a joint resolution which will be submitted to Congress as soon as the necessary consideration has been given the proposals.

Washington and Baltimore Chemists Visit Sugar Refinery

On Nov. 24 about forty Washington chemists joined an equal number from Baltimore and visited the Baltimore plant of the American Sugar Refining Co. This largest and most up-to-date sugar refinery of the world was explained in detail by special guides. At a meeting the same evening an address on the economics and the engineering problems of sugar refining was given by C. L. Huettinger, superintendent and chief engineer of the plant.

Nobel Chemistry Prizes for Soddy and Aston

Two British Physical Chemists Awarded Prizes for Most Important Work in Chemistry During 1921 and 1922

The Nobel chemical prizes for 1921 and 1922 have been awarded to Prof. Frederick Soddy of Oxford, and Dr. F. W. Aston of Trinity College, Cambridge. The Nobel prizes, which are probably the best-known honorary awards for scientific achievements, were founded by A. B. Nobel, the Swedish inventor of dynamite, for the encouragement of men and women who work for the interests of humanity. They are awarded annually for the most important work during the year in physics, chemistry, medicine, physiology, idealistic literature and service in the interest of peace. The prizes average $40,000 each.

Professor Soddy's Activities

Curiously enough, the two recipients were born within a day of each other, Dr. Aston on Sept. 1, 1877, and Professor Soddy on Sept. 2 of the same year, and both have studied under Sir Ernest Rutherford. Professor Soddy, whose name is particularly associated with the study of radio-activity, was educated at Eastbourne College, University College of Wales, and Merton, Oxford. In 1900 he was appointed demonstrator in chemistry at McGill University, Montreal. He was appointed lecturer in physical chemistry and radio-activity at the University of Glasgow in 1904, a post which he retained until 1913, when he left to take up the professorship of chemistry at Aberdeen University. In 1919 he was appointed Lee's professor of inorganic and physical chemistry at Oxford. Among his other distinctions, Professor Soddy has been president of the Röntgen Society and was the recipient of the Cannizzaro prize (Rome) in 1913. He was made a foreign member of the Swedish Academy of Sciences in 1919. He is the author of numerous scientific publications, chiefly on radio-activity, some of his works being "The Interpretation of Radium," "Chemistry of the Radio-Elements," and "Science and Life."

Aston Holds Many Honors

Dr. Francis William Aston's work on electric discharge in gases, mass spectra, isotopes and other physical and chemical subjects is well known. He was educated at Malvern College, Mason College, Birmingham University and Cambridge University. In 1909 he was appointed assistant lecturer in physics at Birmingham University. The following year he entered Trinity College, Cambridge, and studied under Sir J. J. Thomson and Sir Ernest Rutherford at the Cavendish Laboratory. He was awarded the MacKenzie Davidson medal of the Röntgen Society in 1920, and has been secretary of the Cambridge Philosophical Society since 1920. He was recently elected a Fellow of the Royal Society.

Manufacturers Collect Data on Refractory Brick

Questionnaires to Be Sent to All Users of Refractory Brick to Summarize Properties Demanded in Practice

An industrial survey which has for its purpose the uncovering of a mass of information with regard to the furnace conditions which refractory brick must meet in actual service will be conducted by the Refractories Manufacturers' Association in co-operation with committees which have already been appointed in associations of users of refractory brick and with individuals, firms and corporations to whom refractory brick is an industrial necessity. Up to the present, research in refractories, particularly in connection with the manufacture of refractory brick, has been largely confined to laboratory work.

This survey will consume the better part of 2 years and it is hoped that preliminary reports will be made at the end of the first 3 months, the first half year and so on, until the survey is completed. These reports will cover the information which will be gathered by using a rather elaborate questionnaire which will be distributed to consumers of refractory brick in the thirteen industries to which the bulk of this material goes. These include blast furnaces, stoves and connections; open-hearth furnaces and metal mixers; heating, puddling and forge furnaces; cupolas; malleable furnaces; oil refineries; gas plants; glass houses; by-product coke ovens; zinc, copper and lead refineries; boilers; cement, lime and plaster kilns, and kilns for burning ceramic products.

The questionnaire covers temperature and combustion conditions found in the typical furnace, abrasion, slag action, the presence or absence of uncommon furnace gases, spalling conditions, loads, insulation, character of draft, etc. This information will be sought in the industries named and the answers to the questionnaires will be sent to the Mellon Institute of Industrial Research, at Pittsburgh.

When enough information has been received to warrant the issue of a progress report in any single industry, this report will at once be made; it will include a statement of the more general and possibly typical conditions, with data relative to conditions which would properly be considered exceptional in that industry. Meager as these progress reports may be, they will be an important addition to present knowledge.

Conditions Rapidly Changing

Attention has been called to the rapidly changing conditions in many industries, caused by the necessity of obtaining greater production from each unit. To meet these conditions, brick of entirely different characteristics have been developed. In a great many cases no attempt has been made to co-ordinate the changes in requirements with the changes in the refractory material. This has resulted, in many cases, in the use of refractories which, while seemingly well suited for the purpose, did not and could not live up to their reputation. A study of furnace conditions often develops the cause of the trouble; so it is thought that a similar study will develop these conditions in advance of expensive failures.

Every consumer of refractory brick will derive a certain benefit from the successful prosecution of the work described. Wastes will be eliminated, which cannot help but reduce production costs. Intelligent service will follow authentic knowledge of requirements. The whole movement augurs well for the industry which is launching it and for every industry which finds refractory brick a necessary part of its plant equipment.

War Department Offers Sodium Nitrate for Sale

The War Department has called for bids on 25,000 tons of sodium nitrate, stored at Jacksonville, Tenn. Sealed bids will be received at the New York office of the Ordnance Salvage Board, Army Building, 39 Whitehall St., New York, until noon, Dec. 15. The material is offered in lots of 100 tons or more. It is packed in bags.

Week of Practical Instruction in Water Purification Planned in Texas

Arrangements are being completed for a short course of practical instruction for water and filtration plant operators at Dallas, Tex., during the week of Jan. 15, at which time the opening of the new White Rock filtration plant will be celebrated. The course will be under the joint direction of the State Health Department and the Dallas Health Bureau. Such subjects as storing, purification and distribution of water will be discussed by authorities on the topics during the course, and one day will be given over to a complete inspection of the White Rock plant. W. T. Davidson, director of public health, Dallas, will preside at the different sessions. The speakers will include Helman Rosenthal, chemist in charge of the Turtle Creek filtration plant; Robert T. Hill, geologist; C. M. Adams, city chemist and sanitarian; Major W. J. Powell, engineer to the supervisor of public utilities; John W. Everman, supervisor of public utilities; and David Morey, engineer in charge of construction of the White Rock filtration plant.

Personal

H. L. Blackmer has been elected chairman of the board of the Midwest Refining Co., Denver, Colo., manufacturers of refined petroleum products. T. A. Dines, senior vice-president, has been elected president.

Eversley Childs, formerly head of The Barrett Co., has resigned from the Allied Chemical & Dye Corporation and has been succeeded by Charles Robinson Smith, who was long an attorney for and vice-president of the General Chemical Co. Clinton S. Lutgens has been made vice-president of the corporation. Mr. Casey, formerly of the General Chemical office staff, has been made treasurer and Mr. Crisp has been made secretary. J. M. Weiss and C. R. Downs, lately honored by the Franklin Institute for their achievements in research, more particularly for the catalytic oxidation of benzene, and long connected with The Barrett Co., have also resigned.

Albert A. Heimrod, formerly with the Research Corporation, has been appointed chief engineer for the Federal Phosphorus Co. and other Swann interests in Alabama.

P. M. McHugh, of the Dorr Co., has gone to Hawaii on a business trip. He expects to be gone about 6 weeks.

Bernard L. McNulty has been elected president of the Marblehead Lime Co., Chicago, Ill. He was formerly general manager of the Lehigh Lime Co.

W. G. Moncrieff has been elected chairman of the board of the Swan & Finch Co., New York, manufacturer of refined oils, succeeding Henry Fletcher, resigned.

Frank Nickerson, for 9 years connected with the San Francisco office of the Midvale-Cambria Steel Co., has severed his connection with that company to accept the position as southern California manager for the Bethlehem Steel Corporation. About the first of January he will open an office in the Washington Building, Third and Spring Sts., Los Angeles, Calif., for the Bethlehem Steel Corporation, covering all of southern California and Arizona.

Prof. Frederick Soddy, of Oxford, England, and Dr. F. W. Aston, research fellow of Trinity College, Cambridge, England, have each been awarded a Nobel prize, for 1921 and 1922, respectively.

The board of governors of the Synthetic Organic Chemical Manufacturers' Association of the United States has elected H. F. Wilmot technical adviser to the association in matters involving administration of customs duties under the present tariff act. Mr. Wilmot was president and a director of the Tinc Tura Laboratories, Brooklyn, N. Y., and has severed his connection with that organization in order to devote his entire time to his new duties with the association. His office will be Room 1648, Equitable Building, 120 Broadway, New York City.

Market Conditions

In Chemical, Metallurgical and Allied Industries

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities
Prevailing Prices and Market Letters From Principal Industrial Centers

In the Upward Swing of the Business Cycle

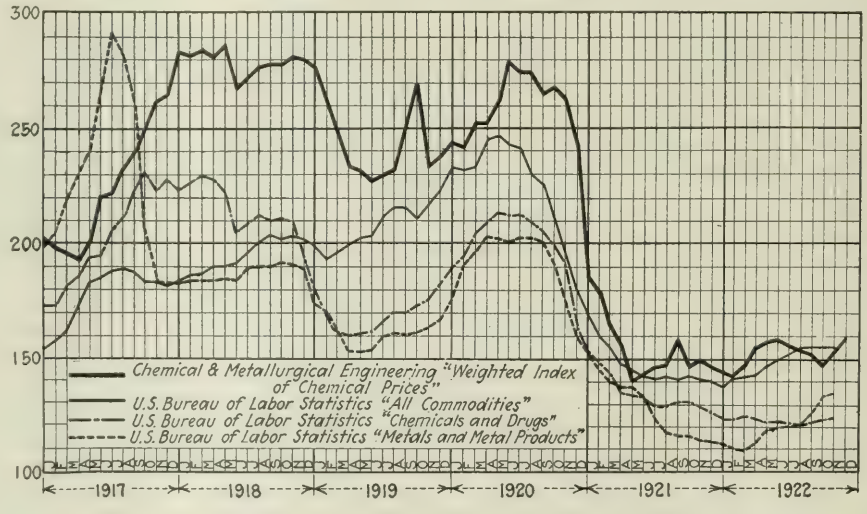
Basic Industries Continue to Gain as Commodity Prices Rise and the Volume of Manufacture Shows Substantial Increase

Forecast: *The outlook for the remainder of 1922 and the first half of 1923 is for rising wholesale prices and an expansion of business activity, with the strong probability of a continuation of the upward swing during the second half of next year. The recovery of business has been very substantial, as shown by the marked rise of the business curve of our index chart since January.*—Harvard Economic Service.

A BROAD SURVEY of present industrial conditions reveals abundant evidence that we are in the upward swing of the business cycle. Ever since the beginning of the year there has been an advancing level of prices together with a substantial increase in productive activity. Starting at first with the basic industries of iron and steel, fuel, building materials and agricultural products, this movement has broadened until at the present time practically every line of business activity has been favorably affected by it. October and November marked almost complete recovery from the labor troubles that had threatened to tie up the transportation and coal supply of the country. Production in the bituminous mines has so far exceeded current consumptive requirements that now we are practically on an even footing with 1921. Car loadings during October were at a maximum and by Nov. 1 the shortage of railroad cars was the largest on record. An expected seasonal decline in revenue freight loadings, however, during the week ended Nov. 8 reduced this shortage to 174,498 cars, a decrease of 4,000 cars. Additional relief during the week ended Nov. 15 reduced the shortage to 153,291 cars, but the transportation situation is still a serious obstacle in the path of further business expansion.

Rising Prices

Following the decline in September there has been a sharp rise in wholesale prices that has affected practically all commodities. The Bureau of Labor Statistics' general index had increased from 138 to 155 during the period January to August. In September lower prices for coal caused the index to drop to 153, but October marked a recovery to 154. Especial strength was shown in the textile, hide and leather, chemical and metal groups. From Oct. 1 to Nov. 1 Bradstreet's index rose from $12.5039 to $13.3482, a gain for the month of 6.7 per cent. This marks the highest level since December, 1920, and is the fourteenth month in the past seventeen that this index has advanced.



THE TREND OF CHEMICAL AND METAL PRICES

During the early months of 1922 the commodities on which *Chemical & Metallurgical Engineering's* weighted index of chemical prices is based showed a more striking increase than was evident for most commodities. The result was that some readjustment took place during the summer months and from its high level of June this index fell steadily during July, August and September. In October it stood at 153.10 and the effects of the tariff had just begun to be felt. During November there was substantial increase and the average for the month was 159.77, the highest point reached since early in 1921.

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	160.60
Last week	162.45
December, 1921	145
December, 1920	245
April, 1918 (high)	286
April, 1921 (low)	140

Included in this index are acetic, citric, hydrochloric, nitric, and sulphuric acids, ethyl and methyl alcohols, anhydrous ammonia, ammonium sulphate, barium chloride, bleaching powder, borax, caustic potash, caustic soda, copper sulphate, formaldehyde, glycerine, potassium carbonate, salt cake, soda ash, sulphur, benzene, aniline, and cottonseed and linseed oils.

The expanding volume of manufacture has been accompanied by increased employment in industrial establishments. Gains in the total amount of the payrolls in October as compared with September indicated larger earnings for the individual workers. The Department of Labor reports are based on 3,064 establishments in 43 different manufacturing industries employing 1,525,785 workers and paying out $47,051,229 per week in wages. Comparing the figures for October, 1922, with those for identical establishments for September, 1922, there were increases in the number of employees in 29 of the 43 industries. Glass, foundry and machine shops, textiles, iron and steel and chemicals show increases ranging from 5.9 to 4.6 per cent. Strikes in the pottery industry caused a decrease in employment in that industry of 30.9 per cent. Fertilizers, largely because of seasonal character, showed a decrease of 6.8 per cent. Thirty-four of the 43 industries reported increases in their payrolls for October as compared with September. Since the increase in payroll accounts are greater than the increase in numbers employed, it is evident that wages have been advanced or that hours of work have been extended.

The output of pig iron and steel

Trend of business conditions in the United States based on Bradstreet's price index and bank clearings outside of New York as computed by Harvard Economic Service.

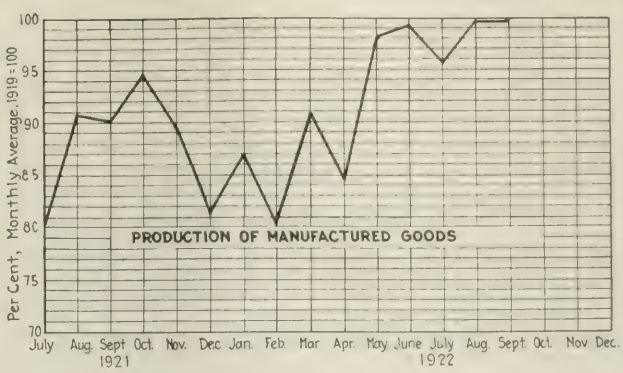
1922

Index of the volume of manufacture of steel, lumber, paper, petroleum, textiles, leather, food and tobacco compiled by Federal Reserve Board.



ingots, the consumption of cotton and silk and the output of portland cement all exceeded in October any previous month since 1920. The production of pig iron for October was the largest for any month since December, 1920, and exceeded by more than 200,000 tons the production for July, which was the record month for 1922.

The total production of newsprint in October was 130,682 net tons, as compared with 101,884 tons in October, 1921. This brings the total for 10 months of 1922 up to 1,200,301 tons, or about 188,000 tons more than for the same period of the preceding year.

Stocks of hides and skins at the end of September, the last month for which statistics are available, showed another increase and were the largest since last March. The production of sole and belting leather increased, although less upper leather was made than in August.

Cement production during October was 12,287,000 bbl., a new high record. This compares with 10,506,000 bbl. in October, 1921.

Meltings of raw sugar were somewhat less than in September (280,003 long tons, as compared with 321,909 tons), but nevertheless exceeded those for October, 1921.

The Stock Market Reaction

After security values had a phenomenal rise and the *Wall Street Journal* average for twenty industrials had reached a new high value for the year of $103.43, a sharp decline set in, affecting the common stock of a wide range of companies. Various reasons have been assigned for this reaction, but the one most generally held is that it represents the accumulation of a number of disquieting economic developments. Prominent among these is the situation in Congress and the threatening passage of class legislation such as the ship subsidy, farmers' loans, governmental financing of plans for the distribution of farm products, proposed re-enactment of the excess profits tax, reduction of freight rates and amendments to the Federal Reserve Act. Should such radical measures be enacted into law at this time it is evident that a fatal blow would be dealt to the future improvement of business.

The St. Louis Market

St. Louis, Mo., Nov. 29, 1922.

The firmness of the heavy chemical market during the past few weeks has been further exemplified by several important advances. These have tended toward inducing large buyers to anticipate their future requirements, resulting indirectly in a very active market. Stocks of most important items are very limited and on some items spot stocks are not to be located, while producers report having sold up their production for several months ahead. An easier feeling is observed for imported material, prices having fallen appreciably in some cases. Transportation facilities are somewhat better but are still below normal. It is evident that buyers should give this condition their serious consideration when placing orders.

Alkalis

Only routine business is being transacted in *caustic soda* and prices remain the same. The same may be said about *soda ash*, though more small purchases of ash are being made. Prices on ash are generally steady, though in a few instances they have been slightly shaded. *Bicarbonate of soda* has shown more life recently and prices are firmer than when we last reported. *Sal soda* has been fairly active recently and a number of good-sized less than carload lots orders have been placed. Quotations are as follows: Barrels, $1.65 per 100 lb.; kegs, $1.85; packages, $2 per case.

General and Special Chemicals

The heavy *mineral acids* have not been displaying unusual activity since our last report; however, the demand has been very good for this time of the year. No change in prices has been reported for some time, but the market is firming up quite a bit. Producers of *acetate of lime* have made a further advance in price which has also made a corresponding increase in *acetic acid* and *formaldehyde*, with quite a heavy demand for the latter, particularly in small lots. Supplies of *citric acid* are apparently adequate to meet the present demand, which is only moderate. Large quantities of imported material can be had, but domestic goods are not so free. *Oxalic acid* is reported very active, and the competition from imported goods has been keenly felt by the domestic manufacturers. *Aqua ammonia*, 26 deg., is very quiet, which is not unusual for this time of the year. *White arsenic, powdered*, is quoted at 14c. f.o.b. New York, with no spot goods available, and a further advance in price would not prove surprising. There is no relief looked for for some time, as the domestic production is very limited due to many of the American smelters having curtailed their operations. There has been very little change in the *copperas* situation, the demand still far exceeding the production. Prices have been very firm and no change is looked for in the immediate future.

Sales of moderate quantities are being made on *cream of tartar*, and while *tartaric acid* is generally active, the average sale involved is comparatively small. *Glycerine* has not changed; for some time the price has been firm at 18½c. in drums with a large volume of business being transacted. The market for *yellow prussiate of potash* is apparently devoid of any spot stocks, and for future shipment from abroad prices are being quoted at around 38@38½c. f.o.b. New York. The demand for *sodium benzoate* has kept up unusually well considering the fact that the preserving and canning season has come to a close. *Zinc sulphate* remains very strong, with an extremely large demand. Prices are reported at 3⅝c. per lb. in carlots f.o.b. St. Louis, and at 3¾@4c. per lb. in less than carload lots f.o.b. St. Louis. The *zinc dust* market is very much improved, the product being quoted at 10c. per lb. in carloads, f.o.b. New York.

Vegetable Oils and Naval Stores

Castor oil, after declining to 13½c. in drums, has steadily held its own, and a present active demand would indicate no further decline for some time. Today's quotations for *linseed oil* do not differ greatly from recent reports. Single-barrel lots are being quoted at $1 basis raw oil; 5-bbl. lots at 92c., with the usual differential of 2c. for boiled over raw. *Turpentine* is slightly weaker than previously reported, the market today being $1.52 in 5-bbl. lots; $1.58 in single barrels, a decline of 10c.

On Nov. 20 a general advance in prices on *barytes, blanc fixe* and *whiting* became effective in this market. The largest producer here quotes as follows: *Barytes*, $26@$28 per ton for water ground and water floated material. Water ground and water floated *whiting* sells for $17@$19 per ton. *Blanc fixe* is being sold at $90 per ton. A good volume of business in these items is being reported. *Zinc oxide* is very firm and an advance in price is daily expected. An active market is reported, with prices as follows: Carloads in barrels, lead free, 7¼c.; 5 per cent lead, 6¾c.; 8 to 10 per cent lead, 6¼c. Carloads in bags, ¼c. less. Less than carload lot prices, barrels, ¼c. over carload lots. These prices are ex-warehouse St. Louis.

The Iron and Steel Market

PITTSBURGH, Dec. 1, 1922.

There is no evidence of any decrease in the rate of steel production, which was, in ingots, at the rate of 40,000,000 tons a year in October and probably ran a trifle above that in November. There is an increase of fully 15 per cent over the average rate April to September inclusive, when production was less than the demands of buyers, although it is not certain that buyers would have been as anxious to obtain heavy deliveries if the coal strike had not occurred.

Shipping conditions are far from good, but they permit of shipments fully equal to current production, while only a few producers desire greater facilities for moving coal and coke than have been at their command in the past few weeks. Some consignees are affected by the many embargoes.

The finished steel market as a whole is very quiet in point of tonnage turnover, and indeed has been very quiet for more than a month. Mill operations are based very largely on old orders and interest centers mostly on the question of how long old orders will carry the mills. The Steel Corporation is booked many months ahead in most of its lines. Among the independents, there are heavy order books in tubular goods and a fairly large tonnage in wire products, with a moderate tonnage in merchant bars. In plates, shapes, tin plate and sheets there is not so much business, and in the case of some mills not enough to support the present operating rate fully through December.

STEEL PRICES

A motion is prevalent that finished steel prices are destined for declines in the not distant future. The distinction is not made as clearly as it should be between bars, shapes and plates, in normal times the market leaders, and pipe, wire, sheets and tin plate. The former group, if the market be taken as really established at 2c., are distinctly high, their low point having been 1.35c., early in March. The other products have advanced less in dollars per ton and much less in percentage. The effect of wage advances since March, counteracted in part by reductions in freight rates, represent a net increase in cost of something like $5 a net ton upon finished steel products as a whole.

As to prospective declines, while 2c. is the commonly quoted market on bars, shapes and plates, attractive orders have been going at less in recent weeks, so that a readjustment might not really mean much after all. In sheets and tin plates, the independents have not fully recovered from their disappointment that the price announcement of the Steel Corporation 8 days ago did not involve advances, so that it is no time to predict declines in those quarters. In pipe, there is still great pressure upon mills for deliveries, particularly in the smaller sizes, and the same is true to an extent of nails. Tubular goods may be considered very strong marketwise and wire products moderately strong. Markets are: Wire, 2.45c.; nails, $2.70; blue annealed sheets, 2.50c.; black sheets, 3.35c.; galvanized sheets, 4.35c.; automobile sheets, 4.70@5c.; merchant pipe, 66 per cent basing discount.

The sheet bar market is poorly defined and will not be well established until business comes to be done on a large scale for the first quarter of next year. The usual contract price for the current quarter was $38 Pittsburgh or Youngstown. For a time prompt lots brought $40 readily. Recently there have been sales at various prices, particularly sales by Cleveland producers to Cleveland consumers, at less than $38, but from such sales one cannot compute a market price at the usual basing points Pittsburgh and Youngstown from the awkward circumstance that one does not know whether adding or deducting the freight would be the proper thing. Probably some tonnage of fourth quarter business will have to be carried over on account of buyers not being able to specify in full. A fair guess seems to be that the first quarter market will not be under $33 nor over $35. Billets, which are but lightly traded in, are commonly quotable at the same price as sheet bars.

COKE AND PIG IRON

A week ago it was noted that coke was not running with coal, coke having advanced, while coal had declined. This week coal is at variance with itself. Pittsburgh steam coal is quotable at $2.75 and Connellsville steam coal, probably chiefly Sewickley vein, at $2.25@$2.50, whereas reasonably good byproduct coal is all of $3 and good grades run up to $3.50 at least, Youghiogheny gas coal is at approximately the same range. In normal times the differences between grades are relatively very slight. Connellsville furnace coke for spot or prompt shipments is $7.25@$7.50, but with $8 or more quoted for regular shipment over December, and $8 quoted for first quarter, prices which do not interest furnacemen.

Valley pig iron has continued to decline. Transactions do not run into tonnage, and there are variations between prices in actual sales, suggesting either that buyers do not cover the market ground carefully or consider other circumstances than price, such as quickness of delivery. Some carload sales of foundry iron have required instant shipment. Bessemer iron is offered at $28.50, with scarcely any takers, against $30 quoted a week ago. Basic seems to be available now at about $25.50. There was a sale early in the week at $26 and report, apparently authentic, of a sale at $27.50. Foundry iron can be picked up at $26.50, but some furnaces are getting $27.50 on single carloads, chiefly, no doubt, from consumers accustomed to a certain brand. Prices mentioned are f.o.b. valley furnaces, freight to Pittsburgh being $1.77.

The New York Market

NEW YORK, Dec. 4, 1922.

The chemical and allied markets showed only moderate activity during the past week, due probably to the intervening holiday. The outstanding interest of the week was again centered around the arsenic market and new high levels for the year were recorded. Producers of acetic acid advanced all grades, because of the recent rise in the price of acetate of lime and they report a steady demand from consumers for fair-sized packages. American refiners announced a second advance of 3c. per lb. in camphor, bringing present figures around 96c. per lb. Manufacturers of bleaching powder report a heavily sold up condition at the works and are quoting high prices for early shipments. Prussiate of soda has shown some tendency to ease and prices were somewhat lower during the late trading. Prussiate of potash, on the other hand, was scarce, with the demand very strong for the yellow and red varieties. The alkali market continued along steady lines at the same levels as previously recorded. Export demand was for moderate quantities and came chiefly from Italy and Japan. The domestic demand continued exceptionally active and contracts over 1923 were recorded among leading producers. Barium chloride, formaldehyde, permanganate of potash, bichromate of potash and soda, sodium acetate and cyanide continued along steady lines, with very little selling pressure in any direction.

GENERAL AND SPECIAL CHEMICALS

Alcohol—Leading producers report a fairly active demand from consumers and state that supplies are sold ahead for the remainder of the year. Second-hand stocks have been greatly diminished and competition was less noticeable. Producers quote denatured 188 proof No. 1 formula at 37@39c. per gal. Methanol continued at $1 per gal. in drums for the 95 per cent and $1.03 per gal. for the 97 per cent.

Arsenic—Commercial material recorded a new high record for the year when spot material sold at 15c. per lb. Domestic producers are heavily sold

ahead and importers are experiencing some difficulty in obtaining any appreciable tonnages from Japan or Germany. Shipments have sold up to 14c. per pound.

Bleaching Powder—Producers have been unable to offer any prompt shipments and prices have advanced to $2.25 per 100 lb. f.o.b. works. Consuming demand is quite satisfactory and several contracts over 1923 were reported around $1.90@$2 per 100 lb. in large drums, f.o.b. works.

Carbonate of Potash—Calcined 80-85 per cent was quoted around 6c. per lb. Shipments were held at 5½c. per lb., duty paid. Hydrated 80-85 per cent was very scarce at 8c. per pound.

Caustic Potash—Imported 88-92 per cent material was steady at $6.50 per 100 lb. on spot. Shipment prices were at the same levels as spot goods.

Caustic Soda—Export demand has not shown any noticeable change and leading sellers quoted the market around $3.50@$3.60 per 100 lb., f.a.s. N. Y. The domestic inquiry continued exceedingly strong at $3.75@$4 per 100 lb., ex-store. Contracts over 1923 were recorded at $2.50 per 100 lb., basis 60 per cent, carload lots, f.o.b. works.

Copper Sulphate—Producers reported a very good demand and stated that November, 1922, business was more than double that of November, 1921. The insecticide and agricultural industries are showing inclinations for future requirements. Standard 99 per cent large crystals were quoted at $5.75 per 100 lb., in carload quantities.

Prussiate of Potash—Yellow material was very strong during the early part of the week, but later reacted somewhat. Prices opened around 40c. per lb. and declined to 39½c. Red material was scarce at 95c. per pound.

Prussiate of Soda—The general tone of the market was barely steady and prices recorded a fractional decline. Consumers showed very little desire to purchase any round quantities and resale merchants quoted down to 21c. per lb. for spot goods.

Coal-Tar Products

Dealers in crudes and intermediates reported a steady tone to the market, with supplies in several items heavily sold ahead for the remainder of the year and well into 1923. Among the most important were benzol, cresylic acid, solvent naphtha, salicylic acid and phenol. Producers of salicylic acid announced another increase of 5c. per lb. on the U.S.P. and technical grade.

Benzol—There has been no material relief in this market, even though producers announced increased production. Spot goods remain in very limited supply at 38@40c. per gal. for 90 per cent.

Cresylic Acid—Spot goods are in limited supply and prices are quite firm. Sales of 97-99 per cent material were recorded around 85c. per gal., with 95 per cent goods at 80c. Producers quote unchanged prices for contracts, but report a heavily sold up condition.

Phenol—The market exhibited signs of weakness, due to the sudden advance in quotations. Consumers showed little inclination to purchase at the present high levels and second-hand dealers were eager to book business as low as 32c. per pound.

Aniline Oil—The demand continued along steady lines and sellers' quotations were firm around 16@17c. per lb. Aniline salts also showed a tendency to maintain current figures and were held at 24@26c. per pound.

Beta Naphthol—The technical material is held firm among leading factors at 25@26c. per lb. Consumers have shown greater interest and purchases were for larger packages. The general range is around 24@26c. per pound.

Salicylic Acid—Producers announced an advance of 5c. per lb., bringing present levels for U.S.P. to 40c. per lb. Demand is fairly active and producers report a satisfactory volume of business at the works. Higher costs of raw material were responsible for the late advances.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

California

OAKLAND—The Rhodes-Jamieson Co. has commenced the operation of a new plant on the Oakland estuary, near High St., for the manufacture of composition tile products. It is proposed to develop an output of about 10,000 tiles per day. The company has a 5-acre tract to provide for future expansion.

SAN FRANCISCO—The San Francisco Sulphur Co., 624 California St., has filed plans and will commence the immediate erection of its proposed 1-story sulphur-refinery, 137x138 ft., on West Grant Ave., to cost about $35,000. The equipment installation will be arranged at an early date.

FRESNO—The Zellerbach Paper Co., Kern and H Sts., has awarded a contract to Minard & Casteel, 319 Abbey St., for extensions and improvements at its local works to cost about $12,000.

Connecticut

WATERBURY—The Gulf Refining Co., 364 Railroad Hill, will construct a new storage and distributing plant on South 5th St., with oil tanks, etc., to cost approximately $25,000.

Delaware

WILMINGTON—J. C. Rhoades & Sons, 11th St. and the Baltimore & Ohio R.R., manufacturers of leather products, are taking bids for the erection of a 1-story addition.

Florida

TAMPA—The Sulphur Springs Chemical Co. has preliminary plans in progress for the construction of a new plant in the Sulphur Springs section. James Langdon is president.

TAMPA — The Imperial Oil Co., 6006 Branch Ave., recently formed with a capital of $100,000, has plans under way for the construction of a new storage and distributing plant on local site, comprising a number of buildings, tanks, etc. A. M. Allen is general manager.

Iowa

WEST DAVENPORT—The Marquette Cement Mfg. Co., 140 South Dearborn St., Chicago, Ill., is taking bids for the erection of a new building at its local mill to cost about $100,000.

Louisiana

MONROE—The Keystone Carbon Co. has plans in progress for the erection of a new 2-unit carbon black plant on local site. The equipment installation will be arranged at an early date.

ELIZABETH—The Calcasieu Sulphur Co., recently organized under Delaware laws with a capital of $2,000,000, has plans in progress for the erection of a new local mill for the manufacture of kraft and other papers from pine and forest waste. A byproduct plant will be established for the production of turpentine, pine oil, rosin, etc. The initial unit will cost in excess of $150,000. J. F. Carter is general superintendent.

NEW ORLEANS — The Louisiana Celotex Co., manufacturer of fiber board products from sugar cane waste, has plans under way for the erection of two new plant units, to double the capacity of the present mill. The work is estimated to cost about $1,000,000, including machinery. E. G. Dahlberg is president.

Maine

SABATTUS—The Pine Tree State Rubber Heel Co., recently organized with a capital of $200,000, has acquired a local brick mill, and will commence the immediate installation of machinery for a new plant. The initial equipment will provide for a working force of about 40 persons, and this will be increased at an early date to about 150 operatives. Frank W. Hodges and Theodore D. Cowen, both of Malden, Mass., formerly connected with the Converse Rubber Co., of this place, are president and treasurer of the new organization, respectively.

BATH—The Texas Co., 17 Battery Place, New York, N. Y., manufacturer of petroleum products, is reported to have acquired the local shipyard of the Emergency Fleet Corp., and will use the property for a new oil storage and distributing plant.

Maryland

BALTIMORE—The Crown Oil & Wax Co., Pratt and 8th Sts., has plans in preparation for the construction of two new 1-story additions to cost about $13,000. Work will be commenced at an early date. The structures will replace the portion of the plant recently damaged by fire.

BALTIMORE—The Air Reduction Co., 342 Madison Ave., manufacturer of industrial oxygen, acetylene, etc., has plans in progress for the erection of a new plant on East Fayette St., near 11th St.

BALTIMORE—The Colonial Concrete Products Co. has awarded a contract to the John Waters Building Co., 28 East Centre St., for the construction of a 2-story plant addition, 15x100 ft. Theodore W. Pietsch, American Bldg., is architect.

BALTIMORE — The Baltimore Brick Co., Maryland Trust Bldg., will construct five additional kilns at its plants, three to be located at Highland Ave. and Monument St., and two at Loney's Lane and Monument St., estimated to cost about $15,000.

Massachusetts

WATERTOWN — The Hood Rubber Co., Nichols Ave., manufacturer of automobile tires and other rubber products, will soon commence the erection of a 4-story plant addition, to be known as Factory No. 53, estimated to cost approximately $60,000. F. C. Hood is general manager.

NORTH BROOKFIELD—The Asbestos Textile Co. will commence the immediate construction of a new addition, 30x50 ft. J. J. Lang is superintendent.

ACTON — Fire, caused by an explosion, Nov. 18, destroyed two of the mills at the local plant of the American Powder Co. An official estimate of loss has not been announced.

ANDOVER—The Tyer Rubber Co., recently reorganized, is planning for enlargements in its local plant for the production of additional lines of rubber goods, continuing in the manufacture of automobile tires, druggists' goods, etc. Stock has been issued for $530,000. Myron H. Clark is president, and Walter E. Piper, treasurer.

Michigan

MUSKEGON—The Central Paper Co. has commenced excavations for a new mill addition to cost about $200,000, including equipment.

Minnesota

DULUTH—The Universal Portland Cement Co., 210 South La Salle St., Chicago, Ill., is planning for the construction of a new 1- and 2-story mill at its plant in the Morgan Park section, estimated to cost about $235,000, including equipment. R. S. Huey is local superintendent.

Missouri

KANSAS CITY—The Kansas City Oxygen Gas Co., 1805 Grand Ave., is taking bids for the erection of a new 2-story ammonia and nitrate plant, 20x48 ft., at Centropolis Station.

ST. LOUIS—The Brauer Mfg. Co., manufacturer of leather products, has acquired a building at 817-19 North 17th St., for a new local plant. The structure will be remodeled and improved, and equipment installed at an early date.

Nevada

FALLON—The Board of Education will install a chemical laboratory in the new Churchill County High School, for which plans have been completed. Erection will be commenced at an early date.

BELLEHELEN — The Bellehelen Merger Mines Co., operating on a tract of about 75 acres, is perfecting plans for the construction of a new mill, with capacity of 50 tons per day, estimated to cost approximately $125,000. A. E. Strong, Denver, Colo., is consulting engineer.

New Jersey

TRENTON—The Maddock Pottery Co., 3rd St., manufacturer of chinaware, will make extensions and improvements in its local plant. The contract has been awarded to the Karno-Smith Co., Broad St. Bank Bldg.

TRENTON—The Semple Mfg. Co., recently organized to take over the assets of the Semple Rubber Co., defunct, will operate at the former mill of the Sanhican Rubber Co., in the Brookville section. Equipment from the former Semple works will be installed, and production concentrated on rubber tubes and tubing. C. H. Semple is president, and W. B. John, treasurer.

TRENTON—The Empire Tire & Rubber Co., Clinton Ave., will build a 1-story addition 50x90 ft.

BOUND BROOK — The Fischer-Sweeny Bronze Co., 312 Adams St., Hoboken, N. J., manufacturer of bronze, aluminum and other metal castings, has acquired a 1-story building at Bound Brook, totaling about 16,000 sq.ft. of floor space, and will use for a new foundry. It is purposed to concentrate operations at this location, and the present plants at Hoboken and Newark will be removed here.

New York

DUNKIRK—The Atlas Steel Corp. is perfecting plans for extensions and improvements at its local plant, and at its branch works at Charleroi, Pa., to cost in excess of $250,000, including equipment. L. J. Campbell is chairman of the board.

Ohio

SANDUSKY—The Diamond Fertilizer Co., Market St., is planning for the erection of a new 1-story addition to its plant, 100x140 ft.

CLEVELAND — The Cleveland Waterproof Paper Co., 2033 West 106th St., has acquired property on the Berea Road, N.W., near the line of the New York Central R.R., as a site for a new plant for the manufacture of waterproof and mothproof papers. Plans have been prepared and work will proceed at once.

CINCINNATI—The Cincinnati Galvanizing Co., McMicken St., has authorized plans for the erection of a new 2-story plant at Chickering and Spring Grove Aves., estimated to cost about $150,000, including equipment. C. J. Hiefer, 810 Fourth National Bank Bldg., is engineer.

WARREN—The Alloy Electric Steel Casting Co. has work nearing completion on a new foundry for the production of alloy steel castings, and plans to have the structure ready for operation early in the coming year. The equipment installation will include a 15-ton furnace.

SPRINGFIELD—The Fairbanks Co., manufacturer of piano plates and other castings, plans for the rebuilding of the portion of its plant destroyed by fire, Nov. 13, including pattern shop, with loss approximating $50,000, with equipment.

RITTMAN—The Ohio Match Co., Wadsworth, O., has authorized the preparation of plans for the construction of a new plant on local site. Details and estimates of cost will be made at once. Christian, Schwartzenburg & Gaede, 1900 Euclid Ave., Cleveland, are engineers.

Oklahoma

OKLAHOMA CITY—The Kenyon Brick & Tile Co., 2700 West 10th St., has plans in progress for the erection of additional units at its plant to increase the output to about 40,000 bricks per day. At a later date, further extensions will be made to advance the capacity to close to 100,000 bricks daily, with departments for the manufacture of face brick and ceramic tile. Considerable new equipment will be installed. A. W. Kenyon is president.

PERRY—G. T. Braden, Tulsa, Okla., has acquired a local site for the construction of oil refinery, with department for gas production from residual oils. Plans will be prepared at an early date.

PICHER—The Buffalo Mining Co. has tentative plans under consideration for the rebuilding of its milling plant, recently destroyed by fire with loss of about $100,000, including equipment.

Oregon

SALEM—The Oregon Pulp & Paper Co. has awarded a contract to Van Patten & Son, Salem, for the erection of a 4-story,

reinforced-concrete plant addition, to cost about $50,000.

OREGON CITY—The Hawley Pulp & Paper Co. is completing plans for the erection of a complete new plant unit to practically double the capacity of the present mill. It is estimated to cost close to $1,500,000, including machinery. W. F. Hawley, Sr., is president.

GRESHAM — The Columbia Brick Works have plans nearing completion for the construction of a new addition, consisting of a number of buildings, designed to double the present plant capacity. New kilns will be built and new machinery installed.

Pennsylvania

YORK—The Gilbert Wall Paper Co., 728 Linden Ave., Paul C. Gilbert, president, has rejected bids recently received for its proposed new plant, and will have revised plans prepared at an early date. The plant will be 2-story and basement, 85x325 ft., located at State St. and the Pennsylvania Railroad. A power house will also be built. New bids will be called late in January. J. A. Dempwolf, Casset Bldg., is architect.

PHILADELPHIA—The Department of Water, City Hall, is arranging an appropriation of $90,000 for the purchase of chemicals for the waterworks during the coming year.

MARS—The Velte Foundry & Machine Co. has tentative plans under consideration for the rebuilding of the portion of its foundry and pattern shop, destroyed by fire, Nov. 23, with loss estimated at about $40,000, including equipment.

LEWISTOWN—The American Refractories Co., Union Arcade, Pittsburgh, has acquired a large tract of property near Lewistown Junction, and plans for the development of the site for refractory production at an early date.

PHILADELPHIA — The Keystone Chemical Co. has leased property at 24th South Front St. for a local works.

South Carolina

EASLEY—The Easley Oil Mill Co. is said to be planning for the rebuilding of the portion of its local plant, destroyed by fire, Nov. 16, with loss estimated at $30,000, including equipment.

Tennessee

CHATTANOOGA—The Odorless Refrigerator Co., West 1st St., near Pine St., has construction in progress on a 2-story and basement addition, 80x125 ft., to be equipped as an enameling plant. W. H. Sears, 905 James Bldg., is architect. Gaston G. Rauol is president.

Texas

PIONEER—The American Oil Co., Tulsa, Okla., has completed plans for the construction of a new local oil refinery. The first unit will have a capacity of about 2,500 bbl. per day, and will be supplemented with a second unit of like size at an early date. T. J. Ryan is president.

STAMFORD—The Rule-Jayton Cotton Oil Mill Co. has completed plans and will break ground at an early date for its proposed new oil mill, estimated to cost in excess of $80,000.

Virginia

CLIFTON FORGE—Eugene Mathews & Co. are planning to purchase machinery for local clay mining operations, including grinding equipment, driers, etc., for preparing the material for market. Inquiries are being made.

West Virginia

CHARLESTON—The St. Albans Glass Mfg. Co., Massillon, O., has acquired a local plant for a new works. Extensions and improvements will be made to cost close to $30,000. Operations will be inaugurated at an early date. Louis P. Mauger is president.

CHARLESTON—The Owen Bottle Co., 1401 Nicholas Bldg., Toledo, O., is completing plans for its proposed new 1-story plant on local site, 120x200 ft., estimated to cost about $150,000, and will commence work at an early date. It will be an addition to the present plant now operated in this section. The Devore Co., Nicholas Bldg., Toledo, is engineer. E. D. Libbey is president.

PARKERSBURG — The Blackwood Electric Steel Co., recently organized with a capital of $150,000, has plans practically completed for a new local foundry for the manufacture of alloy steel castings, and will break ground at an early date. The installation will include an electric melting furnace. F. S. Blackwood, head of the Farrell-Cheek Foundry Co., Sandusky, O., is president and general manager of the new company.

Industrial Developments

RUBBER—The Goodyear Tire & Rubber Co., Akron, O., has increased production from 20,600 to 21,000 automobile tires per day, and plans to advance this to 26,000 casings daily at an early date.

Stockholders of the Smith Tire & Rubber Co., Passaic, N. J., are perfecting plans to take over the plant from the receiver, William L. Brunyate, at an early date, and will place the works in immediate operation.

The B. F. Goodrich Co., Akron, O., has increased production 2,000 tires a day since the early part of November.

The Boston Woven Hose & Rubber Co., Boston, Mass., is maintaining active production at its plant, with regular working force.

The Carlisle Tire Corp., Stamford, Conn., has closed its local plant, throwing about 135 men out of employment. Lack of orders, owing to the winter season, is said to be the cause

The Firestone Tire & Rubber Co., Akron, O., is arranging for increased production at its local mill. The Miller Rubber Co. and the General Tire & Rubber Co., in this same district, are also advancing their outputs and adding to the working forces.

The Lee Tire & Rubber Co., Conshohocken, Pa., is maintaining full production at its local mill, with regular working quota.

METALS—The United States Smelting, Refining & Mining Co., Salt Lake City, Utah, is increasing operations at its local properties and adding to the working force.

The Keystone Foundry Co., Lebanon, Pa., is placing a new plant addition in service, recently completed, and will develop maximum output in the line of machine molded soft gray iron castings.

The Miami Copper Co., Miami, Ariz., is operating five sections of its concentrating plant, only one section being idle. The plant is now running on about 5,000 tons of ore per day, the production of the local mines.

The American Smelting & Refining Co. has placed its four copper furnaces at Matehaula, San Luis Potosi, Mexico, in full operation, with a total daily capacity of 950 tons of ore.

The Success Mining Co., Wallace, Idaho, is operating with two shifts at its mill, and plans to advance to a full three-shift basis in the near future. Production at the mines is being increased.

The Anaconda Copper Mining Co., Great Falls, Mont., is operating its local electrolytic plant at maximum capacity. It is reported that extensions will be made in the plant for greater output.

The Callahan Zinc-Lead Co., Cœur d'Alene, Idaho, has placed its local mill on a full time, capacity basis.

The Calumet & Hecla Mining Co., Calumet, Mich., is increasing the working forces at its mines and mill. Increased capacity is being developed at the smelter. More than 3,600 men are now employed.

IRON AND STEEL—The Falcon Steel Co., Niles, O., has resumed production on a full time basis at its local bank of 8 mills.

The Replogle Steel Co. has placed the second furnace in blast at its Wharton, N. J., plant, and is operating at the mill at its Scrub Oak mines. Mining operations at the latter point will be commenced at an early date.

The Reading Iron Co., Reading, Pa., is arranging to resume operations at its puddle mill at Birdsboro, Pa., early in December. The plant has been idle for about 24 months past. It is also expected to resume at the Birdsboro sheet mill at an early date.

The A. M. Byers Co., Pittsburgh, Pa., is operating its blast furnace in the Youngstown, O., district, with 70 puddle furnaces, two turns at the bar mill, and one turn at the plate mill.

The Thomas Iron Co., Dover, N. J., has recently completed a new concentrating mill at its Richards Mine, electrically operated, and will have the unit in full service in the near future.

The Inland Steel Co., Chicago, Ill., is advancing production to better than 75 per cent of normal at its local mills, the highest since the coal and railroad strikes.

The United States Steel Corp. is holding at 100 per cent capacity production at its Youngstown, O., plants.

The Weirton Steel Co. has placed its Clarksburg, W. Va., plant on a full capacity basis, with full working force, following a two-thirds output schedule, as operative for some time past.

The National Tube Co., Pittsburgh, Pa., has resumed operations at its local Riverside plant on a full capacity basis, giving employment to approximately 3,000 men.

The Republic Iron & Steel Co., Youngstown, O., has increased operations at its mills to approximately 80 per cent of normal.

MISCELLANEOUS — The General Chemical Co. is operating at its sulphuric acid plant at Pulaski, Va., and plans for the establishment of a new plant unit at an early date.

The Snyder Brick Co., Ottawa, O., is arranging to continue operations throughout the entire winter, for the first time in the history of the plant. An order has been taken for 1,000,000 hollow tile blocks.

Practically every paper mill in the New England district is running on a full-time basis, with full working forces. Newsprint plants are particularly busy, and have adopted an overtime schedule.

The Pittsburgh Plate Glass Co., Pittsburgh, Pa., is operating its plants at maximum capacity with full working forces.

The Forest Paper Co., Yarmouth, Me., has reopened its soda fiber mill, following a resumption in other departments. The wages of employees have been advanced. It is expected to develop full capacity at an early date.

All cement mills in the Lehigh Valley section of Pennsylvania are continuing operations at maximum capacity. A number of plants are arranging to maintain this schedule throughout the winter.

The National Carbon Co. has resumed production at its Clarksburg, W. Va., plant, after a shut-down of more than 24 months. Employment will be given to about 100 men, and this force will be advanced to the maximum of 250 men in the near future.

England, Walton & Co., Philadelphia, Pa., operating leather tanneries, is maintaining full production at its Chilhowee extract plant at Newport, Tenn., under 24-hour service. The output is devoted to tanning extracts.

Three out of four oil refineries at Brownwood, Tex., are now in operation, these being the plants of the Blue Ribbon Refining Co., 2,000 bbl. capacity; and Brownwood Producing & Refining Co., 400 bbl. daily capacity. The refinery of the Baney Refining Co., now idle, has a rated production of 400 bbl. per day.

The Corn Products Refining Co., New York, N. Y., has adopted a production schedule of 85 per cent of maximum at its Argo, Ill., plant, on a six-day week basis.

The Texas Farm Bureau Ribbon Cane Growers' Association, Lufkin, Tex., has commenced operations at a new local sirup mill, to be run on a co-operative basis. Following the installation of additional copper coils and other equipment, the output will be advanced.

Capital Increases, etc.

THE GENERAL PAPER CO., 411 5th Ave., New York, N. Y., has filed notice of increase in capital from $100,000 to $500,000 for expansion.

LEAS & MCVITTY, INC., 303 Vine St., Philadelphia, Pa., manufacturer of leather, has filed notice of increase in capital from $3,400,000 to $5,400,000 for proposed expansion.

THE DYE PRODUCTS & CHEMICAL CO., 200 5th Ave., New York, N. Y., has filed notice of increase in capital from $75,000 to $200,000 for general expansion.

THE NATIONAL TILE CO., Anderson, Ind., has filed notice of increase in capital from $545,000 to $872,000 for expansion.

ENGLAND, WALTON & CO., INC., Third and Vine Sts., Philadelphia, Pa., manufacturer of leather, is disposing of a bond issue of $1,500,000, a portion of the proceeds to be used for financing, expansion, etc. Spencer K. Mulford is president.

THE JOVA BRICK WORKS, INC., Roseton, N. Y., has filed notice of increase in capital from $56,000 to $500,000 for proposed expansion.

Property of the THURLOW STEEL WORKS, INC., Chester, Pa., including machinery and equipment, will be sold by E. Wallace Chadwich and Howard M. Lutz, receivers.

THE WHITAKER PAPER CO., Cincinnati, O., has disposed of a bond issue of $1,500,000, a portion of the proceeds to be used for general operations and expansion.

Property of the NIANTIC & MENHADEN OIL & GUANO CO., East Lyme, Conn., manufacturer of fertilizer products, including real estate, plant and equipment, will be offered at a public sale by a stockholders' committee, headed by Frederick P. Latimer, on Dec. 12.

New Companies

THE MERCURY TANNING CO., Newark, N. J., has been incorporated with a capital of $125,000, to manufacture leather. The incorporators are E. Roth Fast, Jacob and Louis Schrenzel. Newark. The last noted represents the company.

THE L. B. ABEL CO., INC., Waterbury, Conn., has been incorporated with a capital of $50,000, to manufacture rubber products, leather specialties, etc. The incorporators are Frank E. and Louis B. Abel, 118 North Main St., Waterbury.

THE TAYLOR PRODUCTS CO., New York, N. Y., care of M. H. Briggs, 342 Madison Ave., New York, representative, has been incorporated with a capital of $25,000, to manufacture chemicals and chemical by-products. The incorporators are J. E. Taylor and J. D. Peckner.

THE EMPIRE FLUORSPAR CO., Golconda, Ill., has been incorporated with a capital of $100,000, to operate fluorspar properties, refine lead, zinc, etc. The incorporators are Frank H. Stanbitz, Walter R. Pierce and Henry B. Pierce, all of Golconda. The last noted represents the company.

THE PACIFIC STRAW & PAPER BOARD CO., Vancouver, Wash., has been incorporated with a capital of $500,000, to manufacture strawboard, paper board and other composition products. Charles F. Schaub, care of the Chamber of Commerce, Vancouver, is the principal incorporator and represents the company.

THE CLEO MFG. CO., New York, N. Y., care of Rosett & Deutsch, 198 Broadway, New York, representatives, has been incorporated with a capital of $100,000, to manufacture chemicals and affiliated products. The incorporators are C. C. Bleakley, F. Brek and R. Eskin.

THE CELLULOSE CO., Newark Ave., Bloomfield, N. J., has filed notice of organization to manufacture celluloid products. The company is headed by P. Edward Koester, 58 Prospect St., Bloomfield.

THE MICA CERAMICS CORP., Philadelphia, Pa., care of the Capital Trust Co. of Delaware, Dover, Del., representative, has been incorporated under Delaware laws, with a capital of $3,000,000, to manufacture mica products and affiliated specialties.

THE DEARBORN GLASS CO., 1426 West Harrison St., Chicago, Ill., has been incorporated with a nominal capital of $5,000, to manufacture window glass and other sheet glass products. The incorporators are Arthur R. Levisohn and Herman R. Paulick.

THE ALLDAY OIL CORP., Eldorado, Ark., has been incorporated with a capital of $250,000, to manufacture petroleum products. The incorporators are M. L., D. H. and R. E. Allday, all of Eldorado.

THE TUNGSTEN PRODUCTS CO., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated with a capital of $525,000, under state laws, to manufacture tungsten products and conduct metallurgical operations.

THE CONSUMERS BRICK CO., 607 West 66th St., Chicago, Ill., has been incorporated with a capital of $350,000, to manufacture brick, tile, sewer pipe and kindred burned clay products. The incorporators are Thomas Bisch, Fred C. Rathje and W. L. Woods.

THE HAR-LO PRODUCTS CO., INC., Bridgeport, Conn., has been incorporated with a capital of $50,000, to manufacture varnishes, paints, etc. The incorporators are Harry T., Charles and James E. Logan, and Frederick W. Wren, all of Bridgeport.

THE PREMIER PAPER CO., New York, N. Y., care of S. S. Kogan, 299 Broadway, New York, representative, has been incorporated with a capital of $50,000, to manufacture paper products. The incorporators are S. Greenberg, J. and J. G. Gold.

THE REFUGIO GLASS WORKS, INC., Refugio, Tex., has been incorporated with a capital of $75,000, to manufacture glass products. The incorporators are W. M. Stephenson, W. L. Napier and J. K. Naylor, all of Refugio.

THE EASTERN STEEL CASTINGS, INC., Newark, N. J., has been incorporated with a capital of 10,000 shares of stock, no par value, to manufacture steel and semi-steel castings. The incorporators are John B. Brown, Robert D. Reynolds and William D. Sergent, Ave. L and Edward St., Newark. The last noted represents the company.

THE CHEMICAL ELECTRO PROCESS CORP., Seattle, Wash., has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. H. D. Horton, 6022 12th Ave., South, Seattle, is the principal incorporator and represents the company.

THE BON-LAC CORP., 1602 Continental Bldg., Baltimore, Md., has been incorporated with a capital of $25,000, to manufacture shellac, varnishes, etc. The incorporators are James S. Bond, Oliver R. Loomis and W. Fairfield Peterson.

THE BEEBE-TUNNELL CORP., New York, N. Y., care of Newman & Joseph, 291 Broadway, New York, representatives, has been incorporated with a capital of $150,000, to manufacture silicon, aluminum and kindred products. The incorporators are H. Beebe, H. E. Tunnell and B. Simon.

THE ROYAL REFINING CO., care of the Corporation Trust Co. of America, duPont Bldg., Wilmington, Del., has been incorporated under Delaware laws, with a capital of $750,000, to manufacture refined petroleum products.

THE MICHAEL MARX GLASS CO., New York, N. Y., care of Potter & Potter, 305 Broadway, New York, representatives, has been incorporated with a capital of $25,000, to manufacture glass products. The incorporators are I. Sherman, M. Wolfson and N. J. Schumer.

THE STANDARD PAPER CO., San Francisco, Calif., has been incorporated with a capital of $20,000, to manufacture paper products. The incorporators are Charles Gross, David Morris and George R. Perkins, Chronicle Bldg., San Francisco. The last noted represents the company.

Industrial Notes

THE CHEMICAL EQUIPMENT CO., Chicago, Ill., has opened a new office in New York at 109 Broad St., which will be under the supervision of G. M. Hickley, formerly of the Celite Products Co.

THE AMERICAN ANILINE PRODUCTS, INC., has acquired control of the American Vat Color Co. of Chicago and has reorganized it under the name of the American Vat Color Manufacturing Co., with main offices at 80 Fifth Ave., New York City. Ample working capital has been provided. Algol and indanthrene colors are being manufactured.

THE LINK-BELT CO., Chicago, Ill., which for many years has been issuing a large calendar, has just advised that the 1923 Link-Belt calendar will be ready for distribution early in December and that a number of extra copies are available. They can be obtained by addressing the Link-Belt Co., 910 South Michigan Ave., Chicago, on the letterhead of your firm. The calendar measures 15½x24 in., and contains twelve separate full sheets. Each has an illustration of Link-Belt machinery and equipment. Underneath each month's large calendar are shown the previous month and the succeeding month. The company also announces the promotion of W. W. Sayers to the position of chief engineer of the company's Philadelphia works and Eastern operations. Mr. Sayers was for many years a representative of the company in its Chicago territory, in the lines related to power house machinery, coal storage, Peck carriers, crushers, etc., and later in charge of the locomotive crane department. His headquarters will be at the Philadelphia office.

THE STANDARD TURBINE CORP., of Wellsville, N. Y., announces the appointment of E. E. Maher as district sales manager in Chicago, with offices at 2237 Insurance Exchange Bldg. The Chicago office will handle business for the greater part of Indiana, Illinois and Iowa. The Standard Turbine Corp. is incorporated under the laws of New York and manufactures steam turbines exclusively. J. Y. Dahlstrand, formerly associated in engineering capacities with the Allis-Chalmers Mfg. Co., the Westinghouse Electric & Mfg. Co. and the Kerr Turbine Co., is chief engineer and manager of the corporation.

THE FLORANDIN EQUIPMENT CO., 110 West 40th St., New York City, who is New York representative of the Conveyors Corp. of America, Chicago, is also representing the Perfection Grate & Supply Co., Springfield, Mass., manufacturer of hand stokers and soot cleaners.

JENKINS BROS., New York, announce the appointment of William G. LeCompte as sales manager in charge of their New York territory. Mr. LeCompte has been a member of the sales organization of this company for a quarter of a century.

THE NATIONAL FOREIGN TRADE COUNCIL, of India House, Hanover Sq., New York, announces the completion of a Selected Bibliography of Foreign Trade, 1922, in which are listed the leading authorities on various aspects of International Commerce. This 5-ft. bookshelf of foreign trade contains fifty titles dealing with training for foreign trade, the history and geography of foreign trade, the practical administration of an export business, and with all phases of ocean transportation. "We receive many requests for the titles of books on foreign trade which may be termed the leading authorities," says O. K. Davis, secretary of the National Foreign Trade Council. "To meet this demand, we have consulted a large number of representative economists, editors, educators and practical export executives in order to obtain a consensus of opinion as to which are the best books in the English language on foreign trade. The American literature of foreign trade, which was little better than nothing 10 years ago, has now grown to such proportions that a full list of titles would include several hundred books. It is obviously impossible for business men or those other than academic students of the subject to make practical use of such a list, but there is a desire and a need among those actively engaged in one or another of the different branches of overseas commerce for a brief list of authoritative references. It is primarily to meet that need that this list has been prepared. It has been impossible to include many books of recognized value; but failure to include them indicates only that other works were preferred by those consulted. Should this Selected Bibliography prove of value, the National Foreign Trade Council plans to republish it annually with such changes and additions as further investigation and the publication of new books may necessitate."

THOMAS J. KEENAN, secretary-treasurer of the Technical Photographic and Microscopical Society, has moved from 251 West 19th St., to a more central and convenient location in Room 710, Bar Bldg., 36 West 44th St., New York City.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its annual meeting in Pittsburgh, Pa., Feb. 12 to 17, 1923.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting April 3 to 7, 1923, at New Haven, Conn.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting May 3, 4 and 5, 1923, at the Commodore Hotel, New York City.

AMERICAN ENGINEERING COUNCIL, executive organ of the Federated American Engineering Societies, will meet in Washington, D. C., Jan. 11 and 12, 1913.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its winter meeting at Richmond, Va., Dec. 7 to 9. Headquarters will be at the Hotel Jefferson.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its annual meeting in New York City during the week of Feb. 19, 1923.

INTERNATIONAL CHAMBER OF COMMERCE will hold its second general meeting in Rome, Italy, March 19-26, 1923.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

NEW JERSEY CLAY WORKERS' ASSOCIATION will hold its annual meeting at the Ceramics Building, Rutgers College, New Brunswick, Dec. 12.

SOCIETY OF CHEMICAL INDUSTRY, American Section, will meet in Rumford Hall, 52 East 41st St., New York City, on Dec. 15.

SOCIETY OF INDUSTRIAL ENGINEERS, with headquarters in Chicago, will hold its spring convention in Cincinnati, April 18, 19 and 20, 1923. The major subject will be "Management Problems of the Smaller Plants."

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, East 41st St., New York City: Dec. 8—American Chemical Society, regular meeting. Jan. 5—American Chemical Society, regular meeting. Jan. 12—Society of Chemical Industry, Perkin Medal. Feb. 9—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting. March 9—American Chemical Society, Nichols Medal. March 23—Society of Chemical Industry, regular meeting. April 20—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting. May 4—American Chemical Society, regular meeting. May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting. May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.

On the Merit of Being In Business for One's Health

"WE ARE NOT in business for our health," said a man of affairs, as he turned a mean trick and offended against his obligations.

Now this notion was his misfortune. The poor devil thought he was in business only for profit; he did not know that if a business establishment is operated solely for the profit of its owners, it cannot endure. It has a liability that does not show on the balance sheet. It may seem but a phantom, but it will soon take on shape and substance. A business concern is patronized in the measure that it satisfies the needs or wants of other persons than its owners. Its very life is in its fulfillment of its obligations to its customers, to the trade. The human demands upon a business organization are as great and insistent as those upon a household. The point is obvious, but many stockholders miss it.

If we succeed and are surrounded by men of good will toward us, we are doing more for our health than we can get out of all the watering places and health resorts in the country. It is fighting and quarreling, and worrying over the fear that we may lose out, that is the killing pace.

Imagine two men engaged in producing and distributing merchandise. One has the interests of the users of his products constantly in mind. He prosecutes research for their benefit—and they buy more. He has no desire for every last penny. He wants purchasers to do well with what he sells them and is pleased when they are beholden to him for their success. If there is a squeeze in the market, he is as easy as he can be with his old customers. Then, when a slump comes along, many of them will stand by him. He has chosen his walk of life not only for his financial welfare but also for his health. He wants to live an agreeable life. Having established good will, his worry is decreased to a minimum, and this preserves his health. It is a pleasure to work for such a man.

The other has an eye only for what he can see in his balance sheet. His philosophy of trade is that if he can beat his competitors in prices the trade will belong to him. His advantage he believes to consist in cutting down production costs by the elimination of such overhead charges as research and service, and the reduction of salaries and wages. He thinks his customers are as mean as he is, that they too are not in business for their health, and that they are out for every last cent.

The last cent is the most expensive of all earnings. He who would gain it destroys his personnel, because his competent men will leave him as soon as they can. The lame ducks will stay on. He destroys his best means of reducing costs, which follows in the wake of a contented and loyal staff, anxious to improve methods. And the worry that comes from being without friends is likely to undermine his health.

The elder ROTHSCHILD once said that he accounted for his fortune by his willingness to buy at prices above the bottom and to sell at those below the top. Some hopeful rothschildettes of today have not mastered this principle.

Research Is the Plow of Industry

> Behold the days come, saith the Lord, that the plowman shall overtake the reaper, and the treader of grapes him that soweth seed; and the mountains shall drop sweet wine and all the hills shall melt.—*Amos*, ix., 13.

THAT is our text. Now follows the sermon. Observe, please, the diligence of the plowman and the wealth and prosperity which accompany it.

Research in Germany under present conditions costs about one-tenth of that for the same work in America. It is again being prosecuted with vigor by leading chemical companies. There is also such stress of need there as to make Necessity conceive many inventions. These are being brought to fruition in the various German industrial research laboratories. They provide materials and goods that are needed, short-cuts in manufacture, improvements in yields and in qualities. The American people will want them. A tariff wall will not keep them out after it becomes known that such novelties and improvements are available. The rights to produce may or may not be purchased, according to the attitude of the inventors or owners. If they are purchased, only one manufacturer will profit by them. And in patent cases the United States courts are increasing their frown at those who evade protected rights by trickery.

The only way to meet research is to catch up with it, and the only way to catch up with it is to get a gait on; to have a good, long running start. This takes time, a long time, and energy and patience and character to deal with negative results; and above all things intelligent direction from an understanding mind. It is sheer lunacy to attempt to organize an industrial research laboratory without these exceptionally rare qualities, or even to expect results until, like KIPLING'S ship, the research organization has found itself.

With such an organization achieved, however, it is the most precious possession of an industrial establishment. It insures the future. It is evidence that the directors are not stock-jobbers who want to sell out, but rather true manufacturers who want to maintain the organization as a monument to their wisdom. That is, after all, the right and, indeed, the only way to protect stockholders. Research is more important than dividends, because it provides for them. What the pseudo-business man can not see—and by this we mean one who is a speculator, whose principal interest is to buy

and sell shares, who gets control and operates with a view to selling out—is the time factor in the sequence. Dividends follow research with such sureness that, under proper organization, one can fairly predict dividends to come by the number of men engaged at research. It is merely a matter of time, under good administration.

Art is long, but life is brief. Most of us learned this at school, with our early Latin. But science also is long. It will not work under snap judgments. It requires understanding and continuous study.

Large corporations are cumbersome, and it is difficult to make changes in them. The balance sheet does not show the reserve assets of research or the threatening liability of its lack. Without sound research in science to guide them, they are riding for a fall. Research is the plow of industry.

The Greater Vision Of Chemistry

"FOR we like sheep" we used to sing in the oratorio; "for we like sheep; like sheep have gone astray-hay-hay; like sheep have gone astray! Have gone astray!" And without doubt we have; every mother's son of us. But that is not the end of the simile. Like sheep also we follow on without much thought.

For many years we have entered into the great pasture of chemistry by the Gate of the Elements, and we think the question fair whether, in the light of present study, this is the proper portal. We miss a wonderful road by making for that entrance with all our might.

Just because we used to think the elements were the alphabets of matter we cling to the familiar expressions and bring in the dull phraseology of tradition whenever we talk about chemistry. That makes the language of chemistry dull. As proof of this, pray imagine yourself in a company of intelligent persons and the lively attention that would be paid if you were to say, "I have a story to tell of human reactions." Or if you offered to speak of a new note in architecture or of any of the fine arts. But if you commence, "Here is a chemical story," most persons will breathe a sigh of regret and hope that your discourse will not be long. Matter doesn't begin with the elements, and the elements are not eternal and everlasting, as we used to declare, although many of us were never completely convinced of it. Then why should chemistry begin with elements and acids and bases and salts? These are specifications. What the non-technical but interested public wants is a bigger picture.

The dogma that elements are eternal is discredited. It isn't so any more. It doesn't do us any good or make us better chemists to believe it. Elements are in the making in the sun and in the stars. They are in disintegration in the earth and in planets and moons. There is no sign of a beginning and no sign of an end. Elements are mere stages in the cosmic history of matter. Some are very short-lived and others long-lived, but it appears that not one of them can withstand cosmic time.

There is poetry in this vision of the great cycle of creation, if we can arouse our imagination and cease to be like sheep for a little while. True, our own lives are very short, and we sense but little of what is all around and about and beyond us. But the life of humanity is long, and our living places are in the very heart of this great and enduring life of humanity. What are we doing for it?

The Irreducible Minimum

DAILY papers last week carried more or less news about the President's message transmitting the budget. He pointed with pardonable pride to the great achievement in reducing the estimated expenditures for general and civil functions from $1,330,000,000 to $1,130,000,000. This saving of two hundred million dollars is certainly due in greatest measure to the President's own insistence upon rigid economy in all the executive and departmental activities; it has been materially helped by the recently inaugurated budget system common to all modern enterprises except government.

Expenditures for military functions remain constant at 1¼ billion dollars. Refunds and losses for the next fiscal year are estimated at 125 million less, and fixed charges have been reduced 135 million. Thus, two of the principal items responsible for the reduction in total estimated expenditures from $3,700,000,000 to $3,200,000,000 have come about by a shrinkage in our inherited obligations—the real reduction has been in the current governmental expenditures, other than for war. Certainly a reduction of 15 per cent in administrative expenses is a notable achievement. Maybe some day we can do as much to the army and navy.

But that contingency does not seem to be favored by the President. In casting about for further means of curtailing expenses he says:

"There is, however, another field of governmental operation—a rapidly broadening field of government expenditure—which may be discussed with profit to us all. I refer to expenditures which are being made from appropriations for federal aid in lines of research, improvement and development which, while having no direct connection with the operations of the business of government, have grown to become a recognized part of its activities. It is not easy, therefore, to divorce from our minds the fact that considerable of the moneys appropriated for the government are spent for those things which do not pertain to the normal functions or operations of the business of government. There is question as to how far the government should participate in these extraneous activities, and I am frank to say that an answer to the question as to whether we can look forward to any further material reduction in the expenditures of the government in future years depends largely upon whether or not there will be a curtailment or expansion of these activities."

Not wishing to indorse wasteful expenditure in any governmental activity, we cannot help but be reminded that most of the governmental activities for research, education and development are at present in crying need of funds for executing the work they have been commanded to do by the law which established them. It is a difficult if not an impossible task to segregate the cost of these operations, but as a matter of fact all of them certainly total to less than 75 million dollars. More than half of this money is spent by the Department of Agriculture in studying plant and animal diseases and in educating the farmer. Knowing how the farm bloc dies but never surrenders, the President would apparently direct the next cut in appropriations toward such activities as center in the Bureau of Standards, Bureau of Mines, the Coast and Geodetic and Geological Surveys.

What would be the result?

Two years ago, the late Dr. ROSA of the Bureau of Standards analyzed the first budget and discovered that the country was then (after two years of peace) spend-

ing a dollar for war to a penny for progress. Even then the scientific services were seriously undermanned and scandalously underpaid. Comparing the items of Dr. ROSA'S list with those from the budget ending June, 1923, and listed in the right hand column of the attached table, it is found that the current appropriations call for about the same amount of money as was spent in 1920, except only that the Bureaus of Education and Vocational Education have together been increased 6 million dollars, Farm Management 3½ million, and the Bureau of Mines ½ million.

COMPARATIVE BUDGET ESTIMATES

	1924	1923
Agricultural Experiment Stations	$1,743,600	$1,748,600
Extension and Co-operative Services	7,388,730	7,345,600
Weather Bureau	1,946,235	1,925,235
Bureau of Animal Industry (less meat inspection)	5,819,426	6,076,896
Bureau of Plant Industry	3,096,470	3,632,910
Forest Service (less receipts)	5,723,582	5,732,302
Bureau of Chemistry	1,339,031	1,277,631
Bureau of Soils	310,775	371,775
Bureau of Entomology	1,772,880	1,803,080
Biological Survey	840,625	870,565
Bureau of Standards	1,742,360	1,547,360
Coast and Geodetic Survey	2,236,015	2,213,135
Bureau of Fisheries	1,244,090	1,262,090
Bureau of Education	3,196,560	3,122,960
Geological Survey	1,576,090	1,450,940
Bureau of Mines	1,782,700	1,580,900
Howard University	283,000	190,000
Total	$42,102,169	$42,151,979

Obviously, the investigative and educational activities of the government have not been overextended in the last three years. Perhaps, in view of the great pressure which has been brought to curtail governmental activities, it should be a matter for congratulation that these budget items have not been sharply reduced. As noted in the above table, which compares the proposed expenditures for next year with those allowed for the current fiscal period, the chief governmental activities looking toward progress and improvement have so far been able to deflect the axe of the terrible General DAWES. It is now incumbent upon all of us to let our representatives understand that the present budget represents the very minimum. Most of the money now goes for overhead. For real utility the appropriations must be increased; if further decreased, they might as well be eliminated entirely.

Volume and Kind Of Business

ALL of us are interested in "How's business?" Some of us show a sordid spirit in asking the question. Others do not, but all are interested. There are innumerable trade reports, the number constantly increasing. There are the trade papers, the circulars of banks, trust companies and stock exchange houses and the studies of economic institutions, while finally the United States Government itself, through the Department of Commerce, circulates very comprehensive statements, all on the subject of "How's business?"

We are studying, or at least talking, economics at a great pace these days and we are also developing psychology. The two go together in considering the individual. Take, then, the case of the individual in connection with this matter of how is business. Judging by what one hears and sees, the common conception as to the state of business is a quantitative conception. It is a question of how much business there is. The form of speech used betrays the mental concept of quantity being the important element, for ordinarily business is not referred to as being large or small, heavy or light, but as being "good" or "bad."

Is this really the right conception from the standpoint of the individual? If business is large or active, he is moderately sure of having a job. But is having a job the *summum bonum* of the individual? Merely having a job is not so much after all. The job may be an unpleasant one. The income derived may not buy what the individual wants. Perhaps 10 years ago the income received and the market price of the things desired struck a balance, while now there is a lack of balance. Perhaps the income is doubled in 10 years, but the total cost of the things desired is trebled. Merely having a job is not sufficient.

Business can be heavy, or large or active, and therefore "good," according to the common conception, whereby each individual has a job, but without the individual being able to buy with his income what he ought to have, and without the total wealth increasing. Things may be done so inefficiently that all the work does no more than provide a mere subsistence, with no savings and therefore no advancement or progress, hence no real prosperity. It is not then a question merely of the quantity or volume of business, but also of the kind of business. Is the business of such a character that it involves improvement, advancement and progress, or is it merely working for a bare existence?

We should distinguish between merely active business and really helpful and progressive business. "How's business?" should refer not merely to quantity but also to kind or quality of business.

Industrial Management And the Buyers' Market

THOSE of our readers who are familiar with the forecasts of the Babson organization and other similar economic services, or who have put the matter to a searching personal analysis, are well aware that industry at the present time and for some period to come must encounter what is technically known as a buyers' market. That is to say, the future demands of consumers will be so hesitant, so difficult to crystallize into actual sales, and the capacity of industry to produce will so far exceed this demand that the buyer must be studied as never before and all ends must be shaped to his wishes. What is management to do to meet this condition?

As an unusual exposition of this situation and a terse analysis of the problem confronting management, the recent address of Dr. H. S. PERSON of the Taylor Society—"Shaping Management to Meet Developing Industrial Conditions"—is worthy of serious study. This paper, which will be found elsewhere in this issue, gives a particularly clear and germane view of market conditions and how management must change to meet them. Although directed to industry in general, it is of inestimable importance to the chemical and closely allied industries.

Dr. PERSON'S conclusion is more than apt, and all in executive positions, high or low, will find it a valuable subject for continual reference. What better message can be brought to industry today than this: "For a quarter century before the war even poorly managed enterprises were helped in their ascent to the heights of prosperity by the escalator of a sellers' market; now that escalator is out of commission, and the ascent to new prosperity must be achieved in the good old-fashioned way—by good management muscles, good management lungs and good management brains."

Readers' Views and Comments

Galvanic Corrosion on Yacht Sea Call

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to your issue of Nov. 15 and the letters by Mr. Hough and Mr. McKay on the subject of galvanic corrosion on the yacht Sea Call in which reference is made to some questions asked by me regarding the disintegration of the Monel yacht Sea Call, I will say that shortly after the meeting at Montreal I wrote to George Lawley, president of George Lawley & Son, Inc., builders of the Sea Call.

The following is Mr. Lawley's statement on the subject, which bears out the statement made by Mr. McKay.

Cleveland, Ohio. HENRY HOWARD.

Your letter of Oct. 11 received, and in reply would say that you have not been really and truly informed as to the trouble with the Sea Call. I think that Monel metal is a very good metal for a great many things. In the case of the Sea Call, if you remember, she was entirely plated from about one foot above the load waterline with Monel metal and the rivets we used were also Monel metal and not iron or steel. We found it impossible to obtain, after many trials, a stern post, or stem, and the architects finally informed us to use steel, which was done. As this was only a very small portion of the real surface below the waterline, and there being so much Monel metal—practically her entire body—electrolysis set up and would eat the stern post and stem very, very fast. The owner was so disgusted with the condition that he decided to break her up, which was done, as nothing could alter him in his decision. The Monel metal did not disintegrate and was not rotten. It would foul, however, in salt water very fast, a fungus-like grass would grow on that metal in 2 or 3 weeks, 4 or 5 in. long. This also disgusted the owner, as the idea was that it would not foul and that the expense of hauling out in foreign countries would be eliminated.

The steel framing of course was not affected in this case, as the water did not get to it, but the effect was so marked from action of the Monel metal that even the chain when at anchor, the tide running one way and perhaps the wind the other, was being eaten by electrolysis.

Any other information in regard to this craft I should be very glad to give you and when you are here I think you can find small samples of how it would eat steel. (Signed) GEORGE W. LAWLEY.

What Is Steel?

To the Editor of Chemical & Metallurgical Engineering

SIR:—Your simple and effective answer to the question, "What is steel?" is highly commendable. In the interest of completeness I might add that the boundary between pure iron (ferrite) and steel may be sharply drawn from metallographic observations.

Thermal analysis shows no A_1 point in pure iron-carbon alloys until the carbon content is increased over about 0.03 per cent. By way of illustration I inclose several thermal curves of such alloys having carbon contents both above and below that figure. (Fig. 1.)

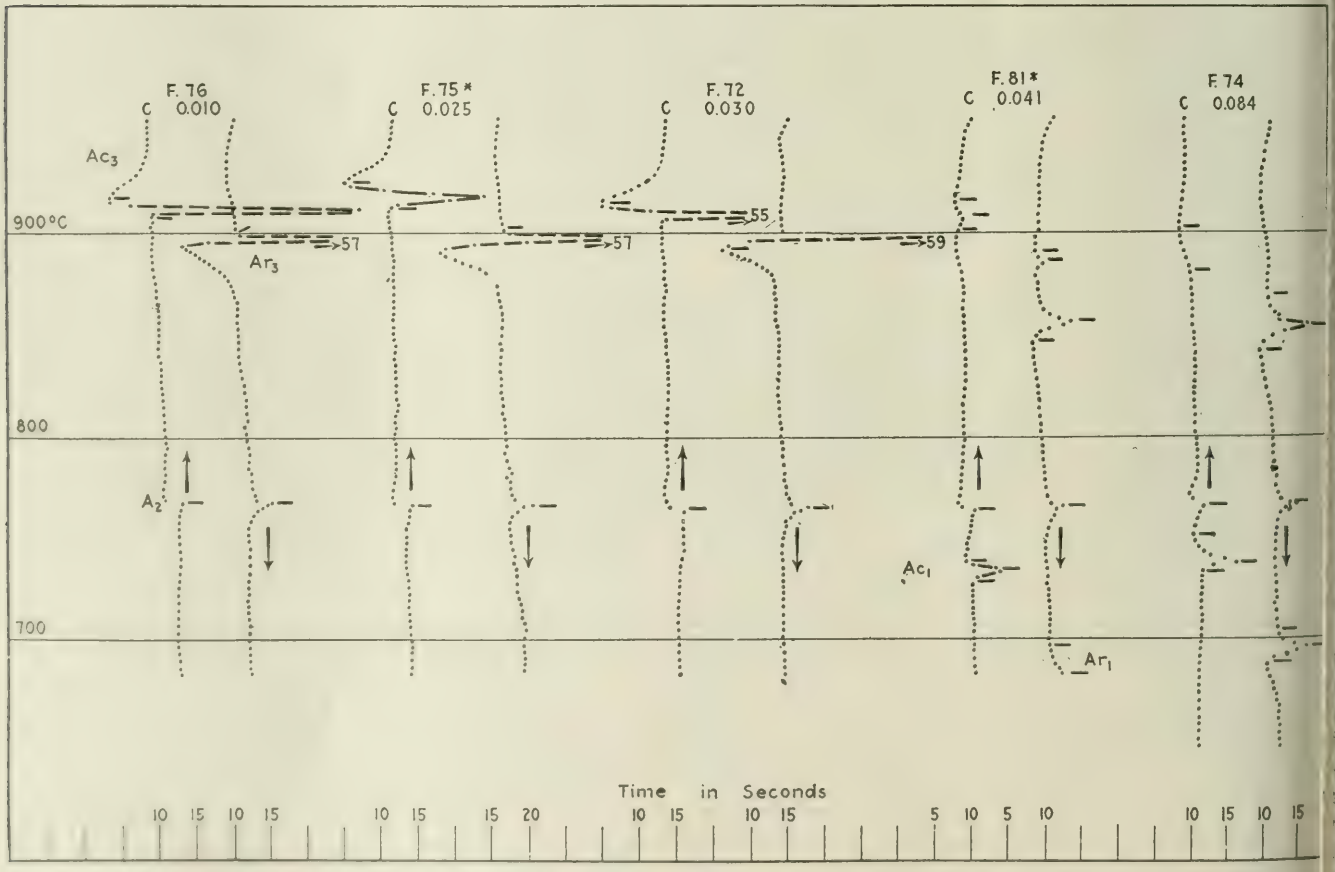

FIG. 1. HEATING AND COOLING CURVES OF VARIOUS PURE ALLOYS OF IRON WITH A SMALL AMOUNT OF CARBON

The presence of A_1 can be equally well established also by miscroscopic examination—i.e., no pearlite islands can be found when the iron contains 0.03 per cent carbon or less. It is thus evident that there exists a natural boundary between iron and steel readily fixed metallographically.

Having offered a simple and accurate definition of steel, why not do likewise for the constituents of this much abused metal? It would be quite a satisfaction for one to be able to discuss problems in heat-treatment with metallurgists without the necessity of a preliminary agreement on the meaning of the essential technical terms used.

HOWARD SCOTT,
Associate Physicist.
Bureau of Standards,
Washington, D. C.

Chemists in Public Life

To the Editor of Chemical & Metallurgical Engineering

SIR:—In connection with your editorials urging chemists to interest themselves in civic affairs it may interest you to know that the city of Stamford, Conn., has elected a chemist for Mayor. Major Phillips, of the Phillips Chemical Co., manufacturer of milk of magnesia, is an active member of the Stamford Chemical Society. He was elected Mayor on the Democratic ticket by a large majority in a city which is normally overwhelmingly Republican.

Our Stamford Chemical Society at its October meeting arranged a program dealing with problems of garbage and sewage disposal, which have become very acute in our community. The members of the city administration and the opposing candidates for the Mayoralty were specially invited guests and took part in the discussion.

R. H. STEVENS,
President.
Stamford, Conn.

Metallurgical Education

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read your editorial on Metallurgical Education in the issue for Nov. 22 with much interest as well as Dr. Little's report on Chemical Engineering Education which has just appeared.

Your description of the evolution of a new course in Metallurgical Engineering is probably not overdrawn as representing its first stage in some instances, but this stage is usually transient if sufficient funds are available for expansion. Almost any new course, especially where apparatus is involved, requires a large capital investment at the start. Tremendous capital has been required in recent years to take care of the enormous increase in students entering our schools as well as for the evolution of new courses. This achievement is indeed a convincing proof of our wonderful response to educational needs. The advance in primary and secondary school work has been scarcely less astonishing. I am very much inclined to think that our personnel for "white collar jobs" is in danger of growing too large while our personnel for the ordinary workaday jobs is decreasing in numbers and in efficiency.

I do not believe in standardized courses, because the needs of one locality are different from those of any other locality. We should rather try to fit men for locally important industrial needs. The few who do not fit into this scheme will be able to suit themselves at some other locality without great hardship. Our work must be intensive to be really effective. But the best result in product comes through the careful selection of the teachers. Personal traits in the teacher have far more to do with the result than a good curriculum. Mr. Dow's letter shows that he still feels keenly the effects of Dr. E. W. Morley's wonderful personality. We have a great many such teachers giving their all in this service unselfishly, and the attempt to substitute anything else must meet with failure.

The beginner in my time had only to make the acquaintance of atoms and molecules; now we have electrons, ions, atoms, molecules, crystal aggregates, colloids. The capacity of the student has not greatly increased. If we do not decrease the surface covered and invent better teaching methods, he must inevitably contract mental indigestion. One of the crying troubles of most teachers is their inability to imagine themselves in the position of the student. They forget that it has required years of training to acquire what seems now so simple, and they constantly shoot far over the head of the beginner, to his stupefaction and dismay.

EDWARD HART.
Lafayette College,
Easton, Pa.

Polish Chemical Industries

THE chemical industry connected with agriculture was already very far advanced in Poland before the war, for it constituted one of the sources of her great wealth; it should soon not only return to its former height of development but also make further progress. The status of the chemical industry in that country is described in an article in *Poland*, for October, 1922.

Sugar constitutes the most important branch of this industry, especially in Poznania and Congress Poland —the pre-war output amounted to about 700,000 tons. Many sugar factories were destroyed during the war, especially in Congress Poland, and the present production is only about one-third of the output produced previous to the war.

FOOD PRODUCTS

The united provinces of Poland form the chief European center for the culture of potatoes. The chemical industry which is dependent upon this product, such as alcohol, starch and sirup, is highly developed. The industry of drying potatoes (flaked potatoes) is carried on to a great extent in Poznania.

The brewing and malt industry of Poland is advancing rapidly; the species of barley grown there is of superior quality and a considerable quantity of hops is cultivated in Congress Poland and Volhynia.

During the last few years before the war the milk factories of Congress Poland and Poznania were largely employed in manufacturing technical byproducts of milk.

The manufacture of the byproducts of fruit and vegetables (jams, preserved fruit) was very insignificant, whereas the manufacture of the byproducts of sugar (cocoa, chocolate, sweetmeats) attained considerable importance in Congress Poland.

There are several large factories employed in producing soap, candles and glycerine, and in extracting fats. Today the outlook is more hopeful for this special branch.

CHIEF INORGANIC CHEMICAL INDUSTRIES

Sulphuric acid is produced in large quantities and very cheaply in Upper Silesia, as it is the refuse obtained when smelting zinc ore, and as a result of the importation of pyrites from Spain, Congress Poland has also been enabled to produce a considerable quan-

tity. Besides the Upper Silesian factories, there are also many large sulphuric acid and "oleum" works active in Congress Poland, Malopolska (Galicia) and Wielkopolska (Poznania).

Kitchen salt and brine are found in large quantities in certain districts of Poland. This is of great value to the future development of this branch of chemical industry which produces soda (common and caustic), muriatic acid, chlorine, bleaching lime, etc.

A great quantity of ammonium sulphate and cyanide of lime is produced from nitrogenous compounds in Upper Silesia and by the oxidation of synthetic ammonia.

Salts of potassium, which are in great demand both for artificial manure and in chemical industry, are to be found at Kalusz. Bertolet salts are manufactured in several factories and potassium nitrate is manufactured at Bory, near Krakow. Poland has yet another means of obtaining salts of potassium—viz., from the wash from molasses distilleries. Before the war several factories in Congress Poland were employed in producing carbonate of potassium from distillers' wash and potash from the strontium lye which is obtained when refining molasses.

Superphosphates are produced in valuable quantities in a number of factories in Congress Poland, Wielkopolska and Upper Silesia. This special line of chemical industry was ruined in Congress Poland during the war, but it is now beginning to revive again.

Dyestuffs are produced in several large factories and in many small ones. Salts of aluminum—i.e., sulphate of aluminum and other less important mineral products—are manufactured in several factories in Congress Poland.

Chief Organic Industries

During the last few years before the war Poland produced about one million tons of petroleum per annum. The industry of distilling rock-oil in order to obtain motor spirit, petroleum, lubricating oil, paraffine, petroleum asphalt and coke, has made rapid strides, although a fair quantity of crude oil is exported to other countries.

Since there is a lack of coke-producing coal in Congress Poland and Malopolska, the coke industry does not exist in these provinces, but it is exceedingly well developed in Upper and Cieszyn Silesia. Coal pitch, which is a residue from the gas and coke ovens, is distilled in order to obtain aromatic carbohydrogens, phenol, various oils and pitch; but this industry is extensively carried on only in Upper Silesia.

In spite of the abundance of raw materials, the dry distillation of lignite and turf is scarcely known in Poland, though it is an industry which would be of great advantage to the country. In view of the great extent of forest ground in Poland, the dry distillation of wood will doubtless become a very valuable industry. Before the war it attained extraordinary proportions in a primitive form. At the time of the war Poland started to manufacture pitch, turpentine and resin from the waste matter of pines which results from the felling of the same.

The manufacture of the so-called intermediate products of the synthetic organic industry, such as the mass-production of aromatic nitro-compounds (nitrobenzol, etc), amines, aniline, sulphuric acids, etc., was not very extensive in Poland before the war, except to a certain degree in Upper Silesia. Today, especially after the annexation of Upper Silesia, the needs of the country enforce a greater interest in the corresponding branches of the industries connected with the manufacture of colors, explosive materials, etc. The synthetic-organic industry, in particular the manufacture of colors, has made great progress in Poland, especially in Congress Poland, where there was a wide market for it. Today there is every prospect of further development, particularly after the annexation of Upper Silesia, for this latter province supplies Poland with a large quantity of raw material.

For obvious reasons, the manufacture of explosives was practically an unknown factor in Poland before the war. Now, however, it is being speedily organized, and in the near future Poland will no doubt be in a state to supply her own demands in this respect.

Other Chemical Industries

Before the war, tanning was a most important branch of industry in Poland, especially in Congress Poland, where it was technically in a flourishing condition. Several large factories in Congress Poland are employed in the production of tanning extracts. Nearly all the raw materials are supplied by foreign countries, partly by the Ukraine, but principally by North America.

The production of vegetable and animal fibers and subsequently bleaching, dyeing, printing and the finishing process of tissues and yarns is an important branch of chemical industry in Poland. The factories are well equipped technically. Congress Poland also possesses two artificial silk factories. Factories for the manufacture of rubber and celluloid and their byproducts, as well as other artificial plastic masses, are almost unknown quantities in Poland—a lack in Polish industry which will no doubt be rectified in the near future.

Manufacture of Essential Oils in 1921

The Department of Commerce announces that the census reports show a considerable decrease in the activities of the establishments engaged primarily in the manufacture of essential oils (not including synthetic or artificial oils) during 1921, as compared with the year 1919. The total value of products reported amounted to $3,271,120 in 1921, and to $5,698,403 in 1919, a decrease of 42.6 per cent.

Detailed statistics for the years 1921 and 1919 are given in the following table:

Products		1921	1919	Per Cent of Decrease
Total value of products		$3,271,120	$5,698,404	42.6
Oil of:				
Peppermint†,	pounds	152,134	236,233	35.6
	value	$368,353	$1,276,136	71.1
Spearmint‡,	pounds	99,056	29,985	*230.4
	value	$356,274	$145,709	*144.5
Cloves,	pounds	199,200		
	value	$335,376		
Nutmeg,	pounds	19,795		
	value	$21,939	$2,950,961	45.0
Sandalwood,	pounds	23,835		
	value	$178,968		
Other oils,	value	$1,086,507		
Witch-hazel extract,	gallons	(§)	510,110	
	value	(§)	$448,938	
All other products,	value	$923,703	$876,660	30.3

* Increase.
† Crude and refined are combined to avoid disclosure of operations of individual establishments.
‡ Crude only. No refined spearmint reported in 1921 or 1919.
§ Included in all other products to avoid disclosure of operations of individual establishments.

The returns indicate that the combined output of all establishments was approximately 56 per cent of the maximum capacity based upon a demand requiring full running time.

A Discussion of the Organization and Functions of the Bureau, Types of Standards Investigated, Funds, Personnel and Methods—Relation of Industrial Research and Technical Work to Fundamental Studies of Constants and Research in Pure Physics

By R. S. McBride
Assistant Editor, *Chemical & Metallurgical Engineering*

THE National Bureau of Standards, which was established in 1901 for the service of science and industry, has become the greatest physical laboratory in the world. At this time the organization and work of the bureau are of particular interest because of the change in directorship incident to the resignation of Dr. S. W. Stratton. The question has naturally been raised whether the new director, who has not yet been designated, will continue the work at the bureau along existing lines or will tend to divert it into new or different channels. For a clear understanding of any such problem, the present scope, organization and activities of the bureau must be considered.

Five Types of Standards

Probably the idea of standards suggests to nine out of ten persons matters of weight or measurement. As a matter of fact the "standards of measurement," to which the bureau gives much attention, form only one of five groups of standards to be considered. Standard constants, standards of quality, including specifications for materials of all sorts, standards of performance for machines or devices, and standards of practice, including codes of regulatory laws of a technical sort, also come under the attention of this institution.

These five types of standards have been outlined and the purpose of each has been shown clearly in a function chart published by the bureau, which is reproduced herewith. This brings out clearly the relationship of the different kinds of work to the fundamental function of the bureau—namely, "development, construction, custody and maintenance of reference and working standards and their intercomparison, improvement and application in science, engineering, industry, and commerce."

Internal Organization

Because of its location, the Bureau of Standards has been organized to function almost independently of the rest of the Department of Commerce. This has necessitated complete mechanical and clerical organization, in addition to the scientific divisions of the bureau. The interrelation of these parts is shown on the organization chart, from which it can be seen that the scientific work of the bureau has been divided primarily into divisions of physics—heat, light, electricity and other branches. More recently there have been added divisions to deal with problems of particular industries such as the problems of physical metallurgy and of scientific ceramic manufacture. Problems of structural engineering and miscellaneous engineering materials are grouped together in another division for convenience of administration.

The special activities of the bureau which have been added since Mr. Hoover became Secretary of Commerce are in special groups dealing with problems of building and housing, simplified commercial practice and trade specifications that work closely with the Department of Commerce and less intimately with the research divisions that have hitherto formed substantially all of the bureau.

This type of organization has been intended to bring together under a single division chief the varieties of research and investigation requiring common methods for their study. Thus men having particular ac-

quaintance with methods of temperature measurement and research on thermal chemistry or thermal physics are engaged on problems applicable in many industries. Thermometer calibration, pyrometer development, heat conductivity of building materials, thermal properties of substances used in the refrigerating industry, the properties of refractories at high temperature, and many other subjects and commodities are thus considered in the heat division of the bureau. Other phases of investigations on the same commodities are often going on simultaneously in different divisions, especially where electrical properties, chemical properties or optical properties of the materials are involved. Only in the case of a limited number of industrial products having large importance from the standpoint of the government have separate sections been organized along commodity lines.

This type of staff organization has followed somewhat the lines which determine college organization. In fact in many respects the Bureau of Standards resembles closely a graduate institution where the scientific staff is engaged upon researches of greater difficulty and complexity, but otherwise similar to those done by the graduate students and teaching staff of any university.

Personnel and Appropriations

The Bureau of Standards was founded in 1901 with a total personnel of twenty-three, of whom fourteen were members of the scientific staff and nine of the non-scientific. From that small beginning, which was virtually only a weights and measures office, the bureau grew to a personnel of 1,150 at the end of the war period. However, much of the war-time growth was not of a sort that could be expected to continue, and at present the scientific staff consists of approximately 550 persons supplemented and assisted by 335 non-scientific staff employees. The growth in personnel is brought out most clearly by the graphical presentation of data given herewith.

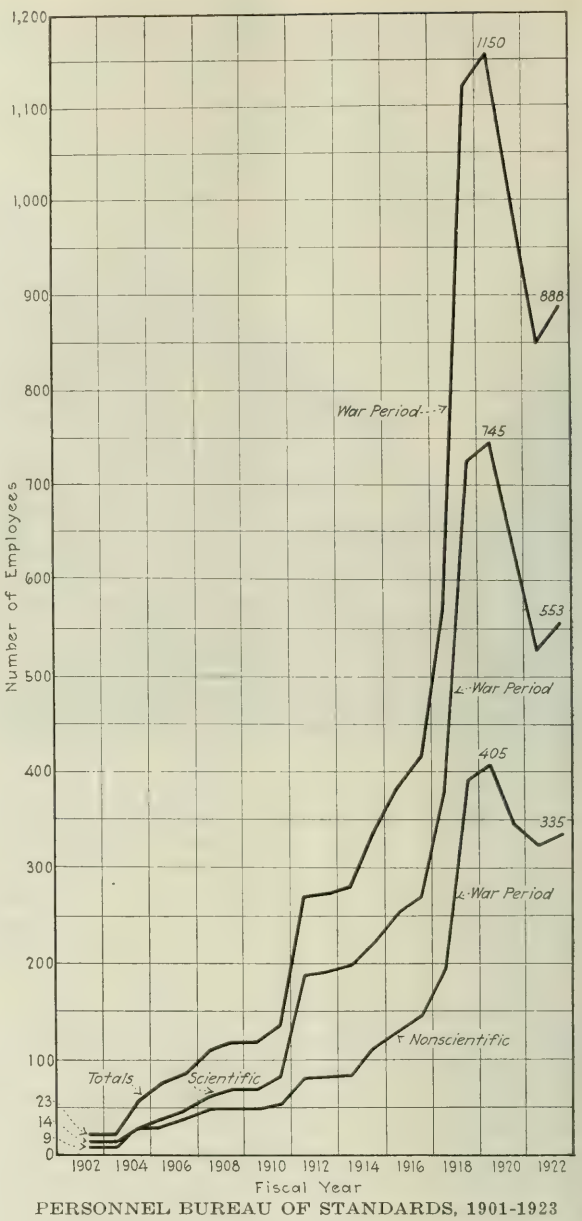
The scale of salaries paid to the scientific staff during the early history of the bureau was comparable with or slightly better than the college and university salaries of the country. However, during recent years the bureau has experienced great difficulty in getting the most desirable type of men to leave other positions and come to Washington, because the financial conditions were anything but attractive to them. The maximum salary paid is, of course, for the director, $6,000 per year; and the salaries scale down from this to about $1,500 as the average entrance salary for scientific and technical men. A large majority of the staff receives between $1,000 and $3,000 per year, only about 15 per cent of the total number being paid $3,000 or higher. When one realizes that the organization is almost altogether a research organization, the complication this limitation produces is evident.

APPROXIMATE TOTAL EXPENDITURES

Bureau of Standards
Fiscal Years 1902 to 1922

1902	$165,000	1913	$680,000
1903	145,000	1914	625,000
1904	340,000	1915	685,000
1905	170,000	1916	730,000
1906	170,000	1917	950,000
1907	170,000	1918	2,990,000
1908	185,000	1919	3,360,000
1909	245,000	1920	1,890,000
1910	426,000	1921*	1,319,000
1911	170,000	1922	1,507,000
1912	566,000		

*Excluding funds transferred from other departments.



PERSONNEL BUREAU OF STANDARDS, 1901-1923

The growth in appropriations has been about parallel to the growth in personnel. The approximate total expenditures of the bureau during its first 21 years are given in the accompanying tabulation. Of this total expenditure, slightly more than half has been for salaries, the remainder representing expenditures for apparatus and equipment, travel, and the multitude of operating expenses which any institution of such size occupying a group of twenty-four buildings is bound to incur.

Of the total expenditure during its life a large sum has gone for permanent buildings and grounds. Probably five or six million dollars is now so invested.

Of the expenditures since 1910 a very large proportion has been from appropriations granted as "special funds," which are sums of money given for the conduct of specific lines of work with no limitation as to the percentage for salaries, equipment, travel or other subdivision of the work. The influence of these special funds on the rate of increase in number of employees and total expenditure is evident from the curves and tables of data. At present a very large part of the total money is appropriated in this way.

Although established primarily as a bureau of phy-

THE OFFICE

Chief

FUNCTION: TO SUPERVISE THE UNITS OF THE ADMINISTRATIVE BRANCH, TO SELECT PERSONNEL AND REMOVE OFFICE PERSONNEL, TO PLAN CLERICAL ROUTINE, TO SUPERVISE EDITORIAL COMMITTEE WORK

PERSONNEL 3 PAYROLL $6,280

FINANCE SECTION

FUNCTION: TO KEEP CONTROLLING ACCOUNTS OF FUNDS, TO PREPARE FINANCIAL STATEMENTS AND ESTIMATES, TO AUDIT VOUCHERS, PREPARE BILLS, RECEIVE FEES AND PREPARE PAYROLLS, TO PERFORM ADMINISTRATIVE ROUTINE RELATING TO TEST RECORDS

PERSONNEL 11 PAYROLL $16,020

PERSONNEL SECTION

FUNCTION: TO PROCURE, INTERVIEW AND EXAMINE CANDIDATES FOR APPOINTMENT, TO RECOMMEND THE APPOINTMENT, PROMOTION, TRANSFER OR DISCHARGE OF PERSONNEL, TO MAINTAIN PERSONNEL RECORDS, TO DRAFT CHARTS AND GRAPHS

PERSONNEL 6 PAYROLL $9,040

PUBLICATION SECTION

FUNCTION: TO ASSIST IN EDITING MANUSCRIPT FOR PRINTER, TO PREPARE REQUISITIONS FOR PRINTING AND BINDING, TO RECEIVE, STORE AND ISSUE PUBLICATIONS, TO MAINTAIN MAILING LISTS

PERSONNEL 3 PAYROLL $3,100

PROPERTY, STORES & TRANSPORTATION SECTION

FUNCTION: TO STORE, RECORD AND ISSUE SUPPLIES, MATERIALS AND EQUIPMENT, TO KEEP PROPERTY RECORDS, TO MAINTAIN AND OPERATE ALL MOTOR VEHICLES

PERSONNEL 14 PAYROLL $14,500

MAIL AND FILES SECTION

FUNCTION: TO RECEIVE, INDEX AND ROUTE ALL INCOMING AND OUTGOING MAIL, TO MAINTAIN CORRESPONDENCE FILES, TO MAINTAIN TELEPHONE AND ELEVATOR SERVICES

PERSONNEL 24 PAYROLL $17,900

LIBRARY

FUNCTION: TO MAINTAIN BUREAU'S LIBRARY, TO RECEIVE, CATALOGUE AND CIRCULATE INCOMING PERIODICALS, TO COMPILE BIBLIOGRAPHIES, REFERENCE LISTS AND TRANSLATIONS

PERSONNEL 2 PAYROLL $2,600

PURCHASE SECTION

FUNCTION: TO PREPARE CONTRACTS FOR PROCUREMENT, LEASING OR PURCHASE OF SUPPLIES, REAL ESTATE, EQUIPMENT & SERVICES, AND APPROVE PAYMENTS, TO RECEIVE BIDS AND TENDERS, TO SECURE CONTRACT PERFORMANCE

PERSONNEL 4 PAYROLL $5,000

INFORMATION SECTION

FUNCTION: TO REVISE, WRITE AND DISTRIBUTE FORMS, TO PREPARE REPORTS, TO MAINTAIN INFORMATION SERVICE FOR BUREAU, TO RECEIVE AND STORE, TO PREPARE AND DISTRIBUTE THE MONTHLY TECHNICAL NEWS BULLETIN

PERSONNEL 2 PAYROLL $3,800

SCIENTIFIC BRANCH

WEIGHTS AND MEASURES DIVISION

Chief

FUNCTION: TO PREPARE SPECIFICATIONS AND TOLERANCES FOR USE IN STANDARDIZING MODELS AND MEASURES, TO DESIGN, IMPROVE AND CONSTRUCT WEIGHING AND MEASURING APPARATUS TO RECORD STANDARD LENGTH, MASS, TIME, AREA, VOLUME, DENSITY AND PRESSURE, TO TEST AND CALIBRATE WEIGHTS AND MEASURES APPARATUS BY COMPARISON WITH GOVERNMENT REFERENCE STANDARDS, TO CONDUCT RESEARCH TO ASCERTAIN PHYSICAL CONSTANTS MORE ACCURATELY, TO COOPERATE WITH STATE AND LOCAL GOVERNMENT AUTHORITIES IN THE PREPARATION AND ADMINISTRATION OF LAWS REGULATING WEIGHTS AND MEASUREMENTS

PERSONNEL 58 PAYROLL $101,260

- LENGTH SECTION
- MASS SECTION
- TIME SECTION
- CAPACITY & DENSITY SECTION
- THERMAL EXPANSIVITY SECTION
- GAS MEASURING INSTRUMENTS SECTION
- WEIGHTS AND MEASURES LAWS ADMINISTRATION SECTION
- COMMERCIAL SCALES SECTION
- GAUGES SECTION

HEAT AND THERMOMETRY DIVISION

Chief

FUNCTION: TO ESTABLISH STANDARD SCALES OF TEMPERATURE THROUGHOUT THE RANGE OF MEASURABLE TEMPERATURES, TO DEVISE AND IMPROVE SPECIFICATIONS AND METHODS OF STANDARDIZING TEMPERATURE MEASURING INSTRUMENTS, TO DESIGN, IMPROVE, AND CONSTRUCT STANDARD TEMPERATURE MEASURING INSTRUMENTS TO DETERMINE THE PHYSICAL CONSTANTS OF MATERIALS SUCH AS SPECIFIC AND LATENT HEATS, RATES OF REACTION AND CONDUCTION, MELTING AND FREEZING POINTS AND HEAT TRANSMISSION, TO DEVISE APPARATUS FOR AND CONDUCT FIRE TESTS OF STRUCTURAL MATERIALS, TO DETERMINE FUNDAMENTAL ENGINEERING DATA INVOLVING THERMAL CONSTANTS, TO INVESTIGATE PROBLEMS OF AND TEST AUTOMOTIVE POWER PLANTS, FUELS AND LUBRICANTS

PERSONNEL 72 PAYROLL $124,980

- THERMOMETRY SECTION
- PYROMETRY SECTION
- HEAT MEASUREMENTS SECTION
- LOW TEMPERATURE SECTION
- FIRE-RESISTANCE SECTION
- AUTOMOTIVE POWER PLANTS SECTION

OPTICS DIVISION

Chief

FUNCTION: TO DESIGN AND CONSTRUCT APPARATUS FOR MAKING SPECTROSCOPIC, POLARIMETRIC, COLORIMETRIC AND RADIOMETRIC ANALYSIS OF PROPERTIES OF MATERIALS; TO DETERMINE THE SPECTRAL TRANSMISSIVITY AND REFLECTIVITY AND THE EMISSIVE AND ABSORPTIVE PROPERTIES OF MATERIALS, TO TEST SUGAR AND SUGAR PRODUCTS, THE REFRACTIVE INDICES OF OPTICAL WATER GLASS, PHOTOGRAPHIC PLATES AND FILMS, OPTICAL MATERIALS, FINE WIRES, WATER SPRAYS, POISON GAS AND BIOLOGICAL FLUIDS; TO STANDARDIZE THE DESIGN AND PERFORMANCE OF OPTICAL INSTRUMENTS, PRECISION BALANCES, CAMERAS, AND SEARCH-LIGHT APPARATUS; TO ASSIST THE GOVERNMENT SERVICE IN THE MAINTENANCE AND OPERATION OF ITS SUGAR LABORATORIES

PERSONNEL 39 PAYROLL $76,700

- SPECTROSCOPY SECTION
- POLARIMETRY SECTION
- COLORIMETRY SECTION
- OPTICAL INSTRUMENTS SECTION
- RADIOMETRY SECTION
- DISPERSION PHYSICS SECTION
- INTERFEROMETRY SECTION

CHEMISTRY DIVISION

Chief

FUNCTION: TO DEVISE METHODS AND APPARATUS FOR ANALYZING AND TESTING MATERIALS; TO MAKE CHEMICAL ANALYSES TO DETERMINE THE COMPOSITION AND PURITY OF MATERIALS UNDER TEST, TO DETERMINE SPECIFICATIONS AND THE PHYSICAL CONSTANTS OF TECHNICAL MATERIALS, TO PREPARE PURE MATERIALS FOR STANDARDIZATION WORK

PERSONNEL 67 PAYROLL $128,660

- PHYSICAL CHEMISTRY SECTION
- ELECTROCHEMISTRY SECTION
- GAS CHEMISTRY SECTION
- REAGENTS AND APPARATUS SECTION

sics and physical research, the Bureau of Standards has always included a considerable number of chemists and engineers. In fact the chemical division of the bureau has been one of the largest, including during recent years a total personnel of approximately one hundred. The number of engineers on the staff has also grown in proportion as the technical activities of the bureau have increased. It is the relation of these technical problems to the fundamental studies in physics that have made it difficult for many to understand the work of the bureau.

In the beginning the bureau gave practically all its time to studies of weights and measures and fundamental problems in heat, light, electricity or mechanics that one commonly associates with a physical laboratory. However, the application of such studies to the practices of engineering and industry was always an important part of the motive behind the work; and with increasing knowledge, the bureau acquired increasing contact with those active in industrial lines. More and more commercial laboratory men came to the bureau for information and more and more other government departments referred to it the problems of tests and purchases.

With the transfer to the Bureau of Standards of part of the Technologic Branch of the U. S. Geological Survey and later of the Contracts Laboratory of the Bureau of Chemistry, the Bureau of Standards was made in effect a supervisor of purchases for the government in so far as standards or specifications were involved. This did not make compulsory the reference of such problems to the bureau, but it did make available to other government institutions the advisory services of the bureau in such a way that many thousands of tests for other government institutions are now made annually. In fact, during recent years the number of tests performed for the government and outside agencies has exceeded 100,000 per year.

In order to do this testing work most intelligently and fairly to all, the bureau made a study of industrial processes and products; and after the investigators became familiar with these subjects, publications of a technical nature were issued from time to time. Thus there grew up the basis upon which the bureau has now built what is in effect a "Bureau of Technology" closely interwoven with, and in some measure superseding parts of, the original "Bureau of Physics."

It is practically impossible to generalize as to the advantages and disadvantages of this technologic work at the bureau. Circumstances in each of the fifty or sixty divisions are so different that any generalization is bound to be wrong in the case of many of the commodities or the branches of physics or chemistry which are represented. It is safe to say, however, that the new director, whoever he may be, will have confronting him one general problem that can never be wholly settled—namely, To what extent can the bureau take up practical engineering and technical studies, and to what extent must it confine its effort to the problems of so-called "pure science"? It is, of course, out of place in this article to undertake any recommendation on this point; but it may be profitable to point out by typical examples some of the important factors involved in any plan for the work of this great institution.

Standard Specifications

The United States Government is one of the greatest purchasers in the world. Naturally the maximum efficiency in purchasing is desirable not only for the sake of economy but also as an example to the individual and to business. As pointed out earlier in this article, many of the government purchases have been super-

vised by tests made at the Bureau of Standards. However, this scheme did not procure general uniformity of purchasing and more recently there has been established the Federal Specifications Board, of which the director of the Bureau of Standards is chairman. This board arranges for the adoption of uniform specifications for purchases by all of the departments of the government, in so far as the requirements of the government are such as to make the adoption of specifications worth while.

Many of these specifications, though adopted primarily for government use, will undoubtedly have general influence upon trade practices of the country. In the past there have been many such cases where the government adopted for commodities such requirements as were recommended by the Bureau of Standards and thereby established a trade custom that enabled all purchasers of such commodities to get first-quality product. One of the most conspicuous examples of success has been the standard specifications for incandescent electric lamps adopted first more than 10 years ago. Now it is possible to get anywhere electric lamps in conformity with the latest government standards. Indeed these standards are almost of universal effect. This is possible, as they are invariably adopted with the co-operation and assistance of the most forward-looking scientists and engineers in industry and not by any academic consideration of theory considered alone by the government investigators.

In many respects this work on standard specifications at the bureau has been a pioneer effort, for often those industries that previously had not considered any specifications or requirements for their product now realize the industrial advantage to the producer of having well-established, reasonable and enforceable requirements of this sort. The impartial judicial position which the Bureau of Standards can take in such work has lent great dignity to its efforts and has perhaps contributed most of any single factor to such success as has been attained.

Standards of Performance

Just as standard specifications for commodities are desirable, so too are standards of performance for machines and devices. It is quite as important to know how to rate a machine and what tests can reasonably be applied to determine performance as it is to specify the composition, heat-treatment, size or other characteristic of any commodity or of any part of the machine or device. The relation of the Bureau of Standards to such work has not been limited to tests or performance requirements on government purchases alone, but it has been to a considerable extent so directed. Purchase of motors, fans and other small electrical devices according to performance tests made at the bureau has been one good illustration of how this effort has been worked out. More recently work of a similar sort on dry cells and storage batteries has been carried through to the adoption of generally acceptable standards of performance for such equipment.

Standards of Practice

In the case of standards of practice, the work of the bureau has been limited largely to studies on public utility practice and safety standards. Codes and regulations involving technical detail work demanded

---

Functions of the National Bureau of Standards

Development, construction, custody and maintenance of reference and working standards and their intercomparison, improvement and application in science, engineering, industry and commerce.

Standards of Measurement:

To aid accuracy in industry through uniform and correct measures;

To assist commerce in size standardization of containers and products;

To promote justice in daily trade through systematic inspection and regulation;

To facilitate precision in science and technologic research through calibration of units, measures, and instruments involved.

By standards of measurement is meant:

Reference and working standards for measurements of all kinds, including fundamental and derived standards of measurement for expressing the quantitative aspects of space, time, matter, energy and motion, and of their interrelations. By definition, specification, or material standard, covering, for example, length, area and volume; mass, weight, density and pressure; heat, light, electricity and radioactivity, including for each the quantity, flux, intensity, density, etc.

Standard Constants:

To serve as an exact basis for scientific study, experiment, computation and design;

To furnish an efficient control for industrial processes in securing reproducible and uniformly high quality in output;

To secure uniformity of practice in graduating measuring instruments, or in compiling tables for standards of quality and performance, and wherever such uniformity is desirable;

To aid laboratory research by reducing errors and uncertainty caused by use of data of doubtful accuracy.

Standard constants are defined as:

Natural standards or the measured numerical data as to materials and energy, known as physical or standard constants, i.e., the fixed points or quantities which underlie research and industrial processes when scientifically organized. Mechanical equivalent of heat, light, electricity and gravitation; specific densities; viscosities; melting and boiling points; heat capacity; heats of combustion; velocity of propagation of light; conductivities of materials to heat and light; electrochemical and atomic weights; and many similar magnitudes determined experimentally with maximum precision and referred to fundamental standards of measure.

Standards of Quality:

To secure high utility in the products of industry by setting an attainable standard of quality;

To furnish a scientific basis for fair dealing to avoid disputes or settle differences;

To promote truthful branding and advertising by suitable standards and methods of test;

To promote precision and avoid waste in science and industry by affording quality standards by which materials may be made, sold and tested.

Standards of quality comprise:

Specifications for material (by description, sample, or both), known as standards of quality, fixing in measurable terms a property or group of properties which determine the quality. The numerical magnitude of each constituent property pertinent to the quality involved, and specific magnitude in units of measure of such significant factors as uniformity, composition, form, structure and others.

Standards of Performance:

To clarify the understanding between maker and user as to operative efficiency of appliances and machines;

To make exact knowledge the basis of the buyer's choice;

To stimulate and measure mechanical progress.

Standards of performance include:

Specification of operative efficiency or action for machines and devices, known as standards of performance, specifying the factors involved in terms susceptible of measurement. Numerical statement of speed, uniformity, output, economy, durability and other factors which together define the net efficiency of an appliance or machine.

Standards of Practice:

To furnish for each utility a single impersonal standard of practice as a basis for agreement of all interests, clearly defined in measurable terms;

To insure effective design and installation of utilities;

To promote safety, efficiency, and convenience in the maintenance and operation of such utilities;

To secure uniformity of practice where such is practicable, and effective alternates in other cases.

Standards of practice are defined as:

Codes and regulations impartially analyzed and formulated after study and experiment into standards of practice for technical regulation of construction, installation, and operation, and based upon standards of measurement, quality, and performance. Collation of standard data, numerical magnitudes, and ranges of the pertinent factors defining quality, safety, economy, convenience and efficiency.

thorough technical consideration in advance of adoption if they are to be fair and effective. In some cases uniformity of practice is of great importance, and in any such case the work of the bureau is of particular value because of its national character. However, in most cases the work of this sort is limited to an advisory or consulting function regarding matters of scientific fact. Regulatory measures which are matters of opinion are, or should be, in the hands of state and city authorities or intrusted to other government departments. As a matter of fact, the Bureau of Standards has substantially no work of a supervisory or administrative nature. Its whole organization is based on the assumption that it will not have any such police powers, even with respect to matters of fundamental standards of weight and measure, much less with respect to any other matters of science, technology or industry.

Growth of Industrial Research

The adoption of standard specifications, the determination of standard constants and other work on industrial materials have naturally led to an interest in industrial research. In some lines the bureau has found that industry was wholly unable to supply it with information regarding industrial processes in relation to composition or quality of the product sold. This led to a desire for a study of the industrial processes themselves; and the bureau has installed textile, paper, rubber, glass and ceramic equipment that makes its large industrial laboratory virtually a small-scale industrial city. To a considerable extent this work has been done with funds furnished by Congress for specific purposes. For example, one fund of this sort was specifically provided for the investigation of textiles, another for the investigation of optical glass, a third for the study of clay products, and several others of more general significance for industrial research, metallurgical research, etc.

In many cases the bureau has been encouraged by the members of industrial establishments to carry out this small-scale commercial, industrial research. In other cases there has been some criticism of the bureau for this work. This criticism has apparently been based largely upon the claim that the bureau should do nothing of this sort which industry can do for itself, but should limit its efforts to fundamental studies of science, either pure or applied, which are of interest to many industries or to all parts of an industry that cannot afford to carry out this work without government aid.

There is no doubt that the industrial work of the bureau has been more conspicuous and for many reasons more attractive to many of the members of the technical and scientific staff. Naturally this type of work is best appreciated by Congressmen, and thus encourages Congress to grant appropriations for subsequent work. Probably for this reason there has been a marked increase in this type of study, which began to be noticeable during several years preceding the war. However, it has been felt that in some cases the tendency has gone so far as to supersede fundamental scientific studies with so-called "practical" or technical investigations. Where this has occurred, there has been ample ground for the objection raised by those who no longer could get from the bureau the expected assistance on *fundamental* scientific work which that institution alone can do to best advantage in some cases.

Aluminum Products in 1921

The Department of Commerce announces that the census reports show a considerable decrease in the activities of the establishments engaged in the manufacture of aluminum products during the year 1921 as compared with 1919. The total value of products reported for 1921 amounted to $45,822,000, and for 1919 to $75,278,000, a decrease of 39.1 per cent. An additional production amounting to $1,847,000 in 1919 was reported by establishments engaged primarily in the manufacture of other products, principally brass, bronze and copper products. Corresponding figures for 1921 are not available.

The returns indicate that the combined output of all establishments was approximately 50 per cent of the maximum capacity, based upon a demand requiring full running time.

The statistics for 1921 and 1919 are summarized in the following statement:

COMPARATIVE SUMMARY OF STATISTICS FOR ALUMINUM MANUFACTURES, 1921 AND 1919

	1921*	1919*	Per Cent of Decrease†
Number of establishments	87	83	....
Persons engaged in manufactures	11,018	13,257	96.1
Proprietors and firm members	36	34	....
Salaried employees	1,398	1,821	23.2
Wage earners (average number)	9,584	11,402	15.9
Salary and wage payments	$13,945,000	$16,634,000	16.2
Salaries	3,110,000	3,307,000	6.0
Wages	10,835,000	13,327,000	18.7
Contract work	9,000	11,000	18.0
Cost of materials	25,974,000	49,272,000	47.3
Value of products	45,822,000	75,278,000	39.1
Value added by manufacture‡	19,848,000	26,006,000	23.7

* Figures given for 1921 do not include establishments reporting products below $5,000 in value. Eight establishments of this class reported a total of four wage earners and products to the value of $24,000. The figures for 1919, however, include three establishments of this class, reporting no wage earners employed and products to the value of $7,000.

† Percentages omitted where the base is less than 100.

‡ Value of products less cost of materials.

The figures for 1921 are preliminary and subject to such change and correction as may be found necessary after a further examination of the original reports has been made.

Use of Steam in Coal-Gas Retorts

The tendency toward lower standards of quality of gas in public utilities has increased the interest of the gas industry in processes that promise to increase the yield of gas per pound of coal coked, even though attended by a decrease in quality. The introduction of steam during or at the close of the coking process has shown considerable advantage in certain types of gas-making installations, notably in vertical retorts. The Bureau of Mines has co-operated with the American Gas Association in studying the effects of using steam in horizontal retorts, which are commonly used. It was found that the method of admitting steam had much to do with the results obtained. Little, if any, water gas was generated by decomposition of steam in the retort charge, unless the contact between the steam and the charge was intimate. Steam as usually introduced in the small gas plant where the process has been tried has no advantage. With prevailing standards of gas quality, little advantage can be taken of the use of steam, even if properly applied, as the production of any appreciable volume of water gas considerably reduced the general quality of the total gas production.

Only very recently has the thermal standard come to be universally adopted in place of the antiquated illumination standard. Should standards be further reduced, this process might show more marked economies.

Shaping Management To Meet Developing Industrial Conditions*

By H. S. Person
Managing Director, Taylor Society

An Analysis of Present Industrial Conditions—The Existence of a Buyers' Market for the Next Decade — How Management Must Change to Meet This Condition—What the Future Holds

In the conduct of any enterprise there is a major function, the responsibility for which resides somewhere in the organization, of determining future policy. In many enterprises this function may be regarded lightly, or even disregarded, on the principle that sufficient unto the day are the problems thereof; but in the larger enterprises, and in all well-managed enterprises of any size, it is not neglected. This is one reason for their good management.

The problem of future policy has many phases, of which the following come at once to mind: the commodities or services to be produced and sold; the quantities of these it is safe to attempt to produce and sell; the financial and technical equipment necessary; the technical methods of producing and distributing which shall be employed; the conditions of human co-operation which must be established in the enterprise. These, and many other major phases of policy not here enumerated, break down into numerous subsidiary but also individually important elements. The difficulty of solving the policy problem is not reflected in the simplicity with which these elements may be enumerated, for they are not clearly separable, but are complicated and cross-sect one another. Furthermore, solution of the policy problem requires measurements and estimates of elusive and changing governing conditions—the variable demands of markets for particular commodities and services; the variable strength of actual potential competition to meet these demands; the availability of financial and technical resources and changes in these; the availability of workers and the changing conditions of their co-operation; restrictions or regulations which may be imposed by governments, and so on. And thoroughgoing measurements and estimates of such things as these lead farther into the consideration of factors still more elusive; changes in the habits, tastes and mental attitudes of peoples; the probabilities of new discoveries and inventions; changes in the social machinery for the conduct of industrial operations; that complex of conditions generally designated by the inclusive term "industrial conditions."

What the American Executive Is

It is highly probable that an increasing number of enterprises will come to recognize that policy determination is a function which requires serious and continuous attention. It will involve the ascertainment of and analysis of facts concerning which executives have in the past had little interest, and it will involve, above all, much and careful thinking. It is questionable whether the American executive can be characterized as a thinking executive so much as one intuitional in reaction to immediate facts; he himself has been proud rather to consider himself the doer and go-getter par excellence—he who acts and gets while others think. If he is what he believes himself to be, he is the natural product of his economic environment; but one question to be raised tonight is whether there is not evident a sufficient change in the environment to make any such pride now unreasonable.

The particular phase of the policy problem which is to be considered tonight is presented in the question, "How must executives shape their managements to meet developing industrial conditions?" This question is fundamental, for a particular kind of management is an expression of decisions on many other matters of policy. The question is not to be understood as asking, "What new principles of management must be discovered and formulated to meet developing industrial conditions?" There are principles enough at our command—many more than have been generally recognized and utilized—to meet any conceivable conditions. We might change to a socialistic or communistic society and still be adequately served by the technical principles and methods already at industry's command. But under even moderately diverse industrial conditions we must utilize these principles and methods in different combinations, must weigh them differently, in accordance with the requirements of particular circumstances.

How Industrial Conditions Are Developing

Let us give our attention first to developing industrial conditions. A first glance is reassuring, for the revival due to follow the acute depression of 1921 is obviously already under way. This is indicated in all the reports of fundamental lines of activity. Bank clearings, car loadings, the production of basic commodities, and merchandise distributions have increased; stocks and bonds are more active; the spread between commodity prices has been reduced and in general a possible further long-run decline in commodity prices has been checked by price advances; there is an increase in employment and even in places a shortage of unskilled and skilled labor. Executives are reporting that they are "getting the red ink off their books"; and frequently there appear in the press optimistic utterances of captains of industry. We even already hear talk of a 1923 boom on the part of ultra-optimistic business men.

But a second, less superficial, consideration of conditions causes us to hesitate to join those who believe "it is all over except the shouting." May not this evidence of revival be only the evidence of rebound from the extreme depression, and may not the present rate of acceleration be only temporary, to be replaced by a rate more moderate? May not the projection of a curve into the future on the assumption of a continuance of the present rate of revival be a dangerous basis on which to establish managerial policy for the future? The more thoughtful and cautious fear so. When there is eliminated the activity to supply seasonal and terminable demand, and particularly the intensive activity to supply the abnormal demand for fundamental necessities to which the exigencies of war denied satisfac-

*Paper presented at a meeting of the Taylor Society, New York, Nov. 23, 1922.

tion—for instance, construction and all the lines of industry attendant on construction—when there is observed the fact that consumers' demand for a wide range of commodities and services is continuing to be hesitant and cautious, there is not left a sufficient amount of evidence to warrant a projection of the curve of industrial activity into the future at its present gratifying slope.

Consuming Public Has Cut Purchases

This point of view is expressed by a careful special correspondent of a dependable New York financial paper in a report from New England: "The only inference to be drawn [from facts enumerated] is that the bulk of the consuming public has been cutting off one thing after another in order to make its income go as far as possible in the matter of the commodities which it considers essential. Briefly, there are indications of a shrinkage in the American standard of living, which perhaps does not augur well for a long continuance of the present upward trend of industry, so called." How many in this audience have not reduced their standard of living from what it was during the period of 1914-1921, and how many, because of personal circumstances, do not expect to continue to keep it reduced for some time to come? The demand permitted by the aggregate of personal circumstances is what makes the market.

A third and more penetrating analysis, this time of more fundamental conditions, is even disconcerting to those who believe it is all over except the shouting. During the past decade, as a result of the study of earlier cyclic movements, we have learned that certain economic phenomena, such as the quantity of money and credit, have a definite relation to industrial activity. The store of money and credit influences prices and the price movement influences industrial activity. We should recall that the long period of accelerating industrial activity culminating in the frenzy of 1920-21 was coincident with a long upward swing in prices; that in general industrial activity increases in intensity with an upward price movement, is stagnant when there is a downward price movement, and is hesitant and uncertain in the early years of a new stable price level. Of course, the ideal condition is a fairly stable general price level, but when a condition of stable price level suddenly confronts an industrial generation which has become accustomed to a consistent upward price movement over a long period, the new condition of stability, because different from the accustomed, is upsetting to the individual, either as demander or producer, and it takes a considerable period, measured not in months but in years, for him to learn just what he can safely do both in purchasing and in producing.

Views of Harvard Committee

During recent years some sound work has been done in the analysis of fundamental industrial conditions and tendencies, which has given a basis for policy determination more substantial than anything we had previously had. It may be observed that during the past 3 years of experience wholly new to us the forecasts of these investigations have "called the turn" more accurately than the prophecies—or guesses—of business men. These investigators have succeeded in making some accurate measurements of basic elements which determine price conditions for a number of years ahead, and the safest judgment to accept is that, in the words of the Harvard Committee on Economic Research, "the present price level is substantially that around which the fluctuations of the business cycle must play" for the next 10 years. I make my own private reservations to that broad statement, for I believe the committee has failed to take into consideration the capacity of American managerial genius to increase vastly, when put to it under intensely competitive conditions, the quantity of goods for exchange which may be produced from a given combination of plant, equipment, materials and labor; but perhaps the committee is wise in not taking that into consideration, for it depends upon the wills of owners and managers, who are a conservative group when it comes to the adoption of new production methods.

Assuming that forecast to be correct, what is likely to be the effect of a new, high price level "around which the fluctuations of the business cycle must play"? Simply that you and I are, for a number of years, going to continue to be conservative as purchasers, and also conservative as producers. As producers we are going to wait for demand, and as demanders we are going to wait until we have adjusted our purchases to the new relation between our incomes and the cost of living. It is true that wages are settling at a new high level, but there still remains a large number of consumers whose incomes are not readjusted so easily and quickly, whose incomes as at present and will for some time continue to be adjusted rather to the old price level, and it does not take a very large bloc of maladjusted consumers to keep the market unsteady and uncertain.

The Market for the Next Decade

The conclusion I would have you draw is that for, say, a decade, consumers' demand is likely to remain so hesitant and uncertain as to be out of proportion to our capacity to produce. It does not seem necessary for me to give this particular audience any proof that the war has disclosed that our capacity to produce far exceeds anything we had believed it to be. I have talked recently with observing men who have covered the country from Maine to California, and they have reported that the most impressive single fact of their observations is the tremendous capacity of American industry to produce. You will recall President Friday's address at a meeting of this society two years ago; he stated that one outstanding fact is the increase in our productive capacity during recent years, and that if the war has taught us anything, it is that we allow a large part of that capacity to "run to waste through sheer idleness." Now I put this question to you as practical managers: If our productive capacity is so great, and if it can be made much greater simply by eliminating sheer idleness, and if consumers' demand is fairly certain to be hesitant for the coming decade, have you or have you not a really critical management problem?

However, before considering the kind of management that problem is going to force upon you, I want to make one more, a fourth, analysis of present industrial tendencies, painting the picture upon a large canvas. Let us give the picture a striking American title: The Overland Trail—from a dominant sellers' market to a dominant buyers' market. We all appreciate that we are now in at least a temporary buyers' market; I am suggesting that we are on the trail to a dominant buyers' market, and that we are possibly already on the great divide. If we are, we shall learn to manage our enterprises differently.

A summary review of the industrial history of the United States should make it patent that we have been brought up in a sellers' market. We have been pioneers—explorers, appropriators and exploiters of a vast continent of extraordinary resources. It has been a California of '49, or a Klondike, on the scale of a continent and a century. The exploitation of resources which have always had an immediate world market and cash value, the appropriation of stores of capital and treating it as income, has given our population a geometrically increasing purchasing power. Consumers' demand has kept ahead of and pulled along producers' capacity to satisfy the demand.

A Buyers' Market

But there comes a time in the history of an appropriating and exploiting people when they cease to be frontiersmen and appropriators; when the stores of nature's wealth are uncovered and appropriated, when future income through exploitation is capitalized at current values, when income becomes real income derived from productive effort and ceases to be in large part the appropriation of capital resources; when there emerges on the one hand a class of *rentiers* and on the other hand a larger class of laborers, clerks, sub-executives, major executives, merchandisers and others whose income is, on the whole, limited by the productivity of their efforts and whose consumers' demand power tends to become correspondingly fixed. In other words, industrial society tends to become more stratified and stable. There is then the danger of a period of maladjustment when technical equipment and productive capacity have overreached immediate demand, and when, if other markets are not sought, a buyers' market succeeds a sellers' market as the dominant factor in the industrial situation.

There were signs before the war that the industrial development of the United States was approaching that stage of evolution. Natural resources had become pretty well appropriated and capitalized—not only such resources as mines, forests and natural transportation routes, but also agricultural lands, for there was before the war an increasing proportion of tenant farmers, paying rent in cash or shares. Serious students were concerned over this tendency. Technical productive equipment was at the same time greatly increased, and there was no sign of a plan or even a clear intent to develop foreign markets. President McKinley's turn, just before his death, toward a reduction of the tariff obstacle to the development of foreign markets made no impression on the dominant political party, and there continued a period of tariff policy which has culminated in the Fordney-McCumber bill. It seemed to thoughtful observers that the quarter century before the war was a period of conscious or unconscious eat, drink and be merry, for today we are getting ours and tomorrow will take care of itself.

War Hastens Market Evolution

Then came the war, which was a tremendous shock to the industrial system. On the one hand it caused a still greater development of productive capacity, financed out of future earnings through the mechanism of bonus and taxation, and caused a coincident decline in consumers' demands (the frenzy of 1920 was but an unsubstantial flare-up), a decline which is likely to continue for some time because of the continuing heavy taxes and the maladjustments caused by the war. In short, the shock seems to have hastened evolutionary tendencies which would have developed more gradually and with only relatively minor depressions, and to have thrown us suddenly upon a buyers' market which will last for some time and may be the beginning of a dominant buyers' market.

What a Buyers' Market Means

A buyers' market means, for industries that are not competitive, a more radical and restrictive control or regulation, for when buyers look long at the dollar before parting with it, they look longer at the conditions which create the necessity for parting with all of it; and it means, for competitive industries, a strife for the consumers' dollar which makes so-called competition on a sellers' market seem but a children's game. In view of all these considerations, I think you will agree with me that there was never a time when management should have more concern over future policy—and over the quality of its future management.

Management on a buyers' market is quite a different thing from management on a sellers' market. On a sellers' market selling is but order-taking; on a buyers' market it must be real merchandising. On a sellers' market production is but the hasty and wasteful process of giving material things a form or other quality which will satisfy insatiable and not overcritical demand; on a buyers' market it must be more precise and economical. On a sellers' market financing is largely borrowing on the assumption of unexploited natural resources or an unexploited upward market; on a buyers' market it is a borrowing on demonstrable future earned profits. On a sellers' market the conduct of a business is easy and management is simple—in fact, there does not have to be any real management. But now that you appear to be face to face with a buyers' market and the necessity of developing real management, if you are to be successful in a most intense competition, if your competitor, instead of yourself, is to be the one to disappear in some readjustment of productive capacity to consumer demand, it is expedient for you to inquire into the nature of that real management.

The Problem Involved

The essential practical elements of the problem confronting that management may be summed up as follows: On the side of supply there is a tremendous production capacity involving heavy investments of capital in more or less specialized equipment, to preserve the value of which will require a continuation of the lines of activity for which it was designed. On the side of demand there is a conservative and hesitant market—in fact a buyers' market—which will continue for a considerable period. This will mean intense competition on the part of management to find the individual consumers and to sell them. In that competition selling price and cost of production will be critical factors. The hesitant market will tend to force selling price down, while higher prices of certain elements entering into cost will tend to keep that figure up.

The fact cannot be disregarded that, as was the experience after both of our earlier great wars, wages have settled at a new high level, and that the strength of organized labor and new immigration policy seem sufficient to hold them there during such a period as will determine the success or failure of competing enterprises. It should be observed also that many of the basic materials of industry are more or less closely

controlled, and that material costs are likely to remain high. Therefore management will be faced by high prime costs in the face of great pressure to reduce the selling price of fabricated products. The way out for the successful competitor appears to be this: to develop an inclusive system of management which will more than compensate for high prime costs by cost savings elsewhere, thereby effecting lower factory costs and making possible lower selling prices or making possible a higher quality of product at the original cost and selling price.

In the first place that management will give more attention to such problems as we are considering tonight—long-run tendencies in the industrial environment. These matters will no longer be regarded as merely "theoretical"; they will be regarded as very practical. Certain major executives will give more thought to policy and general plans, and not permit themselves to become too much absorbed in operating details and worn out by late afternoon worries. They will not confine their reading to the news headlines and market quotations of newspapers, but will read under the headlines, search for the facts and do some thinking of their own. They will find time for—and consider as important as some of the things for which they now find time—the reading of magazines of fact and opinion relating to administration, management, economics, politics and industrial relations. They will have in their organizations a unit to study and interpret industrial statistics. In illustration, a major executive of a certain medium-sized plant inquired of the Taylor Society the other day where he could find a young man, a college graduate trained in economics and statistics, to study for him the periodic reports of statistical service, and interpret them for the management in terms of the particular business. That enterprise is getting the jump on competitors.

Managers Must Study Markets

That management, in the second place, will provide for a more accurate judgment of the market with respect to the demand for the commodities it has to offer, competitors' ability to supply the demand, and what share of the market it can have reasonable expectation of securing. It is with the consumer that the impulse for industrial activity begins—"the consumer is king"; but on a sellers' market consumers are so numerous and insistent that we forget the source of the impulse and come to believe that it starts with the producer. Under the competitive conditions of a buyers' market, managers will see that in true perspective. Managers will learn that they cannot afford to misjudge demand, either with respect to what it wants, how much of that it wants, or what share of it competitors will permit a particular enterprise to provide. Excessive inventories are fatal on a buyers' market. An enterprise must avoid that by some unit of the organization, whether it be an individual or a group, which will make continuous and precise analyses of the market and provide the data for master plans and schedules. Call it what you will—market research, merchandise research, sales engineering.

In the third place, that management will set up in writing, on the basis of the data secured by market research, definite master plans, budgets and schedules of operations for a considerable period ahead, these being supported by definite and interdependent detail plans and schedules for the major operating departments —selling, production and financing, respectively. These master plans and schedules, and these supporting departmental plans and schedules, will be standards of performance, goals to strive for, lines to which to hew. To do without such plans and schedules means guessing, taking chances, departments out of alignment, unbalanced inventories, higher costs—losses for which the consumer willingly pays the price on a sellers' market, but which, on a buyers' market, become a loss to the producer which he cannot afford when competition is intense.

That management, in the third place, will have to conduct its selling operations with more skill than it has ever displayed before. On a sellers' market the consumer seeks the producer; on a buyers' market the producer must search out the consumer and sell him, in the midst of a keen competition both of other producers of the same commodity and other uses of the consumer's dollar. Just as there must be no misjudgment of the market, lest there be unsold inventories; no failure to make precise plans and schedules, lest there be unsold inventories; so also there must be no failure to search out and sell to the estimated number of consumers, or there will be unsold inventories.

Changes Caused by Buyers' Market

Are we able to imagine the detail changes which are likely to follow the development of the new merchandising? Is it not probable that there will be less of that advertising whose object is to create new wants in satisfaction of which consumers would spend surplus dollars, and more of that advertising whose object is to convince concerning the quality of staple merchandise offered in competition for the limited supply of dollars? Will not the work of salesmen be something besides either mere order-taking or mere psychological suasion; is not the salesman more likely to spend more time searching out prospects; calling on prospects as well as established customers; skillfully displaying the merits of goods; rendering intelligent—even scientific—service; planning and scheduling his work? Will not the supervision of sales executives and their assistants be more comprehensive and more skillful—again, more scientific—than anything we have seen; salesmen better selected, better trained, their work better planned and scheduled and given more intelligent and effective support by the directing staff? Will not the channels of distribution be more carefully studied and more discriminately selected?

I have called attention first to market analysis, master plans and budgets, and selling, as conspicuous features of the new management, not because they are superior in importance to other phases of management, but because they logically come first—the point of origin from which to lay out the operations of an enterprise being the consumer—and because in the sellers' market of the past these phases have been most neglected. It is not to be assumed, however, that I attach less importance to better production methods as a feature of the new management.

Good Production Methods Necessary

There are some who assert that the production problem is solved and that we should now give most attention to other phases of management. I believe they are too hasty in their judgments, especially if we are thinking in terms of a severe competition on a buyers' market. The production problem is far from

solved. It is true that we know more about good production management than about good sales management, and that we have a body of production management principles and practices at our command which, if utilized, would eliminate waste, reduce factory costs and permit price reductions to an astonishing extent; but it is equally true that they are not generally utilized, and the educational task of bringing about their utilization in a plant is as difficult and time-consuming a task as developing market analysis and improved selling methods. Perhaps more so, for the development of market analysis, master planning and selling is the problem of a small group of specialists, while the development of superior production methods is a problem involving the precise co-operation of many individuals of varying capacity for co-operation.

Furthermore, the more severe the competition the more important become good production methods. For in the final analysis, no matter how accurately we gage the market, how precisely we prepare schedules of operations, how skillfully we sell, the greatest weapon in competition is the combination of a dependable product, a dependable service and a quotation lower than competitors', and it is superior production methods which contribute most to making this weapon possible. If you can safely and consistently quote a lower price for an identical commodity and have a reasonably good selling organization, your competitors will hold you in dread.

Waste Must Be Eliminated

In the fourth place, therefore, the superior management of the next decade will develop the production department to a high degree of precision, in accordance with principles and methods already formulated and available. As some strong merchandisers secure their profits by taking discounts, so strong manufacturers can take their profits by eliminating waste—the waste of useless or unused plant; the waste of useless, unused or inefficiently used equipment and tools; the waste of unsuitable, inadequate or lost materials; the waste of inefficient methods; the waste of improperly chosen, improperly assigned, improperly instructed and inadequately inspired workers. Investigations and experiments will be conducted which will disclose the best equipment, tools, methods and materials for the fabrication of the product, and on the basis of the discovered best details will be established standards of product, equipment, materials and processing. Provision will be made for the maintenance of these standards, and these once established and maintained, a control of operations through planning, scheduling and checking of progress will be possible, which, as has been demonstrated in too few but an adequate number of instances, forges the competitive weapon of lower costs and lower quotations.

Finally, that management will win the co-operation of all the personnel of the enterprise, not as a matter of humanitarianism but as a matter of technical necessity. Without such co-operation all other provisions for excellence of management are impaired. The good will of the personnel is in many instances the determining factor in successful competition. The combinations of elements by which this good will is won may be different in different enterprises, but all will be identical in at least two respects: a group of elements which secure the personnel's cordial consent to the standards of all kinds which are established, and a sharing of the product of combined effort through wages which satisfy the personnel as reasonable and just.

The entire personnel of an institution, from major executive to the latest recruit, should be a co-operating group of individualities—co-operating, in the sense that each must play a part in a system of operations; individualities in the sense that each should be an original source of inspiration and new ideas and a creator of new methods which fit and promote the work of the system. Too many institutions simply inbreed. Individuals lose their individuality and the organization loses its vitality. The greatest asset of an organization is not plant and equipment, cash in the bank, or even an organization of persons; but a spirit of co-operation, an atmosphere of live interest in the best management principles and practice, an *esprit de corps* of search for wiser policies and better methods and individualities which have not lost the power of creation within co-operation.

It is not out of place to call attention to a special aspect of the new management—the utilization of a new type of executive. The long sellers' market of the United States has developed highly one particular type of executive—the forceful, acquisitive, go-getter type which drives straight to results regardless of methods and cost. But while the forceful, go-getter type of executive will always be essential, managers have come to realize that an organization must be balanced by the inclusion of the thinking, investigating, planning type of executive who surveys conditions and tendencies, formulates precise plans, establishes schedules and budgets, keeps departments co-ordinated, maintains precise control of operations, has regard for efficiency and economy of methods, and all the time appraises progress and results in terms of plans. Even the go-getter executive must become a thinking, planning executive after the enterprise is well established as a going concern. The thinking and planning type of executive will play a decidely important part in the future.

What the Future Holds

In conclusion, it should be understood that I am not pessimistic concerning what I believe is likely to be the developing industrial conditions. At the worst, consider what has been said as a word of warning. In the long run our very capacity for production will solve the problem, as it has in the past solved it under comparable circumstances; but the restorative power of that capacity for production must be realized chiefly through a regulation by better individual managements. We shall have short-time cyclic variations but fundamental increasing prosperity for industry in general during the decade of correction of maladjustments to new conditions. Note, however, the significance of the words "for industry in general." In the probable readjustment through competition on a buyers' market, some enterprises are certain to disappear, and they will be those particular enterprises which are satisfied with the management which is "just as good as the average," for that mental attitude almost invariably means managements which are poorer than the average. For a quarter century before the war even poorly managed enterprises were helped in their ascent to the heights of prosperity by the escalator of a sellers' market; now that escalator is out of commission, and the ascent to new prosperity must be achieved in the good old fashioned way—by good management muscles, good management lungs and good management brains.

Two Forms of Nitrogen in Steel

By Louis Jordan and F. E. Swindells
Chemist and Assistant Chemist, Bureau of Standards

When heat-treating two heats of silicomanganese spring steel it was found that certain hardening treatments very noticeably increased the combined nitrogen in one steel made in an electric furnace,[1] while an open-hearth steel of almost identical composition showed practically no increase in combined nitrogen.

The manufacturer's analyses of these steels for the usual constituents gave the following results:

	C	Mn	P	S	Si
Steel A (electric)	0.53	0.77	0.022	0.014	2.09
Steel B (open-hearth)	0.54	0.77	0.017	0.022	2.03

Analyses of the rolled stock as received by the bureau showed in the electric steel twice as much combined nitrogen as in the open-hearth steel (Table I).

TABLE I—COMBINED NITROGEN IN SPRING STEELS AS ROLLED

Electric Steel		Open-Hearth Steel	
Sample No.	Per Cent Nitrogen	Sample No.	Per Cent Nitrogen
A16	0.0041	B29	0.0019
	0.0051		0.0022
A2	0.0038	B1	0.0025
	0.0047		0.0031
	0.0051		
Average	0.0046	Average	0.0024

Further analyses were made on samples of steels A and B which had been given (1) a regular hardening treatment, as practiced by spring manufacturers, (2) a normalizing quench followed by the regular hardening treatment, (3) a sample of steel A which had been subjected to the normalizing quench only. In the "regular" treatment, (1) above, a hardening temperature of 900 deg. C. (1,650 deg. F.) was used. The normalizing quench (2) was from a higher temperature—namely, 980 deg. C. (1,800 deg. F.).

Combined nitrogen in the open-hearth steel was changed but little if at all by the treatments given. However, either a normalizing quench or a normalizing quench followed by the regular treatment doubled the amount of combined nitrogen in the electric steel (Table II).

TABLE II—INFLUENCE OF HEAT-TREATMENT ON COMBINED NITROGEN IN SPRING STEELS

Treatment	Electric Steel			Open-Hearth Steel		
	Sample No.	Per Cent Nitrogen	Average	Sample No.	Per Cent Nitrogen	Average
As received			0.0046			0.0024
Regular hardening treatment	A4	0.0065		B2	0.0037	
		0.0068	0.0066		0.0023	
					0.0024	0.0028
	A5	0.0061				
		0.0064	0.0063			
Normalizing quench	A20	0.0098				
		0.0086	0.0092			
Normalizing followed by regular treatment	A31	0.0109		B19	0.0025	
		0.0095	0.0102		0.0035	0.0030

It is difficult to believe that the heat-treatment itself as carried out could increase the total amount of nitrogen in the electric steel and make no change in the open-hearth steel treated simultaneously. It seems probable, in view of the limitations of the solution method for nitrogen explained in a previous article,[2] that there is no increase in the total nitrogen in the steel, but that some nitrogen that was originally present in some form not determined by this method was converted into a form that permitted its determination.

Of interest in this connection is a patent granted to Krupp Akt.-Ges.[3] which has claims based on the introduction of nitrogen into steel at temperatures below 580 deg. C. in the form of solid solution, as distinct from nitride of iron which is formed on heating above that temperature.

Electrolytic Iron Treated With Calcium

A series of ingots of electrolytic iron was next examined to determine if similar changes in combined nitrogen could be detected in iron free from the usual metallurgical impurities or alloying elements. These ingots had been prepared for another purpose and to all but one (ingot 385) small amounts of metallic calcium had been added just before casting in a chilled mold. Melting was done in a high-frequency induction furnace in crucibles made of 85 parts of magnesia and 15 of zircon. Combined nitrogen was determined in these ingots as cast. They were then given a heat-treatment similar to the treatment which gave the greatest increase in combined nitrogen in the electric furnace spring steel—namely, a normalizing quench from 1,040 deg. C. (1,900 deg. F.) followed by a second quench from 910 deg. C. (1,670 deg. F.). Table III shows that there was nearly always a marked increase in the combined nitrogen. Four of these treated ingots were annealed at 950 deg. C. (1,740 deg. F.) for one-half hour and then cooled slowly over a period of about 4 hours. No very definite change in the combined nitrogen was caused by this treatment—the slight differences observed were not uniform in direction.

TABLE III—COMBINED NITROGEN IN ELECTROLYTIC IRON INGOTS TREATED WITH CALCIUM*

Ingot No.	Per Cent Nitrogen As Cast	Average	Per Cent Nitrogen After Heat-Treatment	Average	Increase Due to Quenching	Per Cent Nitrogen After Annealng	Average
380	0.0087		0.0111			0.0126	
	0.0082		0.0101	0.0106	0.0018	0.0112	0.0119
	0.0096	0.0088					
381	0.0015		0.0029			0.0029	
	0.0030	0.0022	0.0037			0.0032	0.0030
			0.0051		0.0022		
			0.0059	0.0044			
382	0.0030		0.0050				
			0.0054	0.0052	0.0022		
383	0.0015		0.0040				
			0.0042	0.0041	0.0026		
384	0.0028		0.0042			0.0042	
			0.0037		0.0011	0.0030	0.0036
			0.0037	0.0039			
385	0.0016		0.0036			0.0024	
			0.0038	0.0037	0.0021	0.0021	0.0022

* The calcium added was equivalent to 0.2 per cent in 380 and 381; 0.1 in 382; 0.03 in 383; 0.01 in 384. No addition was made to 385. The residual calcium in the ingots ranged from 0.04 to 0.003 per cent.

Autoclave Steel

There was next examined a specimen of steel from an autoclave used for containing the catalyst and nitrogen-hydrogen gas mixture in the Haber process for nitrogen fixation. The gas mixture in this autoclave was treated at a pressure of 1,500 lb. per sq.in. and at a temperature of 500 deg. C.

	C	Mn	P	S	Si
Outside layer	0.42	0.65	0.031	0.033	0.29
Inside layer	0.14	0.65	0.032	0.036	0.29

Published by permission of the Director of the Bureau of Standards, U. S. Department of Commerce.

[2] "Determination of Combined Nitrogen in Iron and Steel," by Louis Jordan and F. E. Swindells, *Chem. & Met.*, vol. 27, No. 23, p. 1125, Dec. 6, 1922).

[3] F. Krupp Akt.-Ges., Brit. Pat. 174,580; *Chem. Abs.*, vol. 16, p. 1738 (1922).

Analyses of the inside and outside layers of the plate for the usual elements showed considerable decarburization of the inside layer.

Nitrogen determinations showed that the inside contained about 50 per cent more combined nitrogen than the outside. One sample of this plate was given the regular hardening treatment previously referred to in the case of the spring steels and another sample the normalizing quench followed by the regular treatment. There was a very marked increase in the combined nitrogen in the outside layer with both heat-treatments. In the inside layer there was no change in the combined nitrogen. (See Table IV.)

TABLE IV—COMBINED NITROGEN IN AUTOCLAVE STEEL

	As Received		Regular Treatment	Normalizing Followed By Regular Treatment	
	Per Cent Nitrogen	Average	Per Cent Nitrogen	Per Cent Nitrogen	Average
nside.....	0.0145		0.0145	0.0146	
	0.0140	0.0142		0.0156	0.0151
Outside.....	0.0091		0.0162	0.0149	
	0.0093	0.0092		0.0128	0.0138

The failure of the combined nitrogen of the inside layer to be altered by heat-treatment may possibly be explained by the fact that the conditions of service (namely, at 500 deg. C. in the presence of hydrogen and nitrogen under pressure) were such that all the nitrogen, both originally present and diffusing into the plate, was converted during the operation of the autoclave into the form determined by the solution method. The outside layer of the autoclave plate was possibly at a lower temperature than the inside layer, a temperature below that necessary to convert to the nitride form the nitrogen diffusing from the interior.[4] A still more probable explanation is that the presence of hydrogen was necessary to cause all the nitrogen to form nitrides and that the outer layer of the plate was beyond the zone of hydrogen penetration, a fact indicated by the decarburization being limited to a narrow inner layer.

Fused Electrolytic Iron

An attempt was then made to check the previous results obtained with the electrolytic iron. Three ingots of electrolytic iron were prepared in a high-frequency induction furnace and cast in a chilled mold. One was melted under quiet air in a crucible of 85 parts of magnesia and 15 parts of zircon. The two others were melted in pure magnesia crucibles, one being under quiet air and the other under a stream of pure nitrogen. These ingots were given the same heat-treatment as the first electrolytic iron series—viz., a normalizing quench followed by hardening. No change in the combined nitrogen could be detected (Table V).

TABLE V—COMBINED NITROGEN IN ELECTROLYTIC IRON

Ingot No.	Method of Preparation	Per Cent Nitrogen As Cast	Average	Per Cent Nitrogen After Heat-Treatment	Average
388	MgO-zircon crucible; under air	0.0033		0.0031	
		0.0030	0.0032	0.0030	0.0030
456	MgO crucible; under air.....	0.0033		0.0034	
		0.0056		0.0034	
		0.0056	0.0048	0.0030	0.0033
457	MgO crucible; under nitrogen....	0.0070		0.0071	
		0.0072	0.0071	0.0065	0.0068

It is improbable that the observed increase in combined nitrogen in the above metals is due to nitrogen introduced during heat-treatment, since the electric and open-hearth steels were treated simultaneously, as were also both layers of the autoclave plate. The increase was found in one member of each pair but not in the other. In other words, the total nitrogen in these metals was not increased.

It is likewise improbable that the increase in nitrogen determined by the Allen method is due to the formation of iron nitride following the decomposition of nitrides not determined by this method of analysis, since this increase in combined nitrogen also took place in the first series of electrolytic iron ingots, which contained as the only impurity mere traces of calcium, the nitride of which is readily decomposed by acids.

It is to be concluded that nitrogen may be present in iron and steel in more than one form—as combined or nitride nitrogen and as uncombined nitrogen. The changes in the amounts of combined nitrogen are probably the result of conversion of free or uncombined nitrogen to nitride nitrogen. The free or uncombined form of nitrogen is not present in all samples of iron and steel, or may vary widely in amount.

The authors wish to acknowledge their indebtedness to H. J. French for carrying out heat-treatments of the metals examined and to H. A. Bright for making the chemical analyses other than those for nitrogen.

[4]Compare the claims of the Krupp patent, note 3.

Spanish Trade in Chemicals

Before the war Spain imported from abroad a great part of the chemical products employed by her industries, especially coloring matters derived from coal.

From the point of view of tonnage landed in Spain, the first rank was taken by superphosphate of lime and basic bessemer slag; then the following products may be quoted as having given rise to a good current of business: Vegetable preparations for the dyeing industry, vegetable preparations for medicinal purposes, coloring matters, sulphur (raw and refined), alkalis, insecticides and sulphate of copper, feculas for industrial purposes, gums, dextrine, etc., for stiffening purposes, paraffine and nitrate of soda.

Germany despatched approximately 25 to 30 per cent of the importations of this class of goods; Great Britain 20 per cent; the British possessions in Asia 12 to 15 per cent; the Dutch colonies 6 to 7 per cent (the two last-named regions sent principally oilseeds), while France's share of this trade amounted to between 10 and 12 per cent.

During the war the Spanish industry, finding itself mistress of the home market, equipped itself to supply a considerable number of products of which the importation had ceased; for example, arrivals of dyestuffs derived from coal fell from 1,351,058 kg. in 1914 to 406,342 kg. in 1917. This industry consequently insisted on a high customs tariff.

It seems that the commercial conventions inaugurated during the past 6 months will facilitate to a certain extent the importation of chemical products into Spain, but the final result cannot yet be foreseen.

It appears that in the case of some articles foreign industries must face a diminution of their sales in Spain, unless a great difference in the cost price can be attained. The manufacture of sulphuric acid and nitric acid has greatly developed in Spain.

The Minister for War intends to buy a large piece of ground (700 hectares) in the neighborhood of Madrid for the purpose of erecting chemical works with annexes in order to be able to manufacture products required for national defence now purchased abroad.

Gasification of Ohio Coals—I

The First of Two Articles Presenting the Results of a Preliminary Survey Made to Determine Suitability and Economic Value of Various Ohio Coals for Gas-Making Purposes

By D. J. Demorest
Professor of Metallurgy, Ohio State University

THE natural gas production of Ohio has dropped so far below the demands of that state that out of the total consumption of 145,000,000,000 cu.ft. in 1920 Ohio produced only 60,000,000,000 cu.ft., the difference being made up by gas piped in from West Virginia. The new wells drilled in Ohio all come in with lower pressure year after year. It is obvious that the natural gas supply will grow less with each year and will soon be entirely inadequate for the state's needs even with gas from West Virginia.

These facts were so evident several years ago that it became a matter of immediate importance to institute a survey to determine what resources the state possesses for the making of manufactured gas to supplement and ultimately completely to supplant the natural gas. The writer presented the case to the Engineering Experiment Station of the Ohio State University and the Legislature was asked to appropriate a sum sufficient to erect an experimental plant whereby the gas- and byproduct-making values of the coals of Ohio might be determined. The Legislature made such a grant to the Engineering Experiment Station, out of which $10,000 was allocated for this coal-testing work to cover the cost of erecting the plant. The gas and coal interests of Ohio were then asked to appropriate funds for operating the plant for one year. The Southern Ohio Coal Operators' Association through W. D. McKinney, its secretary, made a grant of $200 per month for one year and the Gas and Oil Men's Association through W. H. Thompson, its secretary, granted $100 a month for one year.

The Purpose of the Survey

It must be distinctly borne in mind that the researches reported in these articles constitute only a preliminary survey. It is hoped and expected that this preliminary survey will enable us to classify our coals so that we shall know which ones to select as the most economical for gas making, and then concentrate more detailed work upon those coals in order to discover exactly the best conditions for their gasification and to establish with a fair degree of accuracy their economic values to the gas industry.

Each coal yields its best value upon gasification under its own peculiar conditions. For instance, some coals must be gasified at comparatively high, others at comparatively low temperatures. The amounts of gas made, the total number of heat units in the gas, the number of heat units per cubic foot, the amount and nature of light oils recoverable, the amount and nature of the tar produced, the amount of ammonia recoverable, the impurities in the gas (such as hydrogen sulphide and naphthalene) and the quality of the coke all vary with the rate of gasification and the temperature. The amounts and qualities of these products which can be recovered also vary with the fineness to which the coal is crushed before charging in the retort and with the amount of moisture in the coal. It is also true that many coals which are not economically gasified alone may be very valuable for gasification purposes when mixed with a characteristic amount of some other coal.

In this preliminary survey it was possible only to carry out the carbonization experiments at the average temperature of 1,000 deg. C., which will probably give the best results for some coals but is too low a temperature for some other coals and possibly too high for still others. Furthermore, it was not possible in this preliminary survey to discover the optimum fineness for crushing nor to attempt to find the results obtainable by mixing coals or regulating the moisture content. In the further work which is to be done on certain selected coals, the economies resulting from steaming the coals and resulting from the use of sized coal will be ascertained.

In this work it was realized that the most highly refined methods for determining the benzol yield and the distribution of sulphur in the gas were not justified,

FIG. 1—FRONT VIEW OF RETORT STRUCTURE

because of the fact that in the preliminary work the time and money were not available for ascertaining the retort conditions which would give the best yields for each coal. Hence only comparative results were sought.

It is believed, however, that the results obtained from this preliminary survey are reasonably accurate and afford a basis for the selection of those of our coals upon which further detailed work should be done. Furthermore, they give a rough evaluation of all the coals for gas making.

The retort selected for gasifying the coal is an intermittent vertical type of exactly the same shape and dimensions as those in commercial use. In fact, the retort erected was an extra one of the 250 retorts

FIG. 2—SIDE VIEW OF RETORT STRUCTURE

erected at Rochester, N. Y., for the city gas supply. The United Gas Improvement Contracting Co., which erected the Rochester plant, also erected this experimental retort, generously doing it at cost.

The equipment required for recovering tar and ammonia from the gas made and the arrangement of machinery were designed in the department of metallurgy and erected by university mechanics.

The equipment for crushing the coal, washing the coal and testing and analyzing the products made are all a part of that possessed by the department of metallurgy.

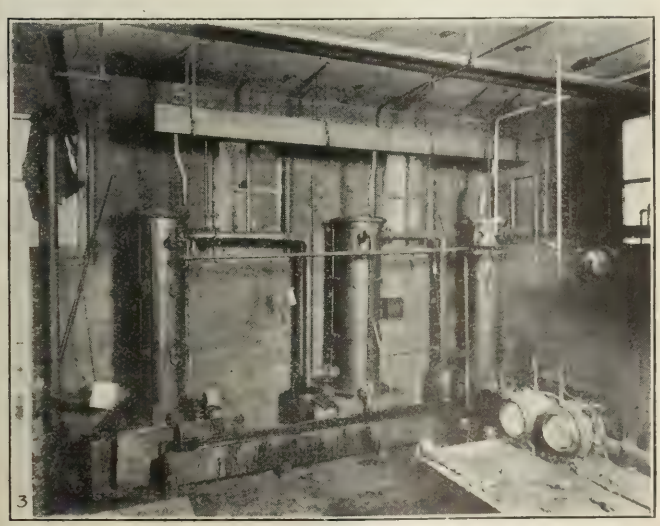
Figs. 1 and 2 are photographs of the retort structure and Figs. 3 and 4 are views of the byproduct recovery system. Fig. 5 is a diagrammatic sketch of the plant.

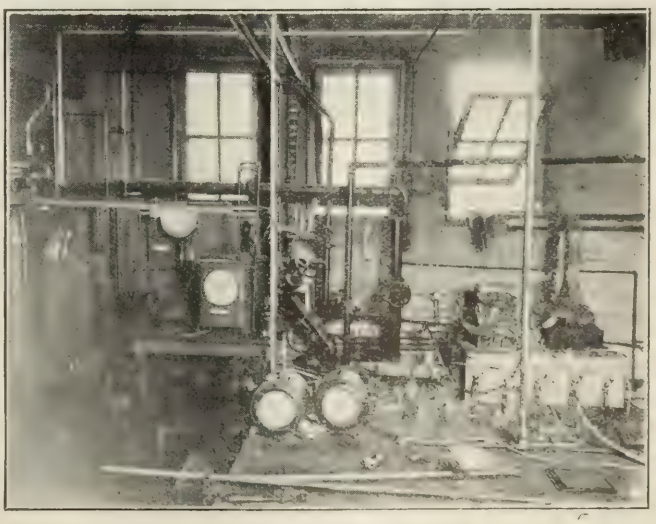
The retort carries a standard charge of 1 ton (2,000 lb.) of coal. The charge is all run in a fraction of a minute, and remains in the retort until the carbonization of the entire ton is complete, requiring 10 to 17 hours. In other words, the retort is of the intermittent type of vertical retort—not of the continuous type. The retort is heated for convenience sake with natural gas, burning at three different levels and giving an exceedingly uniform temperature around the entire setting. The temperature of the setting was recorded by a Brown recording pyrometer with the thermocouple halfway between the top and bottom of the retort. The thermometer was checked by a standard thermocouple and an optical pyrometer and was found to be correct.

The gas passes from the top of the retort *A* (see Fig. 5) through the bridge pipe *B* into the foul main *C*, thence down pipe *D* into the bottom of and up through scrubbing tower *E*, thence into the bottom of and up through scrubbing tower *F* and similarly through tower *G*. From tower *G* the gas is drawn through the exhauster *H* and to the furnace *I*. By means of the pump *J* a dilute sulphuric acid solution is continuously circulated through towers *E* and *F*. Cold hydrant water passes down through tower *G* and through the cooling coils *Z*, thence to waste. The cooling coils keep the circulating acid from becoming too warm. These scrubbing towers are filled with wooden grids staggered so that the gas and circulating liquids must come into intimate contact. The circulating acid solution removes all the ammonia from the gas and practically all of the tar not previously condensed. At *K* some gas is drawn off continuously for the determination of sulphur; at *L* the gas is sampled continuously for its "light oil" contents; at *M* a sample is continuously drawn for the determination of the B.t.u. value of the gas by means of a Smith continuous recording gas calorimeter, and at *N*, the gas is metered by a Bailey orifice gas meter, which continuously records the rate of gas making and integrates the total volume made.

The bottom of the retort setting is a heavy iron casting with an opening the size of the interior of the retort. This opening is closed by a cast iron door, *DD*, which is hollow and which is aligned with a channel in the iron bottom plate so that the tar which drips down against the door may drain out into tank *S*. The door is lifted into place before charging the coal and lowered for the discharge of the coke by means of a triplex chain-fall. The coke drops into a portable steel tank and is then dragged from under the retort and quenched with water drawn from an elevated reservoir.

Through the offices of the purchasing agent of the Ohio State University and the secretary of the Southern Ohio Coal Operators' Association carload lots of coal representing the important fields and seams of the





FIGS. 3 AND 4—TWO VIEWS OF THE BYPRODUCT RECOVERY SYSTEM

southwestern Ohio coal regions were shipped to the university siding. In nearly all cases the coal shipped was run of mine. Out of each carload there was taken a sample amounting to 5 tons for testing, for which the shipper received no pay, the university paying for the rest of it at the prevailing rates. The coals were tested as soon as possible to prevent the weathering changes that affect the quality of coke and gas from the coal.

The 5-ton sample of coal previously referred to is put through a set of Jeffrey rolls, which crush it to about ½-in. size. One ton of this crushed coal is then carefully weighed and hoisted by means of a winch into the bin *O*. All the meters are then inspected to see that they are set at zero, the seals are inspected to see that they are closed, the circulating pump *J* is started and the recording pyrometer *P* is read to be sure that the temperature is satisfactory; the door *Q* at the top of the retort is then opened and the coal slides from bin *O* through shoot *R* into the retort. While the coal is running it is sampled several times, a sample weighing about 10 lb. being obtained. While the coal is running into the retort the water seal in the foul main *C* is drained into tank *S*, where it serves to dilute the ammonia liquors yielded by the coal. As soon as all the coal has run into the retort, doors *Q* and *B* are closed, valve *T* is opened, exhauster *H* is started and valve *U* regulated so that the manometer *V* indicates ⅛ in. of water vacuum and manometer *W* on the foul main indicates 1/10 to ⅛ in. of water vacuum. Thereafter, during the entire run, valve *U* is regulated so as to maintain these vacuums, which are merely sufficient to withdraw the gas from the retort as fast as it is liberated. As soon as gas commences to burn in furnace *I* the motor of the gas calorimeter *M* is started and the calorimeter put into operation by igniting the gas in it by means of a spark plug. At the same time the aspirators of the sulphur train *A* (Fig. 6) and light oil train *E* (Fig. 7) are started and these two determinations proceed continuously during the entire run.

During the 10 to 18 hours which the carbonization of the coal requires, the operator's duties consist merely in seeing that the valve *U* is changed when necessary to maintain the proper vacuum on the retort, that the circulating pump is circulating the sulphuric acid liquor at the proper rate and that the proper excess of sulphuric acid is maintained in the circulating liquor, that the temperature of the retort is properly maintained, that the recording calorimeter, recording meter, sulphur train, light oil train, etc., are properly functioning.

The operator is instructed to regard the test ended when the rate of gas made per hour drops to 300 cu.ft. or when the B.t.u. value of the gas being made drops to 300 B.t.u. net per cu.ft., as it is not likely to be profitable to operate any retort plant beyond this point. It is interesting to note that usually the B.t.u. value drops to 300 at about the same time that the rate of gas making drops to 300 cu.ft. per hour.

When this point has arrived, the operator stops the sulphur and light oil determinations and records their meter readings, records the total volume of gas made and any other special records that are called for, shuts down the circulating pump, closes valve *U* and stops the exhauster, climbs quickly to the top of the retort and opens bridge-pipe door *B* to permit the remaining gas to escape into the atmosphere. It was very essential that valve *U* and all other openings in the by-product system be kept tightly closed until the bridge-pipe in foul main *C* is sealed off with water, as otherwise, owing to the chimney effect of the light coal gas in main *D*, air would be sucked into the system, resulting in an explosion in the foul main. This is quite disconcerting, as it generally blows the water-sealed top of tower *E* off—sometimes hitting the ceiling of the room. The towers *E*, *F* and *G* were designed with loose water-sealed tops to take care of this contingency. However, the explosions never take place if valve *U* is closed before opening door *B* and if thereafter no opening is made in the byproduct system (such, for instance, as might be made if the sulphuric acid solution sump *SS* were drained, exposing the bottom of the tower drains *TD*) until the bridge-pipe in the foul main *C* is sealed by water. (Since these tests the equipment has been changed and some of these operating details no longer apply.)

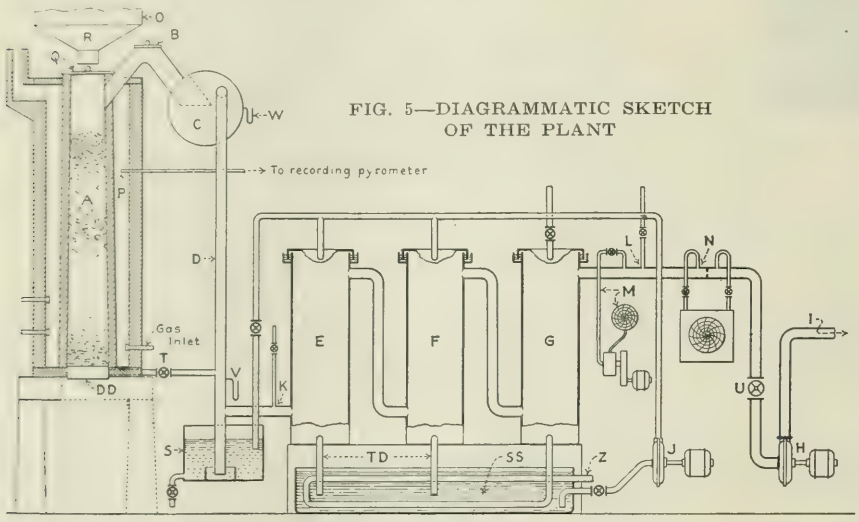


FIG. 5—DIAGRAMMATIC SKETCH OF THE PLANT

The tests were usually started about 8 a.m. so that they were finished before midnight. At this time the operator left for the night.

In the morning the discharge door *DD* at the bottom of the retort was opened and the coke dropped into the steel tank beneath the retort, the tank pulled under the quencher *WQ* and quickly quenched with the well-distributed spray. The tank *QT* when filled to 1 ft. from the top holds just enough water so that when it is all quickly sprayed upon the hot coke, the coke is quenched, but enough heat is retained to dry the coke partly.

While the coke is drying, the tar and ammonia liquor is drained out of the foul main *C* into tank *S*. The main is filled with fresh water. The liquor in the sump *SS* is pumped into tank *S* and the bottom scraped to remove any tar clinging to it. After sufficient time has elapsed to allow the tar and water in tank *S* to separate by gravity, they are drawn off and weighed separately and samples of each set aside for analysis. The coke is then screened through a 1-in. screen, each size being weighed. About 50 lb. of the coke comprising oversize and undersize in proper proportions is weighed, dried and weighed again to obtain the moisture in the coke. The dried coke is then sampled for analysis.

After oiling the motors, renewing the solutions and putting fresh recording charts on the recording instruments, the equipment is then ready for the next run. Under this schedule it was not feasible to make more than one test in 2 days if the tar, ammonia, etc., were obtained from each run. With a larger force a complete run can be easily made each day, and with two shifts two runs could be made in 24 hours.

The methods of chemical analysis used for the coal, coke, tar, ammonia liquor, gas, etc., are the standard methods usually followed by fuel chemists. (See the Gas Engineers' Handbook, Second Edition.) These routine methods will not be described in this article, but it is advisable to indicate somewhat in detail the way in which the "organic sulphur," "light oils" and naphthalene are determined. These determinations are started in the beginning of the run and continue until the test is ended.

As soon as the test on a coal sample is started, the determinations here described are started. For the sulphur determination the aspirator *A* (Fig. 6) draws gas from the main at *K* through the wash bottles *B* and *C*, which remove the H_2S. The gas discharges from the aspirator with the water into the inverted glass tank *D*, thence through meter *E* and into the burner *F*, where it ignites. This burner *F* is inclosed under the chimney *G*, in which is a large supply of ammonium carbonate that slowly vaporizes and passes with the burned gases into the tower *H*. This is filled with broken quartz and down its sides slowly trickles a solution of ammonium carbonate, which accumulates in the vessel *I*, containing all the sulphur of the gas that passes the wash bottles *B* and *C*. Bottles *B* and *C* are filled usually with a NaOH solution, although occasionally a copper sulphate solution is used to remove the H_2S in the gas. Tests show that either solution is satisfactory for this purpose. Therefore, the sulphur in the gas which burns at *F* is only the sulphur which is in thegas combined as CS_2, CH_3S or other "organic compounds" which are difficult to remove in the purifying processes of commercial gas making. The liquor accumulating in *I* is diluted, an aliquot part taken, bromine added, heated, made acid with HCl, boiled and the sulphur precipitated as barium sulphate and weighed. The result is calculated to grains of sulphur per 100 cu.ft. of gas.

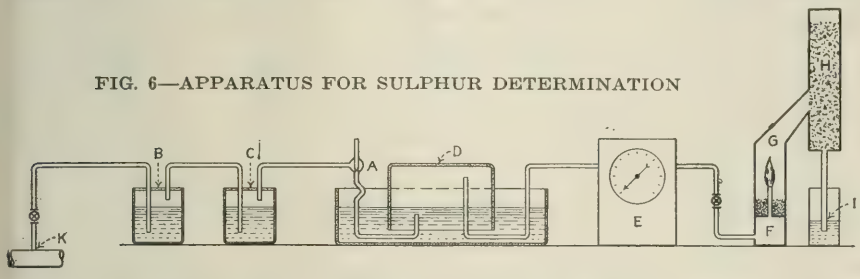

FIG. 6—APPARATUS FOR SULPHUR DETERMINATION

"Light oils" are determined in the gas taken from the main at *L* (see Fig. 7), drawn by aspirator *E* through the NaOH solution in *A*, solid calcium chloride in *B* and the bottles *C* filled with a heavy petroleum oil, and then through the meter *D*. The bottles *C* are weighed before and after the run and the increase in weight in the "light oils."

The naphthalene determination was made by the usual picric acid method on a half dozen samples, the gas being drawn from the main beyond tower *G* (Fig. 5). These determinations all gave practically identical results, showing that the naphthalene in the gases is practically a constant at the temperature of tower *G*, which is cooled by hydrant water. The results average 0.0035 gram per cu.ft., or 5.4 grams per 100 cu. ft.

These results for "organic sulphur" and "light oils" are incorrect in so far as the amount of sample withdrawn per minute was the same throughout the run while the amount of gas made varies from hour to hour. The sample taken should, for strict accuracy, be proportioned to the rate of gas making. The error made is not large, however, and the results are sufficiently accurate for comparative purposes. For the exact work to be published in a later contribution a proportioning meter will be used.

Many coals as they are mined contain so much ash and sulphur that the coke would be quite inferior and, of course, the quantity of gas would be correspondingly reduced. It was decided to wash as many of the coals as time and funds permitted, in order to determine any benefits obtained. A large proportion of the coals received, therefore, had at least three tests made on them —two tests on the coal as received and one test on the washed coal.

The washing was carried on under the direction of Prof. W. A. Mueller of the department of metallurgy and the equipment used was that belonging to the department. The coal was crushed and sized by screening, obtaining two products—through $\frac{1}{4}$-in. mesh and on $\frac{1}{4}$- but through $\frac{1}{2}$-in. mesh. The coarse product was jigged in a full-sized Jeffrey jig and the small-sized product was tabled on a Wilfley table. The purified products from these two operations were dried, sampled and mixed. One ton of the mixed material was weighed and retorted exactly as the raw coal was treated.

The Measurement of Stirrer Performance*

By J. C. Wood, E. R. Whittemore and W. L. Badger

A Method of Measuring Stirrer Performance Is Suggested and Experiments in Which It Has Been Applied to the Ordinary Paddle Stirrer Are Described—The Surprising Efficiency of a Paddle Stirrer Also Is Discussed

THE purposes for which stirrers are used may be analyzed as follows:

1. To mix two or more mutually soluble fluids.
2. To emulsify two or more mutually insoluble fluids.
3. To hold an insoluble solid in suspension in a fluid.
4. To dissolve a soluble solid.
5. To mix two or more viscous, pasty or solid materials.

Evidently the performance of any given device will be different when applied to the various uses above enumerated; and in many cases in practice a given device will be of appreciable value only in one of the cases. Case 4 is perhaps only a special case of case 1, since it consists mainly of removing a film of saturated solution from the surface of the crystals and mixing it with the bulk of the solvent. It is hoped to present a paper soon on this phase of stirring.

The theory of stirring has never been discussed to the writers' knowledge; nor is there in the literature any quantitative data on the performance of any type of stirrer, from either the standpoint of power consumption or time for complete mixing. The writers have no mathematical theory to offer. We believe, however, that the fact that our experimental data seem to be unique gives them importance in spite of the fact that they are purely empirical.

Experimental Methods and Equipment

The tank used in this work was a wood tank about 5 ft. in diameter by 5 ft. high, and held about 600 gal. It was provided with a paddle stirrer (shown in Fig. 1). It had a vertical wood post (3x3 in.) standing in a simple step bearing and rotated by bevel gears and a countershaft. To this vertical post was attached a blade formed of a 3x3-in. timber shaved off at an angle of 45 deg. as indicated. This type of stirrer is very common and is regularly furnished by practically all makers of tanks.

The principal problem was, obviously, to determine when the tank was stirred. Sampling tubes of seamless copper ¼ in. inside diameter were inserted at four levels (1, 2, 3 and 4 ft. from the bottom of the tank) and extended in for three different radial distances at each level.

Figure 1 is a view of the inside of the tank showing these tubes. These proved to be stiff enough to hold their position with the most violent stirring used. They were brought down the outside of the tank and all ended at a common level so that the hydrostatic head on the outlet was the same for all.

At first, methyl violet was used. It was added in the form of a paste in water. Samples were taken from all tubes every 30 seconds and measured in a colorimeter. This was very slow and very trying on the eyes, and the work was greatly delayed by cloudy days. Also occasional tarry lumps of the dye would lodge in the end of one of the sampling tubes and spoil the whole run. This method was therefore abandoned.

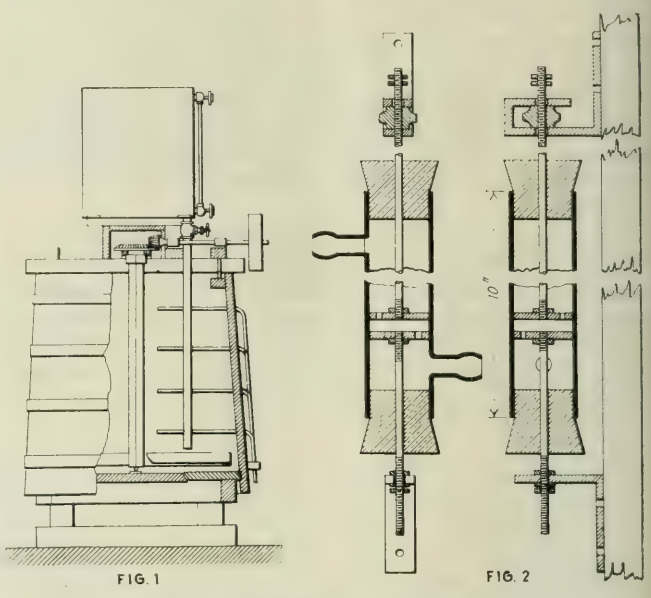

Fig. 1—Arrangement of apparatus
Fig. 2—Details of conductivity cell

Next was tried the addition of strong commercial hydrochloric acid, with titration of the samples. This was also very slow and tedious. It took 4 to 5 hours to make a test and analyze the samples. This preliminary work, however, showed that stirring was quite rapid. Most of the runs indicated a time of stirring of about 1 minute.

The Conductivity Method Finally Adopted

Finally the two junior authors developed a method based on electrical conductivity which promises to have a wide range of usefulness. A number of crude conductivity cells were made, and mounted so that liquid from the sampling tubes could be drawn through them. Several different types were used, but the form shown in Fig. 2 was found to be the most useful. The electrodes were of brass, but with alternating current no troubles were experienced from electrolysis. The position of the upper electrode could be accurately adjusted. In the tests here reported, four or five such cells were connected in series electrically, with a total drop of 220 volts across the set. Through each one was drawn a stream of liquid from one of the sampling tubes, and across each one was connected a voltmeter. The electrodes were adjusted before a test so that all the cells had the same electrical resistance at the start.

The tank was first filled with city water and then a small amount of saturated sodium chloride solution was run in from a storage tank. The amount used corresponded to 4 lb. solid salt per foot of water in the tank. The arrangement (shown in Fig. 1) permitted this solution to be added at the bottom of the tank. The

*Paper presented at the Richmond meeting of the American Institute of Chemical Engineers, Dec. 6 to 9, 1922.

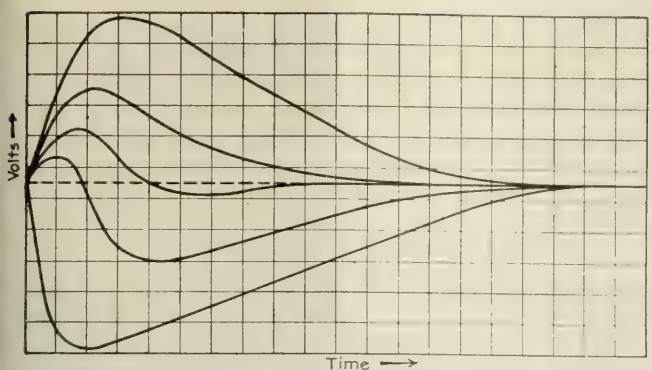

FIG. 3—THEORETICAL VOLTAGE CHANGES

stirrer was then started and readings taken of voltage changes, current, speed and power consumed. The routine was developed to the point where a run with all its data could be made, the tank dumped and made ready for the next run in 10 minutes. A preliminary study showed that the points nearest the center at each level were the last to come to equilibrium with the rest of the tank. Through a large part of this work only four voltmeters were available, and hence the sampling tube at the inner point at each level was used.

Adding strong salt solution to the bottom of the tank should decrease the resistance of the bottom cell and hence decrease the voltage drop across it while increasing the voltage drop across the other cells. As the salt is mixed with the tank contents this resistance should gradually rise to its final value at equilibrium. In the same way, the voltage across the second cell from the bottom should first rise, because, though its resistance had not changed, the decreased voltage drop across the bottom cell should increase the drop across all the others. But when the level of the salt solution rises to the second sampling tube, the resistance of the second cell (and its voltage also) should suddenly drop, with a corresponding increase in the voltage of the cells above it.

Discussion of Results

Theoretical Value of Conductivity

Based on such a line of reasoning, the change in voltage drop across the cells should be as shown in Fig. 3. Actual data from a typical run are shown in Figs. 4 and 5, exactly confirming the theory. Fig. 4 represents a run with water 4 ft. deep, and Fig. 5 one with water 3 ft. deep. In Fig. 4 cell 1 was connected to the center sampling tube 1 ft. from the bottom, cells Nos. 2, 3 and 4 being the corresponding points at the

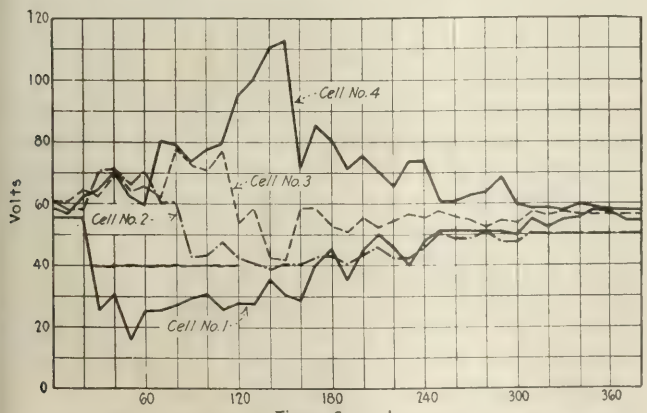

FIG. 4—ACTUAL VOLTAGE CHANGES. 7¾ R.P.M. 4 FT. LEVEL

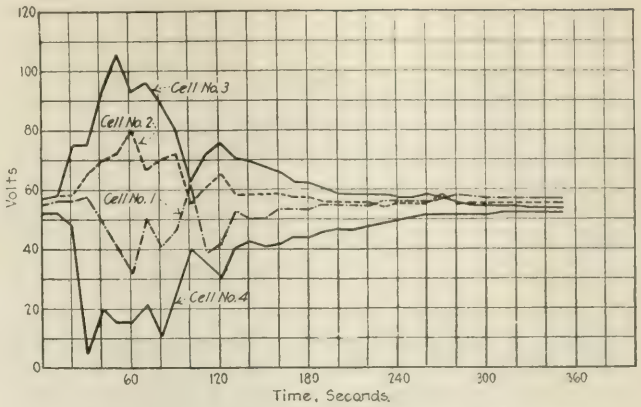

FIG. 5—ACTUAL VOLTAGE CHANGES. 7¾ R.P.M., 3 FT. LEVEL

2, 3 and 4-ft. levels. In Fig. 5 cells 1, 2 and 3 connect to the same tubes as before, but cell 4 was connected to the outer tube at the 3-ft. level. These runs were made with a cruder type of cell than the one shown in Fig. 2 and they could not be accurately adjusted for equal resistance (and hence equal voltage drop).

The way in which the curves of Fig. 4 correspond to our theory is most satisfactory. As strong salt solution is stirred and passes upward, the resistance of the cell suddenly decreases in regular order and the voltage across the rest rises. A most interesting point in Fig. 5 is that the outer *top* cell shows salt before the inner *bottom* cell. This is the result of a centrifugal component of the action of the stirrer, transformed into a vertical current of strong solution by the tank wall.

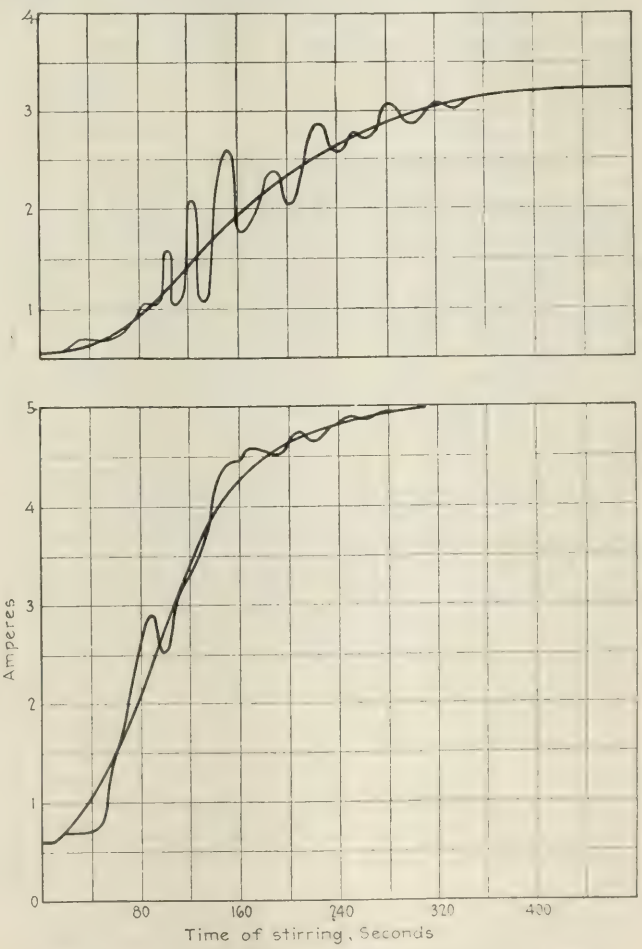

FIG. 6—TYPICAL CURRENT-TIME CURVES, 7¾ AND 10 R.P.M., 4 FT. LEVEL

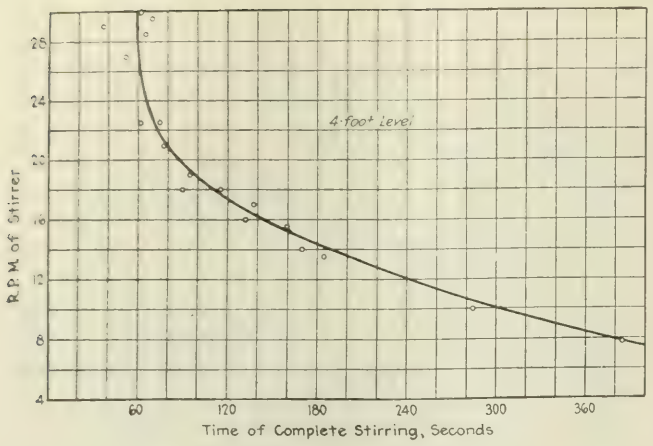

FIG. 7—STIRRER PERFORMANCE

Through most of the work the stirring was so rapid that changes in the voltmeter readings could not be followed. It was observed that the current in the circuit rose and became constant at about the time the voltmeters became uniform. By reading the ammeter every 10 seconds a current-time curve could be plotted, which approached an asymptote parallel to the time axis as stirring became complete. Most of the work was based on this curve. Samples of such curves are shown in Fig. 6. The pulsations in the observed curve represent slugs of strong solution swept past the ends of the sampling tubes by the rotation of the stirrer. A smooth mean curve was put in for purposes of computation. A curve which approaches an asymptote does not give a satisfactory end-point. The first derivative (determined graphically) was plotted for each of the current curves, and an arbitrary end-point taken as the time when $\frac{dc}{dt} = 0.04$ (c = current in amperes, t = time in seconds).

Vertical and Horizontal Uniformity

In the case of runs at the 4-ft. level, when time of stirring was long enough to permit following the voltmeters also, it was found that the voltmeters became constant before the current did. This means that a uniform vertical distribution existed, but that due to centrifugal action there was still a non-uniformity in a horizontal plane. The difference was great enough at very slow speeds to be unmistakable. Hence in all cases the end-point was taken from the curves for current.

From these methods of reading the curves of Figs. 7 and 8 have been plotted. The determinations of Fig. 7 were made with the tank filled with water to a depth of 4 ft., and those of Fig. 8 to a depth of 3 ft. The most striking thing about these curves is the short time

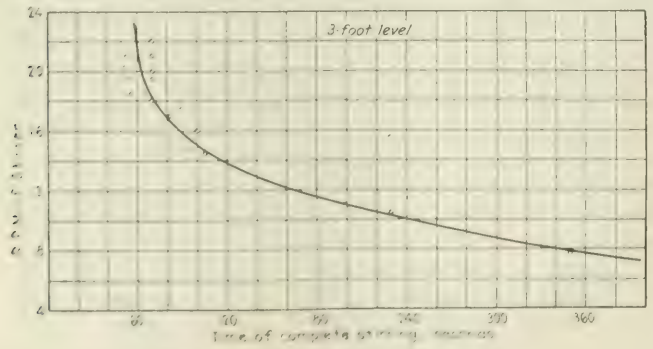

FIG. 8—STIRRER PERFORMANCE

necessary to mix this tank thoroughly with what would ordinarily be considered a very inefficient stirrer. The second point is that an increase in speed for this stirrer above 18 to 20 r.p.m. is useless so far as time of stirring is concerned. In fact in the vicinity of 30 r.p.m. there seems to be a break in the curves, and at rates above this mixing seems actually slower than below this speed.

The Illusion of Visible Swirl

Another feature that does not appear in the experimental data but which is interesting is that at all speeds the contents of the tank seem to be rotating as an even, homogeneous mass. The advocate of some special type of stirrer would insist that the contents of the tank were not being stirred at all. There was no visible swirling, eddying, churning or other indications of crossing of lines of flow. That this type of motion may produce very rapid and efficient mixing is a new thought in stirrer design. One needs but to consider the *apparent* motion of a fluid in a transparent tube at velocities above the critical. Small visible suspended particles move, apparently, in straight lines; yet the flow may be fully turbulent. Visible motion is due to particles of suspended solids which may very well have inertia

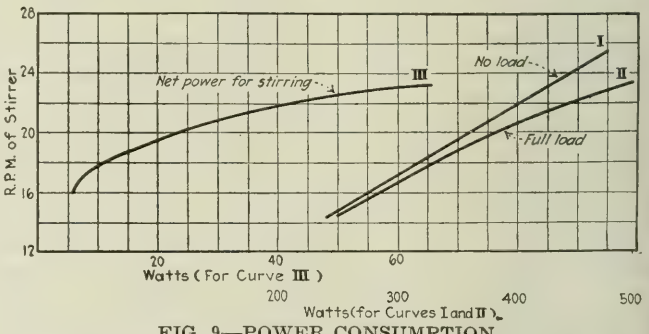

FIG. 9—POWER CONSUMPTION

Curve I, no load. Curve II, full load. Curve III, net power for stirring.

enough to flow in fairly straight lines in spite of the fluid turbulence around them. So in mixing two mutually soluble liquids (as salt solution and water) the visible motion of the mass is not an index of the true degree of turbulence.

Measurements of power consumed were not satisfactory. So much power was consumed in shafting, belting, gears, etc., that the power actually used for stirring was too low to measure for the slower speeds. Power measurements were simplified by the fact that a d.c. motor was used. Shunt field power was determined once and considered constant (as the control rheostat did not affect the voltage across the shunt coils). Power in the armature was determined from a properly connected voltmeter and ammeter in the armature circuit. A power reading was taken at a given speed with the tank empty, and again at the same speed with the tank filled with water to the desired height. The difference was considered the net power consumed in stirring. At slow speeds it was so small as to be less than errors introduced by fluctuations in the instruments. Such data as were determined are shown in Fig. 9. Here curve I is the no-load power consumption, curve II the full-load power consumption, and curve III the net power for stirring. This indicates clearly the very small amount of power really used at any reasonable speed and the relatively rapid increase in power at higher speeds. The point where a rapid rise of power consumption occurs without a perceptible increase in time

of stirring is one of the useful results to be obtained by applying this method of analysis to the stirring device.

Studies are now under way on rate of dissolving crystals and on the characteristics of propeller stirrers.

Conclusions

1. A plain paddle stirrer is a much more efficient mixer for miscible liquids than is usually supposed.
2. For the conditions of this set of experiments, a 600-gal. tank was thoroughly stirred in less than 1 minute at any speed above 22 r.p.m., though above 30 r.p.m. there seemed to be an increase of stirring time.
3. The visual appearance of a tank of liquid being stirred is not a measure of the efficiency of the stirring apparatus.
4. At the speed above which there is no gain in time of stirring, there is a rapid rise in net power consumption.

Gas in Steel for Welding

About two years ago, according to the August, 1922, number of *Oxy-Acetylene Tips*, a trade publication of the Linde Air Products Co., a certain tube manufacturer reported welding troubles, which upon investigation seemed to be confined to a certain shipment of steel. Welds made on these strips in regular production were very brittle and had a rough outer surface. It appeared impossible to get a good weld with this material, and samples of it, together with some of satisfactory material, were critically examined at the company's research laboratory in Long Island City. Strips of the steels were connected up like blowout fuses in a vertical line, and a 12-volt current of high amperage was passed through the series until the strips began to melt at their centers. The current was then switched off, and the strips were closely observed in the process of cooling.

The good steel cooled off without any decided change in appearance, excepting a rounding off at the edges. The bad steel puffed and sparks were thrown off, an action that had been observed and reported in connection with the unsatisfactory welding of the metal at the tube company's plant. After the cooling had proceeded for some time the sample was found to be pitted with little holes and craters of larger dimension.

These results have been reported to the American Welding Society, and that organization is using the studies in a campaign designed to educate its members on the desirability of using only sound, gas-free metal for their welding operations.

Chinese Market for Chemicals

China is becoming an increasingly important market for chemicals, says Commercial Attaché Julean Arnold. Local manufacturing plants are springing up in connection with the production of certain commercial chemicals, which compete with the foreign products in some lines to such an extent as to reduce the trade materially. This is especially true of sulphuric, hydrochloric and nitric acids.

Details of the quantities of these various chemicals imported are lacking, official Chinese returns combining most of them under the head, "chemical products (not including match-making materials, medicines and soda)." Net imports of this group in 1921 were valued at 2,817,964 haikwan taels, against 2,291,203 taels in 1920. Match-making materials (except paraffine wax) were imported in 1921 to the value of 2,281,181 taels, compared with 1,893,670 taels in 1920; medicines (including cocaine and morphia), 7,056,080 taels, against 6,790,230 taels. In addition, were imports of glycerine valued at 93,280 taels, against 106,213 taels; soda, 1,775,509 taels, against 2,308,669 taels; and explosives for industrial purposes, 174,619 taels, against 237,723 taels.

Similarity of Results in Patent and Secret Process May Justify Conclusion of Infringement

A patent and a secret process conflict in the case of A. B. Dick Co. versus Barnett is decided in the United States Court of Appeals, 277 Federal, 423. The federal District Court granted a preliminary injunction against the defendant preventing his sale of "Hesco" stencil paper, which is alleged to be an infringement upon the plaintiff's Fuller patent, No. 1,101,268.

Plaintiff owns patents covering the process and the product of plaintiff's so-called indestructible mimeograph stencil paper "Dermatype." These patents have been sustained in prior suits, therefore it was quite proper to assume their validity in the present suit on motion for a preliminary injunction, says the court. The contest then was as to infringement of them by defendant's acts.

This controversy turns on the construction to be given the claims in suit. Defendant contended that they were limited to a fully and permanently coagulated (insoluble) gelatin, and that the defendant's coating was almost entirely soluble. The experts were in conflict as to the true scope of the claims, as well as the nature of the plaintiff's process and its resultant product. The trial court recognized that whether the defendant used "a fully coagulated substance" or "a coagulated collodial substance" or their equivalents, within the meaning of the claims in suit, was a debatable question.

In reversing the order granting a preliminary injunction against the defendant by the District Court the Court of Appeals says that while plaintiff must demonstrate infringement, similarity of result may justify a conclusion of infringement, in the absence of proof that in some respects the secret process (which need not, however, be disclosed) or the resulting product differs from the patented process or product. Here, however, the affidavits of the expert and of the "Hesco" manufacturer, while guarding the secret process, purport to show important differences. Without passing upon their sufficiency, they raise at least a reasonable doubt as to infringement. The rule of law laid down and applicable here is that to justify a preliminary injunction in a patent case plaintiff has not merely the burden of proof but must "establish a *prima facie* case free from reasonable doubt."

For while ordinarily a preliminary injunction aims to preserve the *status quo* pending suit, in a patent case like this it may destroy it, says the court.

Equilibrium Diagram Of the Iron-Carbon System*

By Kôtarô Honda
Bessemer Medalist

Metastable or Graphite Lines Are Rejected, the Solidus Redrawn, A_4 or Delta Iron Fields Are Introduced—A_2 and A_0 Represent No Changes in Phase, but Are Traced Across the Diagram

MANY important investigations of the properties of the alloys of iron with carbon have recently been made, and the constitutional diagram of iron and carbon must be modified in some important points.

Some metallurgists believe that graphite always results from the breaking up of cementite soon after its solidification owing to its instability at very high temperatures. From the mode of occurrence, other metallurgists contend that it is a product directly separated from the melt, the graphitization taking place more easily in proportion as the rate of cooling through the solidifying range is smaller, and they propose the so-called double diagram representing the stable and unstable equilibriums.

Graphitization

According to the result of recent investigations by Dr. T. Murakami and the present writer,[1] graphite in cast iron is not a product directly separated from the melt, but is produced in the range from 1,130 to 1,050 deg.—that is, the graphitization always takes place after the solidification of the melt. This result was obtained from quenching experiments at very high temperatures. Thus the double diagram as given in many text-books of metallurgy is not correct, in agreement with Sauveur's view.

The question whether the liquid iron-carbon alloys contain carbon as graphite or as cementite has an intimate connection with the two theories of graphitization above referred to. Dr. Murakami and the present writer cooled the liquid alloys at different rates, or quenched them in a thick iron mold having a narrow hole, 2 mm. thick, 3 cm. wide and 6 cm. deep. This mode of quenching the melt was more effective than quenching in water. The quicker the rate of cooling the less the degree of graphitization. By quenching in the iron mold, even hypereutectic alloys approaching to the concentration of pure cementite do not graphitize at all.

These results show that in a liquid state carbon exists in the combined state, otherwise quick cooling will cause a greater degree of graphitization. If this conclusion be correct, it is very natural to conceive that the first product of solidification is cementite.

The formation of graphite is not a direct decomposition of cementite by equation

$$Fe_3C = 3Fe + C$$

but it is due to a catalytic action of gases, such as carbon monoxide or dioxide. The mechanism of this catalytic action is not yet certain, but the following assumption will not be far from the fact: As the temperature of the specimen falls from the melting point, a minute quantity of free carbon dioxide coexisting with carbon monoxide soon reacts on cementite and produces carbon monoxide by equation

$$Fe_3C + CO_2 = 2CO + 3Fe$$

This diminution or disappearance of free carbon dioxide causes a further dissociation of carbon monoxide

$$2CO = CO_2 + C$$

reproducing the dioxide, which again reacts with cementite. Thus, if there is in the metal a small quantity of free carbon monoxide, these two reactions are continuously repeated, and graphite is gradually produced with the consumption of cementite. The most favorable temperature for the graphitization is just below the eutectic point, 1,130 to 1,100 deg., but as the temperature falls, graphitization becomes less.

Thus, since graphitization always takes place after the solidification of the melt, the graphite lines in the double diagram must be omitted.

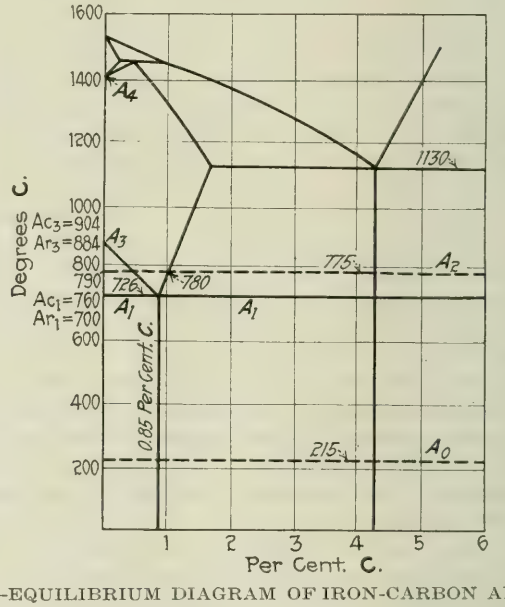

FIG. 1—EQUILIBRIUM DIAGRAM OF IRON-CARBON ALLOYS

In the recent diagram of the iron-carbon system, the solidus is usually shown as a curve bending considerably downward. But it can be shown by thermodynamics that if the liquidus is straight or slightly curved, the same must also be true for the solidus. Hence in my constitutional diagram (Fig. 1), the lower portion of the solidus is slightly bent upward.

A_4 or γ-δ Transformation

This is an allotropic transformation characteristic of pure iron; it was first observed by Osmond[2] thermally, then by Curie[3] magnetically, and afterward by others. The mean values of the recent measurement for Ar_4 and Ac_4 points are 1,400 and 1,410 deg. C. respectively. Ruer and Klesper[4] found that A_4 rapidly rises with the increase of carbon, and that at 1,486 deg. C. the melt

with 0.38 per cent carbon is in equilibrium with γ- and δ-irons of the concentrations 0.18 and 0.07 per cent carbon respectively.

The recent progress of X-ray analysis has revealed the actual configuration of atoms in α- and γ-irons; but owing to the difficulty of experimenting at the high temperature, the determination of the atomic configuration in δ-iron has not yet been made. Judging from its physical properties, however, it seems to me very probable that the space-lattice in δ-iron is a body-centered cube as in α-iron.

A_3 or α-γ Transformation

This is a well-known allotropic transformation characteristic of pure iron; the transformation point during heating (Ac_3 point) is 904 deg. C., and that during cooling (Ar_3 point) 884 deg. C. With the addition of carbon in iron, this point falls quite continuously, till it reaches the eutectoid horizontal or A_1 line at a concentration of 0.85 per cent C.

By X-ray analysis, it is found that γ-iron possesses a space lattice of a face-centered cube.

A_2 or Magnetic Transformation

This transformation is sometimes called the α-β transformation. On several occasions[5] I have shown that the A_2 transformation in pure iron is a progressive change beginning from the lowest temperature and ending at about 790 deg. C., its rate of change increasing with the rise of temperature. This progressive change, as revealed by its magnetic property, is clearly seen from the magnetization - temperature curve in a strong field (Fig. 2). Though the temperature is kept constant in the transforming range for a sufficiently long period of time, the magnetization—that is, the transformation—does not progress with time.[6] In other words, the internal change corresponding to the A_2 transformation is a definite function of temperature, unlike allotropic transformations, such as A_3 and A_4, in which the change takes place at a definite temperature, provided a sufficient time is allowed. Hence it is not appropriate to consider the A_2 transformation as an allotropic change of phase.

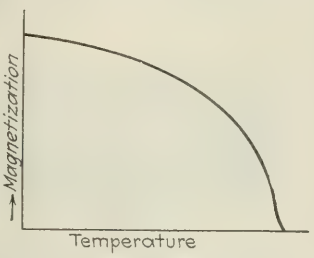

FIG. 2—MAGNETIZATION-TEMPERATURE CURVE OF PURE IRON IN A STRONG FIELD

The A_2 point as determined thermally is usually taken as 768 deg. C.; this is the temperature at which the rate of heat evolution or absorption is a maximum by cooling or heating respectively, and somewhat lower than 790 deg. proposed by the present writer. This latter is that at which the transformation begins on cooling or terminates on heating; it is the temperature at which iron changes from the ferromagnetic to the paramagnetic state. Since the change gradually takes place in the whole range of temperature below the A_2 point and every temperature in this range has the same quality with respect to the transformation, it is obviously not correct to call a temperature, 768 deg. C., at which the rate of change is a maximum, the A_2 or critical point or range.

According to the result of X-ray analysis,[7] below the A_3 point, iron has always the space lattice of a body-centered cube, which is in complete agreement with the view above given. There is thus no β-iron as an independent phase. The A_3 transformation during heating is then atomistically the change of the atomic configuration in iron crystals from a body-centered to a face-centered cube.

It remains to explain what is the nature of the progressive change in the A_2 transformation. According to the theory of Dr. J. Okubo and the present writer,[8] the gradual diminution of magnetization with the rise of temperature is due to the increasing velocity of rotation of the atoms about their magnetic axes. The angular velocity of this rotation is assumed to be comparatively small at room temperature, and the gyrostatic resistance to the turning of the magnetic axes of the atoms in the direction of the field is very small. But as the temperature is continuously increased to a very high degree, the angular velocity, by virtue of thermal impact among atoms, always becomes greater, and hence the gyrostatic action of the atoms rapidly increases, the substance becoming thereby less and less magnetizable, till magnetization vanishes. When the field ceases to act, the magnetic axes of atoms take random directions by virtue of thermal impacts. Thus in this theory, the A_2 transformation is of the progressive nature and the change will obviously be a definite function of temperature, as actually observed. The heat absorbed during Ac_2 transformation is the energy required to increase the angular velocity of the atoms, while the heat evolved during Ar_2 transformation is the energy of rotation liberated.

The A_2 points in pure iron during heating and cooling exactly coincide with each other, their value being 790 deg. C. According to the accurate magnetic determination of Ishiwara,[9] with the addition of carbon to iron, the Ac_2 point continuously falls to 780 deg. C. at about 1 per cent carbon and afterward remains nearly constant. Up to 0.5 per cent carbon, the Ar_2 point nearly coincides with the Ac_2 point, but afterward the former falls gradually below the latter, and at 4 per cent carbon, the difference amounts to 25 deg. C. Thus above the eutectoid points, the iron-carbon alloys are still ferromagnetic, though weakly so. Taking the mean of these two sets of values, the A_2 line beginning at 790 deg. continuously falls to 780 deg. at 1 per cent carbon and to 775 deg. at 4 per cent. Since the A_2 transformation is not the change of phase, the A_2 line is dotted.

From the above result, we conclude that above the eutectoid concentration the A_2 and A_1 points merge into a single point, but the A_2 point does not do so, as is usually believed to be the case.

Recently Ruer[10] observed in the heating curve of a cast iron (3.85 per cent C), a break at a point higher by 10 deg. than the cementite eutectoid point and took it for the graphite eutectoid; but according to the writer's view, it is attributed to the last part of the A_2 transformation, ending at the Ac_2 line.

A_1 or Eutectoid Transformation

This is the transformation characteristic of steel or cast iron. During heating the transformation takes place at 760 deg. C., but during cooling at 700; this is the

[10] *Z. anorg. allgem. Chem.*, vol. 117 (1921), p. 249.

temperature at which cementite dissolves in iron or separates from it. Theoretically the A_1 line must be horizontal, extending to the concentration of cementite; but it actually rises slightly at higher concentrations of carbon, the maximum increase being 20 deg. This increase is very probably due to the presence of silicon in these alloys as impurities. For it is well known that silicon raises the A_1 point of steel, and though in these alloys the quantity of silicon present does not differ much, yet the ferrite in which it dissolves continuously diminishes as the carbon increases, being zero at the concentration of cementite. Hence the concentration of silicon in ferrite steadily increases as carbon increases, and hence the A_1 point is raised. On the other hand, manganese is known to depress the A_1 point. Hence as the quantity of silicon present as impurities is greater and that of manganese smaller, the rise of the A_1 point is greater. In my ideal diagram of the iron-carbon system, the A_1 line is drawn horizontally.

Considered from the point of view of the microstructure, the A_1 transformation consists in

$$\text{Austenite} \rightleftharpoons \text{pearlite}$$

but as I have reported in other papers,[11] the above equation represents only the result—not the process itself. According to the writer's view, the process takes place in the order of

$$\text{Austenite} \leftrightharpoons \text{martensite} \leftrightharpoons \text{pearlite}$$

that is, during cooling, at the A_1 point the austenite changes to pearlite through martensite, and during heating the reverse change takes place. It should be here remarked that at the ordinary A_1 point, as soon as martensite is formed, it is immediately changed into pearlite or austenite, and hence in the case of equilibrium the martensite does not actually come into existence. Hence in the equilibrium diagram the martensite line ought to be absent It is only in the case of quenching or non-equilibrating transformation that the martensite is formed and, being formed, remains undecomposed.

Some metallurgists[12] object to the double reaction above mentioned, as contradictory to the phase rule, but they have misunderstood the meaning of the above reaction.

A_0 or Cementite Transformation

This is the transformation characteristic of cementite; it is in its nature the same transformation as the A_2 transformation in iron. The transformation is progressive and extends from the lowest temperature to 215 deg. C., the change being a definite function of temperature. During heating or cooling the transformation terminates or commences at the same temperature (215 deg. C.), the A_0 point. This point is observable for all alloys containing free cementite, and has always the same value. Since the transformation is not a true change of phase, in the constitutional diagram the A_0 line is drawn as a dotted horizontal line like the A_2 line.

Conclusion

To sum up, the constitutional diagram is greatly simplified on the one hand by the omission of the graphite line, and on the other by that of the β-iron line, that is, by introducing the dotted A_2 line. The A_0 line is newly added.

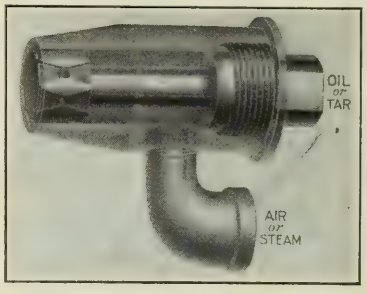
The Hauck Oil Burner

A New Appliance for Chemical and Metallurgical Heating Furnaces

THE Hauck Manufacturing Co., of Brooklyn, N. Y., has recently placed on the market a new and improved type of atomizer for burning fuel oil and distillate. This burner consists essentially of a cylindrical casing with slots parallel to the axis of the bore. These slots form with the inner wall of the casing longitudinal ports through which the atomized oil is impelled into the furnace. The ports are constructed in the form of a small Venturi tube, being constricted at the center portion and flared at both ends. At the throat or constricted portions of the orifice are radial openings which connect to the bore of the burner.

The material which is to be used for fuel is delivered to the burner through this central bore at a pressure of from 40 to 60 lb. per sq.in. It flows from the central bore through the radial openings into the restricted portions of the orifices.

The compressed air or steam which is used for atomizing is delivered to the burner at a pressure of about 80 to 100 lb. per sq.in. It flows longitudinally through the Venturi port opening, so that as it passes the constricted part of the opening its velocity is at the highest point. At this point it picks up the oil or other fuel which is delivered under pressure through the radial openings to the tube. It may be said to blast the oil and thus deliver it in the atomized or foglike form, which best promotes combustion.



It is claimed for this burner that it secures a thorough mixture of the air and fuel at the mouth of the burner. It is claimed also that it correctly proportions the air or steam to the oil, that it is accessible for purposes of inspection and that it can be conveniently removed from the furnace without affecting the operation of any other burner served by the same system.

Further advantages claimed for it are that reducing, neutral and oxidizing flames are readily obtained by the mere manipulation of the oil and air valves. This enables the operator to control closely the furnace atmosphere at the least expenditure of attention and labor. Another advantage claimed is embodied in the fact that combustion can be made to take place close to the burner nozzle, thus preventing oxygen from coming into contact with other portions of the furnace and reducing the amount of scaling. Another result of this lack of oxygen in the furnace atmosphere may be found in the reduction of spoilage and greater uniformity of the product obtained.

Instantaneous Measurement of High Pressures

Plates properly cut from quartz crystal liberate an electric charge when subjected to pressure. A stack of these plates in a small steel container is subjected to the pressure to be measured and the charge which is liberated passes through a special type of galvanometer. The galvanometer movements are photographed on a rapidly moving film.

Book Reviews

LABORATORY MANUAL OF COLLOID CHEMISTRY. By *Harry N. Holmes*, Professor of Chemistry in Oberlin College. John Wiley and Sons, Inc., New York; Chapman & Hall, Ltd., London, 1922. xii + 127 pp. 32 figs. 23.5x15 cm.

A "brief bibliography" of thirty-four titles of books dealing with the manifold theoretical and practical aspects of colloid chemistry, tabulated in pages 119 to 121 of this volume, indicates the considerable attention now paid to this important topic. In a field to which so many new workers are being continually attracted, it is obviously desirable to have an authoritative guide on experimental technique and methods. Previous manuals, such as Svedberg's "Herstellung Kolloider Lösungen," have covered only portions of the ground, usually for the benefit of more advanced workers. The need for a general laboratory outline of the subject, suitable for student use, has long been seriously felt, and the present volume has been prepared by Professor Holmes, at the request of the colloid committee of the National Research Council, to fill the gap.

In successive chapters the following subjects are developed: I, Suspensions—Coarse and Fine; II, Dialysis and Diffusion; III, Condensation Methods of Preparation; IV, Dispersion Methods of Preparation—Peptization; V, Coagulation; VI, Protective Colloids; VII, Solvated Colloids; VIII, Surface Tension; IX, Emulsions; X, Viscosity; XI, Adsorption From Solution; XII, Adsorption of Gases; XIII, Reactions in Gels; XIV, Experiments With the Ultramicroscope; XV, Soils and Clays; XVI, Special Topics. Altogether, no fewer than 186 experiments are outlined. No one student, of course, can be expected to perform all of these, and representative selections fitted for special courses are suggested in the introduction.

The book as a whole must be very highly commended. The directions, in general, are given in sufficient detail to enable the beginner to understand the purpose of each experiment and to take all precautions necessary to obtain the desired result, without being so full as to destroy his initiative. Much of the subject matter, of course, is intimately related with Professor Holmes' own research topics. A number of experiments have also been contributed by investigators well known in their particular fields, including W. D. Bancroft (on dyeing), S. E. Sheppard (on gelatin) and J. A. Wilson (on tanning). The greater part of the chapter on Adsorption of Gases is taken up with the work of Patrick on silica gels. With such a galaxy of experts, few errors of commission (and certainly none of omission) are to be expected. The relative space devoted to the work of Fischer and of McBain on soaps (pp. 35-39) might be reversed with considerable profit to the reader, and the purely empirical nature of the Freundlich adsorption equation (pp. 72-73) should certainly be emphasized, but these are minor points.

A more serious criticism that can be offered is that the author tends, in common with many of his colloidal colleagues, to exaggerate the scope of his special subject, and to inflate it unduly by including topics which properly belong elsewhere. It is a moot question whether adsorption ought to be included in colloid rather than in general physical chemistry, even though long-established custom in this case argues for its retention. To regard an experiment such as the catalysis of the reaction between carbon monoxide and oxygen by means of "hopcalite" (p. 110) as an application of colloid chemistry, however, is almost Ostwaldian.

Teachers of colloid chemistry will undoubtedly find this volume of the greatest assistance to them in the development of their laboratory courses. The frequent references to the original literature should prove a source of inspiration to the research worker, as well as to the student entering the subject for the first time.

JAMES KENDALL.

THE STEEL FOUNDRY. By *John Howe Hall*. Cloth 6x9 in. 334 pp. McGraw-Hill Book Co., Inc., New York, 1922. Price, $4.

Mr. Hall tell us that he has aimed at setting forth the metallurgy of the steel foundry from the point of view of the steel foundry engineer who is interested in securing a product of high quality at the lowest cost commensurate with this quality. The result is a readable and valuable book with a range extending considerably beyond the steel foundry proper.

The various processes of steel making are dealt with: crucible; acid and basic electric; acid and basic open-hearth, and bessemer, side-blow and bottom-blow. These are considered first in the light of their availability for the manufacture of steel castings, judgment being passed on the following points: Market, including quality, style of casting to be made, cost of production, tonnage in sight; raw material and fuel available; capital available; competition; labor available, and uniformity of operation. Mr. Hall states fairly the advantages and disadvantages of each process and gives estimates of cost for installation and operation. If there is such a person as a foundry engineer undecided as to the process to be chosen for a proposed foundry, he will find indicated here his proper course of reasoning.

This preliminary survey of methods of steel making is followed by a detailed account of the methods of operation for each process. To the foundry engineer who wishes to extend and consolidate his knowledge of the fundamental process on which his craft depends, this treatise on steel making will be interesting and useful. It takes up, however, over two-thirds of the book, leaving only one chapter, less than one-sixth of the book, for molding, pouring and digging out, with the same space for heat-treatment and annealing, and only four pages for finishing, straightening and welding.

With this division of space it is evident that the art of the steel-foundryman is but briefly treated. We should have liked to see Mr. Hall reverse the proportions of his dosage and apply his wide knowledge of the steel foundry to giving a more complete analysis and exposition of the steel-founder's craft.

One point which requires further consideration is his statement that cracks are favored by low carbon, an analysis which gives the maximum shrinkage. In order to make the matter complete, mention should be made of the fact that in castings of heavy section the change of volume while passing through the critical range may have an important influence on cracking. The matter is undobtedly complex and deserves detailed consideration. Let us hope that an early call for a third edition will give Mr. Hall occasion thus to increase our indebtedness to him.

The present tendency to increase continually the intricacy of the forms of steel castings would make a thorough study of the principles of molding and casting of great value. Not only would this be of direct aid to the foundryman, but it would help him in enlightening those for whom he works—the designers of steel castings. The manager of a successful steel foundry recently expressed the hope that a particularly warm corner of the hereafter would be reserved for the designers of modern steel castings for locomotives. It would be a pleasant thing to have a treatise on foundry practice to offer as a shorter catechism to save these brands from the burning. Full utilization of the possibilities made available by progress in the art of casting steel can be attained only by having considerable knowledge of the difficulties and the limitations of the art. This phase of the subject is somewhat neglected by Mr. Hall. What he gives makes us wish for more.

LAWFORD H. FRY.

HANDBOOK OF PETROLEUM, ASPHALT AND NATURAL GAS. By *Roy Cross*. 625 pp. Published as Bulletin 16 of Kansas City Testing Laboratory (Kansas City, Mo.). Price, $7.50.

Those in the petroleum industry who in the past have profited from the usefulness of this bulletin's predecessors will need no elucidation of its purpose. Others may be interested in the prefatory note to Bulletin 15: "The purpose of this publication is to set forth in concise form for the petroleum producer, seller, refiner and technologist the scientific information and statistics on the production, properties, handling, refining and methods of evaluating petroleum and related products." In addition to the sort of material usually found in handbooks, the technical man will find of value the descriptive chapters on petroleum refining, including

cracking, transportation, storage and gaging, general and chemical constitution of petroleum as well as the standardized and commercial methods of analysis. In the chapter on refining the author includes a detailed description of the decomposition of petroleum hydrocarbons in the presence of aluminum chloride. This review of the subject, together with the list of important references, is a real contribution to the literature.

Other new matter appearing in this bulletin includes tables and formulas for gaging the capacity of horizontal cylindrical tanks with "bumped" ends, methods for determining the capacity of oil pipe lines, details of refining and cracking costs, specifications and properties of petroleum products and the vapor volumes of distillates of different gravities at varying temperatures. A feature worthy of mention is the compilation and classification of United States patents on petroleum processes from 1850 to January, 1922.

The handbook is attractively bound in a black flexible cover and by means of its loose leaf binding it is possible to insert such new matter as is occasionally issued by the publishers.

S. D. KIRKPATRICK.

HANDBOOK OF CHEMICAL ENGINEERING. Prepared by a staff of specialists. *Donald M. Liddell*, editor-in-chief. 2 vols. Published by McGraw-Hill Co., New York. Price $8.

A pioneer book is always an experiment and its success depends upon many factors. The reviewer is concerned with only two of them. First, is it a good book and second, is it well printed? Now the "Handbook of Chemical Engineering" is well printed, but I promised myself the satisfaction of protesting against the occasional and apparently unnecessary transition from large to small type at various points in the text.

This book had a hard job when it came to my desk. It had been heard of some time ago and was being awaited with interest, so it had to take a rather stiff hurdle of standard. The Lord knows, and every chemical engineer knows, that it was needed badly. Before we go any further I want to make one thing clear. The book is a milestone in chemical engineering. It is not only a milestone, it is a splendid work and a real achievement. I read it, enjoyed it, found much profit in it and intend to keep it for reference.

If you were faced with the task of compiling a handbook of chemical engineering, what would you do? The reviewer would have done exactly what Mr. Liddell did—"analyzed chemical industries and selected the features essential to most of them for description." Thus the selection of subjects would be the first bone of contention, and so we shall discuss that first. Here is Mr. Liddell's list in the order in which they appear:

I, Generation and Transmission of Power. II, Material Handling—Transportation of Solids. III, Transportation of Liquids. IV, Transportation of Gases. V, Crushing and Grounding. VI, Grading (Sizing and Screening). VII, Mechanical Separation. VIII, Concentration. IX, Leaching and Dissolving. X, Evaporating and Drying. XI, Crystallization. XII, Thermometry and Pyrometry. XIII, Refractories. XIV, High-Temperature Production. XV, Mixing and Kneading. XVI, Sampling. XVII, Fermentation. XVIII, Distillation, Fractional and Destructive. XIX, Refrigeration. XX, Oxidation and Reduction. XXI, Electrochemistry. XXII, Catalysis. XXIII, Colloidal Chemistry. XXIV, Smelting —Zinc — Lead — Copper — Iron — Roasting. XXV, Lutes and Cements. XXVI, Radioactive Elements. XXVII, Rare Metals. XXVIII, Rare Gases. XXIX, Materials of Construction. XXX, Plant Design. XXXI, Method of Financing.

Comprehensive! That is the first reaction. Thus it would be for sins of commission rather than those of omission that the editor might be liable. That is in itself a recommendation. Every subject is there that should be, but there are some subjects which are not extremely relevant to chemical engineering. It is difficult, perhaps impossible, to draw the line, and much better to include than omit. The editor's predilection for metallurgy has given somewhat elaborate treatment to certain subjects which are of primary or sole interest to the metallurgical engineer. Chapter VIII, on Concentration (in the metallurgical sense), and Chapter XXIV, on Smelting and Roasting, are examples. It is perhaps a legitimate query whether a handbook of chemical engineering should carry these subjects. So too the treatment of Mechanical Separation (Chapter VII) and of Sampling (Chapter XVI) have a distinct metallurgical balance. A different emphasis would have been better. Again, Chapters XXVI and XXVIII, on Radioactive Elements and Rare Gases, are defended by the author specifically, but while the essays are most interesting, I question their inclusion under chemical engineering.

Finally, Chapter XXXI, on Methods of Financing, is a correct gesture in that it emphasizes the necessity of familiarity with the "business side of chemical manufacturing," but it is only one of half a dozen equally important subjects, all of which should be discussed if that phase is to have emphasis. It could have been omitted without diminishing the value of the book as a handbook of chemical engineering, and should have been omitted.

Perhaps it is also legitimate to suggest that future editions would be improved by a grouping of subjects under several general headings which suggest themselves. The present order of discussion is rather random when it does not need to be.

It is inevitable that with thirty-one contributors, the points of view toward subjects will vary with temperament and experience all the way from theoretical thermodynamic treatment to scientific co-ordination of practical data. In general the treatment is distinguished, as would be expected from the high caliber of the contributors. But the fact that one rather expects some variation in method of treatment does not eliminate a cretain disappointment at the unevenness. The editor himself has handled his subjects splendidly, almost ideally. In some of the articles there is an unfortunate lack of contact with plant practice. The authors treat the subject adequately from a theoretical standpoint, but when it comes to giving the basis for making plant installations they fall down. This is the exception, however, for in general the treatment of this phase is able and there is focussed on the many subjects an almost unique experience in that field.

It is not inappropriate for us to evaluate some of the chapters where this evaluation will be instructive. The Generation and Transmission of Power is a very meaty article. Perhaps the subject lends itself better than some to a quantitative study, but it is of unusual value and interest. The next three chapters, on the Transportation of Solids, Liquids and Gases, are likewise substantial. Perhaps the discussion of Oxidation and Reduction is more disappointing to the technical man than any other. A very adequate theoretical discussion but no technological information is given and such an important oxidizer as manganese dioxide is not even mentioned. In happy contrast is the next article, on Electrolysis (by the editor himself). It is a fund of invaluable information about plant practice. Catalysis is excellently treated, while Colloids, though interesting, is filled with much irrelevant material and there seems to be a desire on the part of the author to make you say "Oh, my!" Fractional Distillation is discussed from a theoretical standpoint and the reader would find a good deal of trouble in building a still from the data offered. The chapter on Plant Design escapes more than half the problem by conveniently distinguishing between machine design and plant design. The discussion of the economics and geography of the subject is interesting but not nearly as vital as the discarded half of the subject. There are many plants which have violated every principle developed in the article and still have been successful. "Machine design" is an essential part of plant design in the chemical field and there are many generalizations which would have been helpful. Materials of Construction was also a little disappointing and the lengthy report on portland cement seems unnecessary.

Future editions will rectify these faults, which are all relatively minor troubles. Meanwhile here is the first edition. The question for chemical engineers is really, Can I afford to be without this book? My answer is, No! And I should like to extend to Mr. Liddell my congratulations for a piece of work that is—memorable!

CHARLES WADSWORTH.

Recent Chemical & Metallurgical Patents

Production of Cyanamide From Calcium Cyanamide—J. H. Lidholm, of Sweden, had already patented (U. S. Pat. 1,380,223) a process for adding calcium cyanamide to the water simultaneously with the addition of carbon dioxide for precipitating calcium as carbonate. In this way the production of dicyandiamide is avoided. It has since been found, however, that a regulation of the alkalinity must be made to below 0.5 normal and at a temperature of roughly 30 deg. C. By keeping the temperature slightly above 30 deg. C. the precipitation of cyanimide carbonate is avoided. In this way a very nearly theoretically perfect production of cyanamide from calcium cyanamide can be obtained. (1,280,223. Nov. 21, 1922.)

Process for the Production of Hydrogen Sulphide—Henry Howard, assignor to the Grasselli Chemical Co., has invented a process for the production of hydrogen sulphide. It consists essentially in the use of zinc sulphide ores and sulphuric acid, and produces zinc sulphate and hydrogen sulphide. It differs from the so-called Christensen process, in which the same reaction is employed, in the volume of sulphuric acid used and in the fine division of the sulphide ore. Christensen used large volumes of sulphuric acid in order to dissolve the zinc sulphate as it was formed. The author of this process uses a very finely divided zinc sulphide (which passes through 200 mesh) and agitates this in about five volumes of sulphuric acid, although the actual ratio of acid to ore may vary over a considerable range. After the batch has been completed, one-half of the acid may be recovered and used again. (1,435,471. Nov. 14, 1922.)

Manufacture of Vulcanized Rubber Articles—M. H. Harrison and Harold A. Morton, of Akron, Ohio, have assigned to the Miller Rubber Co. the following patent for the manufacture of vulcanized rubber. The objection to present processes for making rubber mixes is that on the calender rolls, which are so geared that they operate at differential speed, considerable heat is generated, and vulcanization either in whole or in part takes place on the rolls themselves. This ruins the batches of rubber. To avoid this the authors suggest making two separate mixes, one of the rubber with zinc oxide and sulphur, the other with the rubber, zinc oxide and the organic accelerator. When these sheets have been rolled to a thickness of 0.015 in., it is possible to pile them up one on top of the other and so vulcanize the pile perfectly. Thus no loss is entailed due to the earlier vulcanization. (1,434,892. Nov. 7, 1922.)

American Patents

Issued Nov. 28, 1922

The following numbers have been selected from the latest available issue of the *Official Gazette* of the United States Patent Office because they appear to have pertinent interest for *Chem. & Met.* readers. They will be studied later by *Chem. & Met.'s* staff, and those which, in our judgment, are most worthy will be published in abstract. It is recognized that we cannot always anticipate our readers' interests, and accordingly this advance list is published for the benefit of those who may not care to await our judgment and synopsis.

1,436,739—Evaporator.
1,436,819—Diolefines.
1,436,820—Manufacture of Paint.
1,436,940—Separation of Chloracetones.
1,436,949—Production of Ammonia.
1,437,041—Nitration of Cellulose.
1,437,045—Manufacture of Motor Fuel.
1,437,101—Recovery of Gasoline.
1,437,102—Recovery of Gasoline.
1,437,191—Elimination of Phosphorus.
1,437,292—Distillation of Carbonaceous Materials.

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Catalyzer and Method of Producing the Same—W. D. Richardson, assignor to Swift & Co., has developed a method of producing a more efficient nickel catalyst by abrading crude nickel in the presence of water. The present method consists of grinding the nickel in the presence of oil to be hydrogenated. By this new process nickel is put into a ball mill in reasonably large lumps, either with or without an abrasive material, and the whole is ground to roughly 200 mesh in the presence of water. Then it becomes necessary to dry the mud thus produced and grind again the nickel catalyst with oil, inasmuch as water is a dilatory substance to the hydrogenation process. The greater efficiency of the nickel produced by water abrasion is given as a reason for adopting the extra processing. (1,419,986. June 20, 1922.)

The Use of Vanadium Oxide as a Catalyst—C. H. McDowell, H. H. Meyers and (in the case of patent 1,420,201) Warren B. Pattison have assigned their patents on the production and use of vanadium oxide as a catalyst to the Armour Fertilizer Works. Patent 1,420,203 has to do with the production of the catalyst. Alumina from the mineral alunite is used as a carrier for the vanadium and, for example in the case of sulphuric acid, can oxidize from 50 to 60 per cent of the sulphur dioxide to sulphur trioxide. In the presence of about one part of vanadium oxide to ten parts of alumina, a conversion of better than 87 per cent is obtained. In preparing the catalyst, ten parts of ammonium vanadate is added to about one hundred parts of alumina from alunite. The mixture is moistened enough to permit molding and briquets of suitable shapes are then prepared with just enough pressure to bind the material together. The heating of the dried briquet must be comparatively slow, but they are very durable if the heating is carried out carefully. Catalysts so prepared may be used as in patent 1,420,201 for the oxidation of ammonia, or as in patent 1,420,202 for the oxidation of sulphur dioxide in the preparation of sulphuric acid. Various temperatures and other conditions necessary to carry out the reactions are described in detail in the patents. (1,420,201; 1,420,202 and 1,420,203. June 20, 1922.)

Preparing Pigment Suspensions—George W. Acheson, of Newark, N. J., has been granted a patent for a process of preparing pigment suspensions in oil to be used in the manufacture of paints, inks, varnishes and similar products, consisting of a pigment and a vehicle. As a typical example of how the invention is carried out the author takes a suitable pigment such as ultramarine, zinc white or carbon black, and deflocculates it according to the known process whereby it is wholly or partly converted into a colloidal condition. The resulting paste is thinned with water to the consistency of a thin cream. This is then poured with stirring into the vehicle, which may, for example, be boiled linseed oil or a hydrocarbon oil of the paraffine type. To the pigment-oil-water mixture or emulsion is then added a small portion of some flocculating electrolyte, such as a solution of alum or dilute hydrochloric acid. After stirring, the mixture is permitted to stand until a curdlike precipitate or deposit is formed. These curds consist chiefly of oil and pigment from which the bulk of the water has been eliminated. Excess water may be drained off or can be evaporated as, for instance, by passing the mass through steam-heated rolls. The resulting product is then ready for shipment. (1,431,079. Assigned to Acheson Corporation of New York. Oct. 3, 1922.)

Acetaldehye From Acetylene—In the synthetic production of acetaldehyde a current of acetylene is passed over the mercuric salt in an acid medium. The activity of the mercuric catalyzer rapidly diminishes and the absorption of the acetylene becomes proportionately lower, finally stopping completely when the mercuric salt is reduced to the state of a grayish powder. The problem then is to regenerate this mercuric salt by oxidation. In the present patent, L. E. M. Trevoux of Petit-Quevilly, France, maintains the activity of the catalyzing agent by adding an oxidizing substance such as ferric oxide. When in turn the oxidizing agent is exhausted, the liquid is decanted and the ferric salt is again generated by boiling with nitric acid

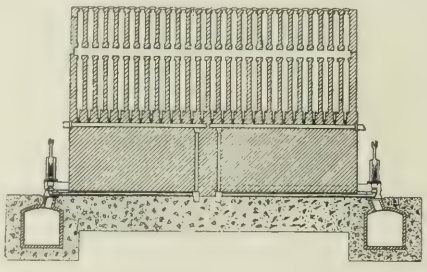
or preferably by electrolysis. It is this electrolytic oxidation that forms the principal feature in the patent. (1,428,668. Assigned to La Société Anonyme de Produits Chimiques Etablissements Maletra, of Petit-Quevilly, France. Sept. 12, 1922.)

Electric Furnace—O. A. Colby, of Irwin, Pa., has patented a crucible furnace, wherein the crucible is built up of alundum, sintered in place, resting on a resistor made of carborundum blocks. Current is led in by massive graphite blocks. Contacts at each end of the carborundum resistor is made by a packing of granular graphite. Through the brickwork surrounding the crucible, and at each end of the resistor, is provided a well or hopper, which is kept packed with this granular graphite, periodically replenishing that which is burned. These essential parts of the furnace are encased in refractory firebrick and insulating material, the whole bound with steel plates and mounted on trunnions. (1,435,211, Nov. 14, 1922. Assigned to Westinghouse E. & M. Co.)

The Solidifying of Sulphur—Present practice in the sulphur field consists of pumping molten sulphur from the pipes as it comes to the surface of the ground into a large area, roughly hundreds of feet square, and from 15 to 20 ft. high. The sulphur solidifies finally into a large mass or block, and it takes sometimes as long as 2 months for the material to solidify completely. Then it must be blasted down, much as rock is blasted, before it can be loaded into cars. The present invention has for its purpose the solidifying of sulphur in such a manner that it can be loaded directly into cars and does not have to be stored over long periods of time. It consists essentially of a belt conveyor, on which the sulphur is run to a definite thickness of layer. This layer solidifies very rapidly, since it is comparatively thin. Another layer is then superimposed immediately upon the solidifying of the first layer, and this process is continued as the belt slowly moves forward. A thickness of cake can be built up to any desired dimensions, depending on the length of the belt, and as the cake comes off the end of the belt, it can be broken up to any desired size for immediate shipment. (1,419,911. Raymond F. and Harold S. Davis of Pittsburgh, assignors to the Texas Gulf Sulphur Co. June 20, 1922.)

Recovery of Oxides of Nitrogen in Sulphuric Acid Manufacture—In the chamber or tower processes for the manufacture of sulphuric acid, oxides of nitrogen are added to sulphur dioxide, and with the addition of steam they produce sulphuric acid. These oxides of nitrogen are later absorbed in a reduced condition in the Gay-Lussac tower by means of a downcoming stream of cold, fairly concentrated sulphuric acid. If a very small quantity of sulphur dioxide, approximately 0.10 per cent, is present, the absorption takes place with greater rapidity than in its absence. This was developed by the author in patent 1,205,723. It was found, however, that the gases which escape from the Gay-Lussac tower could not be absorbed readily in the presence of this small quantity of sulphur dioxide in the ordinary water scrubbers, because the presence of sulphur dioxide prevented the re-oxidation of the oxides of nitrogen to the higher and soluble oxides. In order to obtain as efficient an absorption of oxides of nitrogen in the Gay-Lussac tower, and in addition, to recover all the oxides of nitrogen, the absorption is carried out in the presence of a small quantity of sulphur dioxide, after which the gases emerging from the Gay-Lussac tower are run through milk of lime scrubbers, which removes the sulphur dioxide and permits the subsequent oxidation of the oxides of nitrogen to the higher oxides, which are then removed in ordinary water scrubbers. Several other systems of recovery are possible, and are detailed at some length in the patent, all of them having to do with the fundamental problem of attaining the higher oxides of nitrogen for absorption in water in some way or other. (1,420,477. Andrew M. Fairlie, of Atlanta, Ga. June 20, 1922.)

Coke-Oven Decarbonization—All coke ovens of the vertical flue regenerative type are troubled with more or less carbonization of the fuel gas nozzles. To correct this it is the practice to introduce air into the fuel gas supply pipes at their outward ends during the period when that side of the gas channel is not passing gas to the vertical flues. This air burns and removes part



of the carbon. Due to the serious cooling effect and consequent cracking of brickwork, which a large quantity of this cool air causes, it is not possible to burn off all the carbon in this manner, and resort must be had to punching out the nozzles from the inspection holes above, which is costly and laborious.

In this invention, decarbonizing air is supplied to the inner ends (in the center of the oven). This preheats the air and thus a sufficient quantity can be introduced without danger of cracking the brickwork to decarbonize the nozzles completely. Also, the nozzles which carbonize worst are in the center of the oven and these receive the supply of decarbonizing air first. The accompanying figure shows the general layout of air passages to suit this invention. (1,435,361. Louis Wilputte, assignor of two-third to Alice A. Wilputte. Nov. 14, 1922.)

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Purifying Acetylene — Phosphorus compounds in acetylene are oxidized to phosphorous acid and removed as such by treatment with oxygen, preferably at a raised temperature, in the presence of activated charcoal as catalyst. Acetylene mixed with a small proportion of oxygen or air is passed through a reaction tower packed with activated charcoal and heated to 80 to 100 deg. C.; alternatively, acetylene and air are passed in succession over the charcoal. Phosphorous acid is recovered by extracting the charcoal with hot water. (Br. Pat. 184,184; not yet accepted. Consortium für Elektrochemische Industrie Ges., Munich. Oct. 4, 1922.)

Artificial Silk—To obtain non-tarnished films, artificial threads and other articles capable of taking a dye, from cellulose nitrate, acetate, butyrate and other esters of cellulose, there is added to a solution of the ester in a relatively volatile organic solvent a small quantity of a non-volatile organic solvent soluble in water. After forming the thread or film, by the evaporation of the volatile solvent, the non-volatile solvent is extracted by washing with water. As non-volatile solvent formamide, acetamide, chloral, and chloral hydrate are employed. The volatile solvent may be methyl, ethyl, butyl or amyl formate or acetate, together with methyl or ethyl alcohol. (Br. Pat. 184,197. J. Duclaux, Paris. Oct. 4, 1922.)

Alkali Phosphates—Mineral or precipitated calcium phosphate or bone ash is mixed with a solution of sodium potassium or ammonium sulphate and the product treated with sulphur dioxide. The reaction products are calcium sulphate and a soluble phosphate corresponding to the sulphate used, a soluble sulphite being also formed when tricalcium phosphate is treated. The formation of sulphite can be avoided if one of the three molecules of sulphate required for the reaction is replaced by one of sulphuric acid, and this may be accomplished, in the case of sodium phosphate, by the use of niter cake. No sulphite is formed when precipitated calcium hydrogen phosphate is treated, and in this case the sulphur dioxide can be recovered by heating the filtered reaction liquid. Other acids readily volatile from hot solutions, such as acetic or formic acid, or carbon dioxide, or hydrogen sulphide, may replace sulphur dioxide. (Br. Pat. 184,206. J. G. Williams, West Bridgford, Nottinghamshire. Oct. 4, 1922.)

Sweetening Gasoline — The desulphurization of liquid hydrocarbons, such as kerosene, benzine or shale oil, by treatment with alkaline hypochlorite, such as sodium hypochlorite, with free alkali is preceded, followed or both preceded and followed by treatment with alkali. The treatment may be effected in a vessel in which brine is being electrolyzed for the production of sodium hypochlorite, and the temperature may

be raised to, say, 120 deg. F. The product may be filtered through animal charcoal, fullers earth, dehydrated alumina or other adsorbent substance. (Br. Pat. 184,281. A. E. Dunstan, Sunbury-on-Thames. Oct. 4, 1922.)

Aromatic Amines—Aromatic amines are obtained by heating unsubstituted phenols with a mixture of ammonia, an ammonium salt other than sulphite and an alkali sulphite. The alkali sulphite may be that contained in the crude melt resulting in the preparation of the phenol from the corresponding sulphonic acid by alkali fusion. An example is given of the preparation of beta-naphthylamine. (Br. Pat. 184,284. W. L. Galbraith, W. V. Shannan, W. G. Adam and N. E. Siderfin. London. Oct. 4, 1922.)

Tungsten Filaments—Drawn tungsten filaments are produced from materials in which uranium oxide, or a substance that will yield uranium oxide in the subsequent treatment, is incorporated. The substance may be incorporated with unreduced tungstic oxide or with the reduced tungsten powder. It may be added as a solution of uranium nitrate, which is converted by subsequent heat-treatment into the oxide. Other substances—for example thorium oxide or boric acid or both—may also be present in the tungsten material. The tungsten material described in specification 155,851 may be used. (Br. Pat. 184,291. W. H. Le Maréchal, London. Oct. 4, 1922.)

Synthetic Resins — Synthetic resins obtained by the condensation or polymerization of aldehydes with alkali are rendered stable toward water by treating them in a state of fine subdivision with water, to which a little acid is preferably added. The products are soluble in fatty oil, spirit, benzene and other solvents used in the manufacture of varnishes; by rolling in the soft state they can be converted into the commercial form of sheet shellac. According to the example, the resin resulting from the condensation or polymerization of acetaldehyde is ground in a ball mill with a 3 per cent aqueous solution of acetic acid, the product filtered off and either melted or dissolved in a spirit or oil solvent. (Br. Pat. 184,442; not yet accepted. Consortium für Elektrochemische Industrie Ges., Munich. Oct. , 1922.)

Synopsis of Recent Chemical & Metallurgical Literature

Eliminating Static Electricity

The variety of circumstances under which static electricity is produced is surprising, and causes trouble in many chemical industries. In this connection the Bureau of Standards has prepared for publication, in the journal of the National Association of Dyers and Cleaners, a brief account of the sources of static electricity and some suggested means of avoiding it.

In general appreciable charges of static electricity can be produced only when the surrounding air is very dry, and static troubles almost never occur when the relative humidity is greater than 70 per cent. Consequently, the use of damp atmospheres, obtained, for instance, by injecting steam into the room, is one simple and effective means of combating the evil. Another precaution is to connect all metal parts of machinery together by substantial wires so that no difference in electrical potential can be produced between the various parts.

Fusion Rotary Retort

C. J. Goodwin, speaking before the South Wales Institution of Engineers, described the fusion retort and the principles underlying its design and operation. This device is planned for the recovery of oil from coal shale or like substances, which for effective work in this apparatus must be reduced to fine size in order to increase the oil yield, permit lower retort temperatures and insure more complete utilization of the raw material than is possible if the undersize pieces have to be rejected.

For successful retort operation the thickness of layer in contact with the retort should be a minimum and this material should be turned over frequently while being gradually increased in temperature so that the heated surfaces are free from caked material. The fusion retort accomplishes the stirring by rotation of the retort and use of a loose "star" or "cross" breaker. This breaker rolls in the retort when this is rotated, falling back from one edge to another with a chipping or hammering action that is intended to prevent a caking of the material on the inner shell of the retort. With a six-point star it is claimed that the noise and power consumption are sufficiently low to avoid any difficulty. The general character of the retort is shown in the illustration herewith.

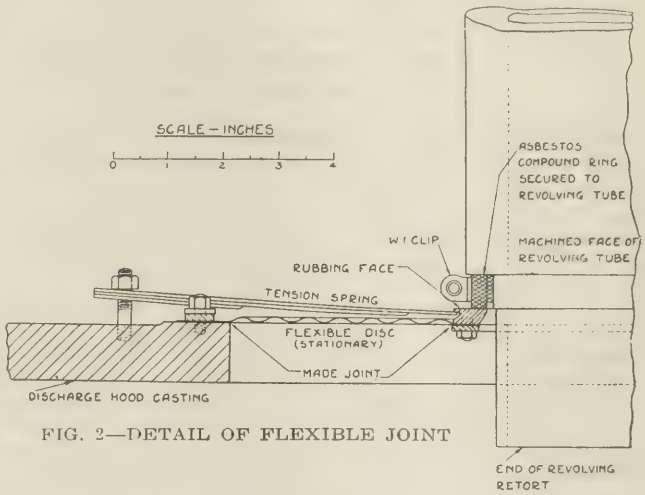


FIG. 2—DETAIL OF FLEXIBLE JOINT

The use of the rotary retort requires a gas-tight flexible joint at the ends. This feature of the construction is one of the most difficult. The form of flexible joint recommended is shown in Fig. 2. It is claimed that this retort has low first cost, low upkeep cost, low power requirement for operation and minimum contact of gas and oil vapor with hot surfaces. By progressive advance of the material through the retort, preliminary eduction of moisture is accomplished and desirable heating up of the solid to be retorted is insured.

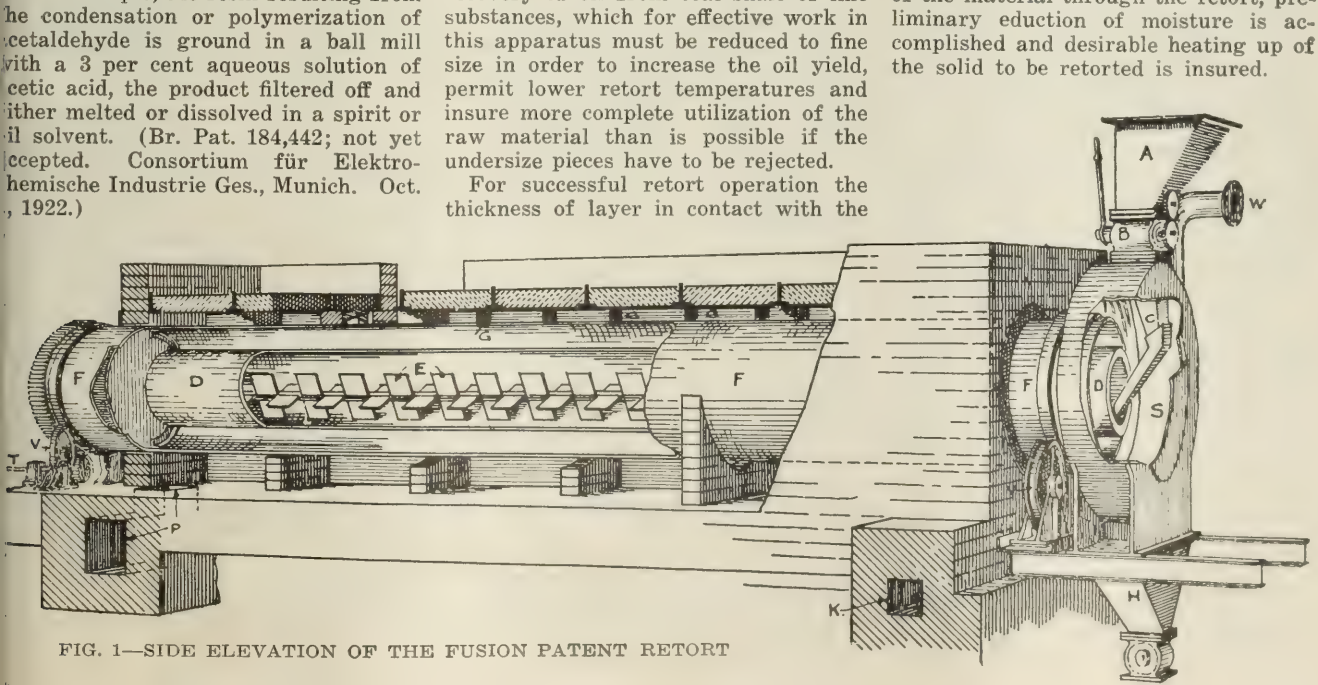

FIG. 1—SIDE ELEVATION OF THE FUSION PATENT RETORT

Interdependence of Economics and Engineering Keynote of A.S.M.E. Convention

Forty-third Annual Convention of American Society of Mechanical Engineers Attracts Two Thousand Members and Guests to New York

THE American Society of Mechanical Engineers gathered in convention at their New York headquarters Dec. 4 to 7 for a 3-day session of marked success, about 2,000 members and guests being registered. Following the usual custom of the society, the first business on the program was the election of officers for the ensuing year, which resulted as follows:

President, John L. Harrington, of Kansas City; vice-presidents, W. H. Kenerson of Brown University, Earl F. Scott of Atlanta, Henry H. Vaughan of Montreal and W. S. Finlay of New York City; managers, A. G. Christie of Johns Hopkins, J. H. Herron of Cleveland and Roy V. Wright of New York; secretary and treasurer, W. H. Wiley of New York.

Engineer Should Lead Nation

At the opening session, Dean Dexter S. Kimball of Cornell, the retiring president, made an address in which he urged that some change be made in our industrial system so that a more equitable distribution of the fruits of industry might be obtained. Otherwise, he feared that our present civilization can not endure. Dean Kimball said that engineers must take a more prominent place in control of national affairs, and closed his speech with the following inspiring words:

"The scientific mind is capable of high development along business and financial lines, while yet retaining in its background the powerful scientific methods of attacking problems which have made modern industry possible. And this is the great contribution that the engineer can bring to the problem of universal well-being. The one great thing we are all seeking is justice; but there is no justice where there is no knowledge, and the engineer, again using this term in its widest sense, alone possesses an accurate and intimate knowledge of industry."

Engineering and Economics

The keynote of the convention was sounded on the evening of Dec. 6 when, in a joint session of the A.S.M.E. and the American Economic Association, plans were laid for a closer co-operation between engineers and economists. The principal speaker at this meeting, Dr. Wesley C. Mitchell, director of the National Bureau of Economic Research, pointed out that both the engineers and economists had much to learn from each other, and that, if the principles of economics could be applied by the practical methods of engineers, the true end of all industry —the improvement of the condition of the human race—would come much nearer to realization than at present.

Other speakers at this meeting included H. R. Seager, president of the American Economic Association; E. F. DuBrul, of the Machine Tool Manufacturers' Association; E. M. Herr, president of the Westinghouse Electric & Manufacturing Co., and Dean Kimball, retiring president of the A.S.M.E. It was brought out in the remarks of all these speakers that a vastly greater amount of education, especially along economic lines, was necessary for all, so that we may understand the underlying reasons for industrial conditions, work together for the improvement of these conditions and obtain greater justice and well-being for all.

Pan-American Development

Calvin W. Rice, secretary of the society, who has just returned from South America, where he attended the Brazilian Centennial Exposition at Rio de Janeiro, declared that through the efforts of the engineering profession a new era is dawning for Pan-America. As the envoy of many of the largest engineering organizations in the United States Mr. Rice participated in the International Engineering Congress at Rio, and, with the support of Secretaries Hughes and Hoover and other leading figures in Pan-American development, made a tour of South and Central America.

In Mr. Rice's address, delivered in the nature of a report to the engineers of the nation, announcement was made of the definite accomplishment of three steps in the movement toward the unity of the Americas:

(1) Action has been taken toward effecting a permanent organization to carry out the plans of the Rio congress, with Verne L. Havens of the McGraw-Hill Co., New York, as secretary.

(2) A standardization bureau, as suggested by Secretary Hoover, will be established in every Pan-American country.

(3) The dream of a transcontinental railway is approaching the stage of reality. A meeting to further this project will be called by the nations of Pan-America. Minor C. Keith of Costa Rica, the only living member of the committee that originally recommended the building of this railway, has been asked to preside.

Technical Sessions

The technical sessions were of great interest and were enthusiastically supported. Among the general topics treated were management, material handling, machine shop practice, refrigeration, education and training for industry, research, fuel engineering, steam power engineering, railroad engineering safety, standardization, ordnance, aeronautics, forest products, the power test code, and the boiler code.

L. P. Breckenridge, of Yale University, presided at a joint session of the fuels division of the society and the Stoker Manufacturers' Association. The fuels division has prepared a set of rules for householders governing use of fuel, management of furnace and the burning of substitutes for anthracite. Economy must be practiced by every consumer, the division warned, if an acute shortage is to be averted.

Helium Hearings Begin Before Public Lands Committee

The Committee on Public Lands on Dec. 5 began hearings on the helium bill. The only witness who has appeared at the time of this writing is R. B. Moore, chief chemist of the Bureau of Mines. At the request of the committee, Dr. Moore is explaining to the committee the full history of helium development. This will be completed before the bill itself is taken up. The committee feels that the subject is of sufficient importance that its members should have a clear picture of all the considerations involved in the whole subject of helium.

The committee is much impressed with the widespread sentiment manifested in many sections of the country for the helium bill. This was supplemented by a formal request from the Federated American Engineering Societies asking that hearings begin at this time. In view of this demonstration of interest among engineers and the public generally, the committee voted to begin the hearings at once.

Government Departments Report Year's Work

Active Development of Mineral Wealth Described in Bureau of Mines Report

A SUBSTANTIAL beginning of the active development of that vast mineral wealth which has heretofore been locked up in the public domain of various Western states, but which is now to be liberated under the terms of the general leasing law, has been made, according to H. Foster Bain, director of the Bureau of Mines, in his annual report just submitted to the Secretary of the Interior. In the fiscal year ended June 30, 1922, there was produced from government lands other than Indian lands, 18,236,362 bbl. of petroleum, of which the federal government received as royalty 3,616,852 bbl. worth $4,768,397.61, not including bonuses. In addition, at the end of the year $14,000 a month was being received by the government from natural gas leases on public lands in Wyoming. In the Rocky Mountain field alone there were on government land 336 oil wells, of which 267 were in the Salt Creek, Wyo., field. A hundred other wells were being drilled.

Up to the end of the year there had been issued 294 oil and gas leases in 4 states and 7,727 prospecting permits, on each of which drilling is required, in 18 states and Alaska. These figures do not include operations within the naval petroleum reserves, which by executive order are now administered by the Bureau of Mines. The field work is directed through a supervisor who has headquarters at Denver with branch offices at Casper and Salt Creek in Wyoming, Bakersfield, Taft and Maricopa in California, Winnett, Mont., and Shreveport, La.

Survey of Government Oil Wells

The largest number of producing wells belonging to the government is in the Salt Creek field of Wyoming, where the government holds title to nearly all the land. During the year the producing capacity of the wells far outran the capacity of existing pipe lines.

In California the principal activity has been with regard to leases within the naval petroleum reserves. The year marked final adjudication of the most important outstanding contest as to oil lands, that of the Honolulu Consolidated Co. Leases were granted by the Secretary of the Interior and accepted by the company and a drilling campaign promptly arranged. A careful study made by the Bureau of Mines brought out the fact that up to March 4, 1922, the government lands had lost by drainage approximately 22,000,000 bbl. of oil through failure to drill offset wells. Of this, on the scale now in effect, the government's loss in royalty may be estimated at 6,800,000 bbl., equivalent to $8,800,000. To prevent further losses, leases were accordingly granted to such lands as were being

(Continued on page 1192)

Fries Commends Personnel in Report of Chemical Warfare Service

THE WORK of the Chemical Warfare Service during the last fiscal year is reviewed in detail by General Fries in his annual report. The report itself covers thirty-nine pages. General Fries emphasized as the predominant impression the loyal and efficient manner in which the personnel have performed their duties under the stress of emergency work and the ever-present uncertainty as regards the continuance of the Chemical Warfare Service.

"This latter situation is a matter of real importance," says the report. "With the action of the Limitation of Armaments Conference, followed later by evident indications that the appropriation for this service would be very much curtailed, a large proportion of the civilian personnel has been confronted with the problem of seeking employment elsewhere at some indefinite future date.

"The organization has been built up carefully, and this has resulted in personnel of much training and valuable experience severing their previous connections and becoming definitely identified with this work. That these uncertain conditions did not effect the morale of the organization greatly is due to the high character and real interest of these people in their work. It cannot be urged too strongly that efforts be made to have definite policies established regarding the activities to be carried on by the Chemical Warfare Service. The personnel must know where it stands.

Service a Necessity

"The close of another fiscal year, with its attendant experiences and knowledge gained, leaves a keener and more definite realization of the importance and necessity for chemical preparedness. In any consideration of policies pertaining to the national defense, the field of chemistry dare not be neglected. Certainly investigations into the possibilities of chemical warfare must be continued and as information is obtained it must be made available to the army and navy and incorporated in plans and training.

Efforts of Past Year

"The year ended June 30, 1922, was noteworthy in many respects as regards chemical warfare. One of the outstanding features was the growing appreciation of the range covered by chemical warfare, and its usefulness in peace as well as in war. The rôle which chemical warfare must play in defense alone is a vast one and entitles it to the serious consideration of every student of defense.

"The use of smoke and incendiary materials for the purpose of screening

(Continued on page 1192)

C. W. S. Appropriation Cut

The Director of the Budget has approved an appropriation of $482,240 for the Chemical Warfare Service for the next fiscal year. This is a reduction of $135,000, the amount appropriated for the current fiscal year.

Will Attempt to Have Budget Enlarged

Cut in Budget Affects Salaries of Chemical Engineers

During this fiscal year the Chemical Warfare Service is expending $600,000 for the purchase, manufacture and test of chemical warfare gases or other toxic substances, for gas masks and other offensive and defensive materials and appliances. Out of that amount the service is expected to pay for all necessary investigations, experiments and research work. The purchase of chemicals and all scientific and technical apparatus and instruments must be taken from the same appropriation. It also is to include the miscellaneous operating expenses and the salaries of personnel.

A large portion of the decrease, upon which the Director of the Budget insisted, is being made in the salaries of the higher grade members of the staff. For instance, during the last fiscal year six chemical engineers of the $4,500 grade were allowed. This was reduced to three during the current fiscal year. During the next fiscal year no engineers of that grade are to be employed. The four associate chemical engineers of the $3,600 grade, which were allowed during the last fiscal year, are not provided for in the new budget. The highest salary allowed a chemical engineer is $2,800 and only one of that grade is provided.

At the sacrifice of a number of subordinate chemical positions, the number of principal chemists of the $6,000 grade has been increased from four to nine. During the current fiscal year six assistant chemists were provided. The Director of the Budget has approved an additional assistant chemist of the $2,500 grade for the next fiscal year. The new budget makes provision for one mechanical engineer at $3,600. The safety engineer formerly employed is dropped, as are the chemical laboratorians, the pathologists, the physiologists, the technical adviser, the technical patent expert, the associate and assistant technologists, and the toxicologists.

The friends of the Chemical Warfare Service in Congress will make a determined effort to override the Director of the Budget in the matter of Chemical Warfare Service appropriations. There is reason to believe that Congress will be convinced that the appropriation allowed by the Budget Bureau is inadequate and that an increase will be carried in the appropriation bill.

Equipment Association Begins Work

Opens National Offices in New York City and Launches Important Activities

The Chemical Equipment Association, comprising manufacturers of equipment essential to the chemically controlled industries has established national executive offices at 1328 Broadway, New York City. It has begun active work through a national membership for the fostering of trade in chemical equipment; for the improvement of practices in the production and distribution of such equipment, and in the performing of engineering services incidental thereto.

Not only does the activity of this association signalize the adoption of trade association methods by the chemical equipment companies, but it represents a movement toward manufacturing and distributing co-operation along the lines recommended by Secretary of Commerce Hoover, who personally encouraged the organization of the association. Commenting on the growing tendency toward co-operative associations, the New York *Tribune* in its issue of Nov. 5 quoted an officer of the Chamber of Commerce of the United States as follows:

> Such supply company organizations as the Railway Equipment Association, the Motor and Accessory Manufacturers Association, the Association of Ice Cream Supply Men, the recently formed Chemical Equipment Association and other groups representing the supply and equipment ends of leading industries, the members of which are manufacturers of miscellaneous commodities, but connected with a specific industry; for market expansion, educational work, publicity, research, credit protection and prevention of trade abuses is one of the most interesting current trade association trends.

The Chemical Equipment Association was organized Sept. 12, 1922, following preliminary activities of an organization committee of representatives of leading manufacturers.

The officers of the association are: President, Pierce D. Schenck, president of the Duriron Co., Inc., Dayton, Ohio; vice-presidents, J. George Lehman, vice-president and general manager of the Bethlehem Foundry & Machine Co., Bethlehem, Pa.; Walter E. Lummus, president, the Walter E. Lummus Co., Boston, Mass.; Adolph Coors, Jr., vice-president, Coors Porcelain Co., Golden, Colo.; treasurer, Percy C. Kingsbury, chief engineer, General Ceramics Co., New York City; secretary, Robert Everett.

The directors are: H. N. Spicer, the Dorr Co., New York City; P. S. Barnes, the Pfaudler Co., New York City; Edwin C. Alford, T. Shriver & Co., Harrison, N. J.; T. C. Oliver, Chemical Construction Co., New York City; Hamilton Allport, E. B. Badger & Sons Co., New York City.

The association has already established communication with nearly two hundred of the large industrial associations of the country, announcing itself as a source of information in chemical equipment supply matters, and has begun a regular bulletin service.

New York Section, A.C.S., Elects Officers

The separation of isotopes and their properties was the subject of a talk by James Kendall of Columbia University before the New York section of the American Chemical Society at Rumford Hall, Dec. 8. The subject was very timely in view of the recent selection of Frederick Aston as recipient of the Nobel prize in chemistry, in recognition of his work on this subject.

At the short business meeting which preceded Professor Kendall's talk, officers for 1923 were elected as follows: Chairman, Dr. C. A. Browne, N. Y. Sugar Trade Laboratory; vice-chairman, C. E. Davis, National Biscuit Co.; secretary-treasurer, Benjamin T. Brooks, Mathieson Alkali Works.

Executive Committee: M. H. Ittner, chief chemist, Colgate & Co.; James Kendall, Columbia University; H. C. Parmelee, editor, *Chem. & Met.*, and H. G. Sidebottom, Jayne & Sidebottom, Inc.

Councilors: C. A. Brown, C. E. Davis, Benjamin T. Brooks, James Kendall, H. C. Parmelee, H. G. Sidebottom, R. G. Wright, F. H. Getman, Ellwood Hendrick, K. G. McKenzie, David Wesson, H. R. Moody, M. H. Ittner, A. C. Langmuir, D. W. Jayne, B. R. Tunison, A. W. Thomas, Williams Haynes, Lois M. Woodford, Mary E. Pennington and F. M. Turner.

Chemical Exports Steady

Three Million Total for Month — Increase in Fertilizer Business

Exports of chemicals and allied products during October were valued at $8,159,044, according to returns to the Bureau of Foreign and Domestic Commerce. This figure indicates the continuance of exports in practically the same volume as in September and in October of 1921.

During October there was a slight increase in the value of the exports of chemicals proper, as compared with September. The value of chemicals, apart from allied products, exported in October is given as $3,811,342. There was a decided increase in the volume of fertilizers and fertilizer materials exported, but the value of those exports was less in October than in September. Fertilizers to the extent of 69,509 tons were exported during October, as compared with 55,518 tons in September. Exports of sulphate of ammonia decreased from 9,332 tons in September to 6,436 tons in October. Practically all of the October exports of this material went to Japan. Explosives exports in October aggregated 1,233,772 lb., a slight decrease as compared with the September forwardings.

Among the more significant items making up the October export figures are the following:

Benzol (lb.)	2,917,749
Sulphuric acid (lb.)	482,036
Boracic acid (lb.)	120,983
Wood and denatured alcohol (gal.)	124,718
Acetate of lime (lb.)	1,768,630
Calcium carbide (lb.)	720,272
Borax (lb.)	913,726
Caustic soda (lb.)	8,605,123

American Petroleum Institute Meets

Third Annual Convention, in St. Louis Attracts Good Attendance

The American Petroleum Institute held its third annual meeting in St Louis, Dec. 6 and 7. Addresses by men of national prominence in the petroleum industry attracted a large attendance at the various meetings of the Institute.

Two topics of vital importance to the industry were brought to the attention of those attending the meeting: first the methods of producing, to the best possible advantage, commercial gasoline, and second, the standardization of oil-drilling methods and equipment. The latter movement has been launched in order to make it possible to secure repairs and new equipment by reducing the number of varieties of equipment manufactured.

Thomas A. O'Donnell, of Los Angeles, president of the association, assailed centralized government and federal control of industries at the opening general meeting. He said:

"I do not believe in bureaucracy in government. I believe it is destructive and not in the public interest. I believe everybody in the petroleum industry must recognize the danger confronting not only that industry but other lines of effort. The most destructive thing conceivable is an active government interference in business."

Addresses were delivered by Ivy L. Lee, W. S. Farish, of Houston, Tex., president of the Humble Oil & Refining Co.; P. E. Kistler, of Chicago, Ill., president of the Producers & Refiners Corporation, and James J. McGraw, of Tulsa, Okla., vice-president of the Exchange National Bank of Tulsa.

Directors Elected

The following directors were elected:

Pacific Coast Group—P. H. Hillman, Standard Oil Co. of California; K. R. Kingsbury, Standard Oil of California; H. R. Gallagher, Shell Co. of California.

Central United States Group—W. S. Farish, Humble Oil & Refining Co.; Robert W. Stewart, Standard Oil Co. of Indiana; P. C. Crenshaw, Home Oil Co.

Eastern United States Group—George W. Crawford, Ohio Fuel Supply Co.; A. C. Woodman, Union Petroleum Co.; R. D. Benson, Tidewater Oil Co.; Edward Prizer, Vacuum Oil Co.

Ships—J. Howard Pew, Sun Co.

Pipe Lines—J. H. O'Neil, Prairie Pipe Line Co.; A. A. Moody, Jarecki Manufacturing Co.

Europe—W. C. Teagle, Standard Oil of New Jersey.

To fill the unexpired term of office of Judge Martin Carey, deceased, H. L. Pratt, Standard Oil Co. of New York, to represent the Far East section of the foreign trade group.

The principal speakers at the annual banquet, Thursday evening, were Amos L. Beaty, of the Texas Co., and Sir Auckland Geddes, ambassador to the United States from Great Britain.

Appropriations Announced for Government Bureaus

Technical Departments Assigned Budgets to Continue Present Lines of Investigation

Appropriations totaling $1,339,031 for the Bureau of Chemistry in the Department of Agriculture have been approved by the Director of the Budget. The principal items making up this total follow: For carrying into effect the provisions of the food and drug act, $704,401; for salaries and wages, $308,970; for conducting investigations, relating to the application of chemistry to agriculture, $97,900; for collaboration with other departments desiring chemical assistance, $14,000; for the investigation of problems connected with the manufacture of sugar and sirup, $35,000; to carry into effect the provisions of the act with regard to the prevention of imports of impure tea, $38,000; naval stores investigation, $10,000; insecticides investigation, $20,000; for investigations looking to the prevention of grain dust explosions, $25,000; for the investigation and development of methods of utilizing wool-scouring waste, $9,000.

Personnel

The budget for the next fiscal year provides for the employment of 219 chemists in the bureau. There are in addition a considerable number of employees with chemical training who are classified under other titles.

The budget calls for an appropriation of $310,775 for the Bureau of Soils. The principal items making up that total are: Salaries, $76,440; for chemical investigations of soil composition and soil minerals, $23,110; for physical investigations of important properties of soil, $12,225; for investigations of fertilizers, $60,000; for soil surveys, $120,000.

Bureau of Standards

Total appropriations of $1,742,360 were approved for the Bureau of Standards. The principal items making up that total are as follows: Salaries, $432,360; for apparatus, machinery and other appliances, $75,000; for testing structural materials, $195,000; for maintenance and operation of testing machines, $35,000; for investigation of fire-resisting properties of building materials, $25,000; for investigation of the standards of practice and methods of measurements of public utilities, $95,000; for testing miscellaneous materials, including chemicals, varnishes and inks, $40,000; for the investigation and standardization of methods and instruments employed in radio communication, $40,000; to develop color standards, $10,000; to study technical processes used in the manufacture of clay products, $30,000; to develop methods of standardizing mechanical appliances, $40,000; for the investigation of the problems involved in the production of optical glass, $20,000; to investigate textiles, paper, leather and rubber, to develop standards of quality, $25,000; for the standardization and design of sugar testing apparatus and the development of technical specifications for the various grades of sugar, $40,000; for the standardization and testing of standard gages and screw-threads, $40,000; for investigating mine scales, $15,000; for metallurgical research, $50,000; for investigations of high-temperature measurements and control, $10,000; for the investigation of the principles of sound, $5,000; for industrial research, $190,000; for testing large scales, $40,000; for investigations in the establishment of standards for instruments, tools, electrical and mechanical devices, $100,000; for the purchase, preparation and analysis of standard materials, to be used in checking chemical analyses, $10,000; for the investigation of radioactive substances, $10,000; for the maintenance and equipment of automotive engine test plants, $40,000; for determining fundamental data, $20,000.

Coal-Tar Tariff Provisions Discussed

Department of Commerce Will Compile Monthly Statistics on Imports of Dyes and Chemicals

Applications of the provisions of the new tariff law to imports of coal-tar products were discussed with the customs service by dye importers at meetings last week. Particular interest was evidenced in the attitude to be taken by the customs service in determining whether similar competitive articles are produced in the United States for the purpose of imposing the ad valorem rate based on the United States value.

Work on the rules to govern the imposition of tariff rates on coal-tar products, it was said, is going forward steadily, but progress is necessarily slow because of the scope of the investigations to determine United States value and the substantial results accomplished by imported coal-tar products as compared with domestic products.

To Compile Monthly Statistics

Statistics giving itemized imports of coal-tar dyes and chemicals will be published monthly by the Department of Commerce, through co-operation of the Customs Division of the Treasury Department and the Tariff Commission. Plans are being made to issue the first report in January, if arrangements can be completed in time.

The data will be gathered from customs invoices at New York, the principal port of such entries, by a clerk assigned to this duty by the Tariff Commission, and sent to the commission's headquarters in Washington, where they will be compiled by experts of the chemical division, and sent to the Commerce Department for publication. Colors, strength and, wherever possible, prices will be included in the reports.

It is expected that the monthly reports will be available for publication 2 weeks after the close of each period.

Will Survey White Arsenic Situation

De Long Arranges Conference With Producers, Independent of Investigation Demands of Legislators

The production of a larger supply of calcium arsenate, with which to check the ravages of the cotton boll weevil next season, is the purpose of a conference of manufacturers of white arsenic and calcium arsenate and officials of the departments of Agriculture, Interior and Commerce, to be held at the Hotel Astor, New York, Dec. 13.

The conference was arranged by C. R. De Long, formerly chief of the chemical division of the Department of Commerce and now head of the dye and chemical section of the Tariff Commission. Mr. De Long, who will preside at the meeting, explains that the object will be to find out just how much white arsenic is available for the manufacture of calcium arsenate, the principal boll weevil insecticide.

The Department of Justice will assign an agent to investigate whether there exists an unlawful combination to control the supply and price of white arsenic, according to a letter received by Senator Harris of Georgia from the department. Investigation was asked by Senator Harris after complaints from constituents that the price of calcium arsenate had doubled within a year and that the supply was short.

The Department of Justice also proposes to conduct another investigation into the fertilizer situation, following complaints from some sections that prices are uniform, according to another letter from the department. A fertilizer investigation by agents of the department last spring failed to disclose any combination.

Scarcity Due to Smelters' Inactivity

The high price of the arsenate, which has resulted in Congressional action, is caused, Mr. De Long states, by the shortage of white arsenic. This, he said, is a result of inactivity in the lead and copper smelting industry. The enormously increased demand for the insect poison, together with the decreased supply, has resulted in the present acute shortage, which promises to become more serious unless steps are taken to increase the output. It is hoped, as a result of the meeting, to uncover stocks of arsenic, and make them available for insecticide manufacture and to encourage a new undeveloped output.

Senator Smith of South Carolina introduced a resolution, which has since been adopted, directing the departments of Agriculture and Interior to make an investigation of this industry and report to the Senate the cause of the prevalent high price. It especially directs an investigation of the charges that this product is in the hands of a monopoly. Mr. De Long declares that plans for this conference were made prior to the introduction of the Senate resolution.

Bureau of Mines Report

(Continued from page 1189)

drained, and offset wells have been drilled with remarkable speed.

Other Mineral Reserves

The United States Government is one of the largest coal-land owners in the world and also holds important reserves of phosphate, potash and other salts. Although just at present, because of the prior development of mines and industries in the Eastern states, coal mining on the public domain is overshadowed by private industry, in the years ahead the leased mines may well become the more important. Every effort is accordingly being made to establish the new system on a correct basis, properly to protect the public interest in safe and efficient mining, and not unduly to hamper private initiative in operation. Coal is now being mined under lease in Washington, Montana, North Dakota, South Dakota, Wyoming, Utah, Colorado, New Mexico and Nevada. Phosphate rock is being mined in Idaho, and coal and other mines on Indian lands are being supervised in still other states. On the public lands proper the Bureau of Mines is now charged with supervision of 29 coal leases, 200 coal-prospecting permits, 5 coal licenses, 1 phosphate lease, 1 oil-sand lease, 1 potash lease and several potash prospecting permits. In all, nearly 240,000 acres scattered through 10 states require supervision, and the average is rapidly increasing. The work is directed through a mining supervisor with headquarters at Denver, Colo.

Safety and Rescue Work

In addition to the technical supervision of mineral production on public lands, the Bureau of Mines engaged in numerous other activities associated with problems of safety and efficiency in the various mineral industries. During the year, 16,291 persons were trained in first-aid and rescue work, thus constituting a considerable addition to the legion of skilled men and women who stand ready to render valuable humanitarian aid to those subjected to peril in times of mine disasters. Studies of health hazards in the petroleum industry were made by the bureau in co-operation with the Public Health Service and the American Petroleum Institute. Smoke abatement surveys were made at Salt Lake City, Buffalo, N. Y., and Grafton, W. Va. A fuel-economy survey of the government heat and power plants in the District of Columbia was undertaken. New plans were justified and set for impurity allowances in the Salt Creek, Wyo., oil field which will increase government revenue $40,000 per annum on present production. The value of waste coal in dumps at Wilkeson, Wash., was demonstrated, with the result that a plant for the recovery of 150,000 tons is now being erected. The difficulty in the way of using low-priced cyanide in metallurgical work was discovered and remedied, resulting in the breaking of a monopoly in this important chemical material.

Fries Commends C.W.S.

(Continued from page 1189)

troops on the field of battle, for screening naval squadrons at sea in attack or defense, is a field which requires the study of every student of tactics or strategy. Screening smoke materials are applicable to use in every character of projectile, whether dropped from airplanes, fired from guns or thrown by hand. They are used to form the screen for attack, and the screen for defense. The ability to use this screen close to or at a considerable distance from moving troops increases enormously the difficulty of knowing where to aim artillery and other long range guns. Research and development in this line are in their infancy, while the study of the tactical use of smoke has scarcely begun.

"Purely incendiary materials are generally of much less importance. They have their fields of usefulness in attacking military stores, ordnance depots and the like. On the other hand, a smoke-producing material as white phosphorus, which is also capable of creating casualties by burning, has a very considerable importance in attack or defense. White phosphorus is adaptable to use by every arm of the service and every projectile, not only as a smoke as stated above, but as a burning material to attack personnel. While few deaths will result, many will be put out of action, while the moral effect of burning phosphorus is too great to be overlooked at any time.

"Consideration of the possibilities in the field of chemical research will give an understanding of the advisability of continuing the work into the toxicological properties and characteristics of chemical compounds, which information this country must have to even approximate chemical preparedness. It is work that cannot be done properly along scientific lines in any other place than in such an institution as exists in Edgewood Arsenal. In addition, indications are sufficiently clear to show the possibilities of using many of the results obtained in this work to the advantage of the country in peace time. An analysis of the importance of this work in connection with the funds required to carry it on shows clearly a full justification.

Recommendations for Future

"For the healthy and reasonable continuance of the activities at Edgewood Arsenal in future, the following recommendations are made:

Establish a continuity of policy as regards the character and scope of research and development. An absolute minimum of $2,000,000 should be devoted to this work annually.

Increase the activities of the Chemical Warfare School to include the training of selected officers and non-commissioned officers of the line.

Maintain present large-scale plants in an operating condition. This can be done and provide for minor improvements at a cost not to exceed $150,000 per year.

Manufacture a limited number of gas masks and other protective devices annually. A minimum expenditure for this purpose would be $500,000.

Provide for the manufacture of training supplies and munitions at an estimated minimum cost of $200,000 per annum.

Provide for the upkeep and operation of utilities and the preservation of supplies and munitions in storage. This is an expenditure of approximately $400,000 per year.

Revoke the decision to turn over a section of the arsenal and a part of its facilities as an artillery station. All space and facilities are required for the normal peace time operation of the activities concentrated at Edgewood Arsenal and at the same time provide for a reasonable expansion in case of an emergency.

"The past year has seen the establishment of a sound and reciprocal basis of relations between the Chemical Warfare Service and other branches of the War and Navy Departments, and also other departments of the government. Chemical warfare can aid these departments greatly in peace. The store of knowledge in the C.W.S. of poisonous compounds has been shown to be of the greatest value to almost every branch of the government."

Personal

George W. Heintz, for a number of years vice-president and general manager of the United States Smelting, Refining & Mining Co.'s metal operations in Utah, Colorado, Nevada, Arizona and California, with headquarters at Salt Lake City, and for the past 3 years a vice-president in charge of Western operations of the same company in Boston, has resigned, effective Jan. 1, 1923. Simultaneously Mr. Heintz relinquishes the executive office of the Sunnyside Mining & Milling Co., the Bullion Beck Mining Co., the Niagara Mining Co. and the United States Stores Co., all of which are subsidiary or affiliated companies of the United States Smelting, Refining & Mining Co. After a short vacation Mr. Heintz will engage in consulting work in Boston.

Chester A. Hammill, geologist, gave an interesting address on recent developments in the oil and gas fields of Texas, at a recent meeting of the Technical Club, Dallas, Tex.

Hugh M. Henton, who is now assistant professor of mining and metallurgy in the Washington State College of Washington, Pullman, Wash., has not been connected with the Aluminum Castings Co., as mentioned in the personal in our issue for Nov. 15.

Dr. Horace C. Porter, consulting chemical engineer on fuels, Philadelphia, Pa., spoke before the Syracuse Section of the American Chemical Society, Dec. 8, on "Coal Carbonization and the World's Fuels."

Marcus A. Grossmann has been appointed metallurgist of the Atlas Steel Corporation, a consolidation of the Electric Alloy Steel Co. and the Atlas Crucible Steel Co. His new headquarters are in Dunkirk, N. Y.

G. A. Swain, assistant to the manager of the supply department of the Westinghouse Electric & Manufacturing Co., has been elected chairman of the committee on instruments and measurements of the American Institute of Electrical Engineers.

Market Conditions

In Chemical, Metallurgical and Allied Industries

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities
Prevailing Prices and Market Letters From Principal Industrial Centers

New Records of Industrial Activity

Production and Distribution Movements of Basic Commodities Show Striking Increases, Thus Confirming Other Evidence of Business Expansion

OCTOBER set records for even greater industrial activity than in any month of the current year. The output of almost all basic commodities showed large increases, sometimes even when the usual seasonal declines were expected. Among others, the following products were produced in larger volume than in any month since 1920: pig iron, steel ingots, byproduct coke, copper, zinc, wood chemicals, cement, brick and crude petroleum. Consumption of cotton, wool and newsprint paper were at new high levels.

Corresponding increases are shown in the activity of all distributive movements, such as wholesale and retail trade, car loadings, bank clearings, magazine and newspaper advertising, postal receipts and the greater demands for money.

TABLE I—MONTHLY PRODUCTION OF BASIC COMMODITIES IN TERMS OF AN ESTIMATED NORMAL

(Estimated normal production = 100 per cent)

Commodity	May	June	July	Aug.	Sept.	Oct.

Textiles Active

The textile industries, which are probably the most important consumers of chemical products, reported figures to the Department of Commerce showing the largest consumption of cotton and silk for any month in over 2 years. There was also a pronounced increase in the consumption of wool by textile mills in October. The total of 59,282,000 lb. is the largest since 1920, with the exception of March of this year, when 60,368,000 lb. was consumed. Consumption in the first 10 months of this year is about 25 per cent greater than in the corresponding months of last year. Woolen and worsted machinery showed further increases in activity in October. This was particularly marked in spindles and in wide and narrow looms, while combs, due to overtime work, showed 106.4 per cent of hours active in October. Cotton machinery activity also increased. Exports of cotton cloth declined slightly in October, with a total of 50,985,000 sq.yd. Consumption of cotton fabric by tire manufacturers increased.

Metals

Production of pig iron during October totaled 2,638,000 tons, the largest output since December, 1920. Daily blast-furnace capacity in operation increased from 77,005 tons at the outset of the month to 87,935 at the close. Steel ingot production was 3,283,000 tons, as compared with 2,713,000 tons during September, an increase of 21 per cent. Unfilled orders for finished products on the books of the United States Steel Corporation Oct. 31 amounted to 6,902,000 tons, as compared with 6,692,000 tons Sept. 30, an increase of 3 per cent.

The production of both copper and zinc showed large increases in October and in each case exceeds the output for any month in more than 2 years. Stocks of zinc again declined, reaching the lowest figure since 1919.

The petroleum industry established several new records in October. Pro-

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	161.72
Last week	160.60
December, 1921	145
December, 1920	245
April, 1918 (high)	286
April, 1921 (low)	140

The chemical market continued to show the strength that has been evident for the past few weeks. The prices of all of the commodities represented by this index were maintained at the higher levels previously reported. Increases were recorded for glycerine and cottonseed oil.

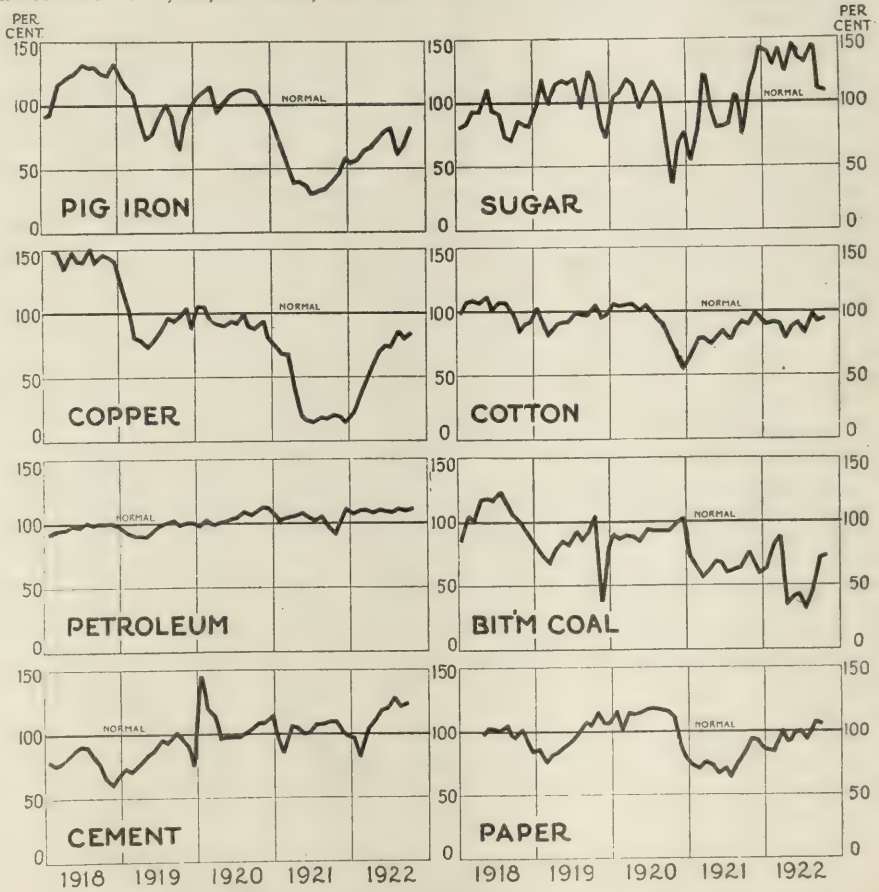

FIG. 1—TREND OF CURRENT PRODUCTION IN CERTAIN BASIC INDUSTRIES

duction at 47,255,000 bbl. of crude is the largest ever reported for one month. Consumption jumped to 52,269,000 bbl., compared with the previous maximum of 50,141,000 bbl. reported for August this year. Stocks again increased to a new high level of 274,438,000 bbl.

Paper and Rubber

Newsprint production also increased in October, with a total of 130,682 tons, or over 5,000 tons more than in September, and, with the exception of August, is the largest for any month since 1920. Newsprint consumption by publishers for October increased to 192,431 tons, or 20,000 tons more than in September, and the largest for any month since these reports were started. Stocks of newsprint, particularly those in the hands of publishers, declined.

Rubber consumption by tire manufacturers increased in October, compared with September, and was about 60 per cent greater than in October a year ago. There was a corresponding increase in the production of tires and tubes. Shipments of tires and tubes showed little change from September, while stocks increased slightly, although still considerably below those reported a few months ago.

Production Trends

Included with this article are two tables of interest as showing the general trend of production in the basic industries. Table I, a compilation of the Federal Reserve Bank of New York, shows production for the past 6 months expressed as percentages of an estimated normal production. In these estimates allowance has been made for year-to-year growth and for seasonal variations. These data are presented graphically in Fig. 1.

Table II is a tabulation of production figures for a number of important chemical and allied industries. These data are taken from "The Trend of Business Movements" section of the *Survey of Current Business.*

Better Demand and Firmer Prices in Chicago

Numerous Advances Reported Principally for Wood-Distillation Products and Heavy Chemicals

CHICAGO, Dec. 8, 1922.

Although little change was apparent in the general condition of the heavy chemical market during the week ended Dec. 7, prices as a whole were very firm and quite a few advances were reported. All wood products were in an exceptionally firm position and still higher prices were predicted in some quarters.

Alkalis Show Better Movement

Caustic soda continued firm, with a good inquiry reported by the dealers. Spot 76 per cent material was quoted in ton lots at $3.50 per 100 lb. for the solid and $4.25 for the ground or flake. *Caustic potash* was in fair demand and imported material testing 88-92 per cent was available at 7¼@7½c. per lb. *Soda ash* moved in a good volume, with $2.25 per 100 lb. the prevailing quotation quotation for 58 per cent material in cooperage.

Alums were in fair demand with the supply light. *Potash alum* was offered in small lots at 4½@5c. per lb. for the lump and 5½@6c. for the powder. *Aluminum sulphate* was scarce and the ground iron-free was very firm at 2½@3c. per lb. *Sal ammoniac* enjoyed a fair demand and the white granular was quoted at 7½@8c., per lb. in small or moderate lots. *Ammonium carbonate* was scarce on spot and the lump was held at 11@12c. per lb. Barium compounds continued firm and were unchanged in price. *Barium chloride* was available at $110 per ton and the carbonate at $90. *Copper sulphate* was in fair demand and crystals were quoted by first hands at 6c. per lb. *Carbon bisulphide* was still scarce and the small supplies on spot were firmly held at 7½c. per lb. *Carbon tetrachloride* was in good demand and the price was advanced to 10½c. per lb. for the large drums. *Furfural* was reported to be moving in a fair way and the price was unchanged at 25c. per lb. for 1,000-lb. lots. *Formaldehyde* was again advanced, the new level being 16c. per lb. in barrels for less than 5-bbl. lots. *Glycerine* was reported to be in a somewhat firmer position and the price of 18½c. per lb. for c.p. material in drums was maintained. *Magnesium metal* was in poor demand and the *powder* was offered in 100-lb. lots at $1.15 per lb.

Linseed Oil and Turpentine Sluggish

Bichromates were unchanged in price and were reported to be moving in a fair way. The *soda bichromate* was quoted at 9@9½ c. per lb. and the *potash* at 12@13c. *Potassium cyanide* was slightly lower due to fresh arrivals and single-case lots were available at 53c. per lb. *Potassium ferrocyanide* was very firm with only small lots available at 42@43c. per lb. *Potassium ferricyanide* was still very scarce, with only an odd lot here and there available at 95c@$1 per lb. *Permanganate of potash* was in fair request and supplies of the imported U.S.P. crystals were quoted at 18@19c. per lb. *Chlorate of potash* was firm with small lots of the powdered offered at 9c. per lb. *Sodium acetate* was in good demand and very scarce with only a few small lots available at 9@9½c. per lb.

Very little demand existed for *linseed oil*, with nearly all factors reporting the market extremely quiet. The boiled oil was quoted today at 90c. per gal. in single-drum lots and the raw at 88c.

Turpentine was in a position similar to that of linseed oil and very little was moved to the dealers. The consuming trade looks for lower prices and shows little or no interest in the present market. Today's price for single-drum lots was $1.46 per gal. delivered to the buyer's plant.

Stronger Market for Steel Products

Slight Declines, However, Shown for Pig Iron and Coke

PITTSBURGH, Dec. 8, 1922.

While there has been expectation in recent weeks in many quarters that steel prices would decline shortly, the expectation should have been confined to bars, shapes and plates, for other finished steel products are in a particularly strong position. Even in the lines mentioned, however, there is no particular weakness seen to be developing. The argument that actual ultimate consumption is hardly equal to the present rate of shipping by steel mills is more easily defended than would be a claim that all the steel now being shipped is passing promptly into consumption.

SHEET BARS TO BE HIGHER

In the actual steel market, the important event in a week of few definite developments was the announcement of the Carnegie Steel Co. of its first-quarter price on sheet bars, at $36.50, or somewhat above the average expectation, since the trade at large had scarcely thought the price would be above $35. The price applies to sheet bars supplied the subsidiary in the Steel Corporation, the American Sheet & Tin Plate Co., and to certain independent mills with which there are long-term contracts under which the Carnegie Steel Co. obligates itself to furnish sheet bars at a price to be named quarterly, the buyer having the privilege of refusing to take the steel in any particular quarter if the price is not considered satisfactory. The Carnegie Steel Co. does not sell sheet bars in the open market. Its price is, however, usually a lead to the independents who sell bars. On Nov. 23, on opening its order books for deliveries after Jan. 1, the American Sheet & Tin Plate Co. reaffirmed its former prices, $4.75 for tin plate, 2.50c. for blue annealed sheets, 3.35c. for black sheets, 4.35c. for galvanized sheets and 4.70c. for automobile sheets. The prospect is further reduced that these prices will be cut. As to automobile sheets, the independents had a 5c. price and are adhering to this figure, which they will probably be able to obtain in sales for first quarter, as the leading interest is filled for first quarter, its present sales being substantially for second quarter.

Bars, shapes and plates continue quotable at a general price of 2c., there being some concessions, as formerly in the case of particularly desirable orders.

Pipe mills have not caught up on deliveries and remain under considerable pressure, particularly in the case of butt weld sizes of merchant pipe, the best delivery on which is eight weeks, in the case of new orders. Wire mills are also under some pressure, particularly in nails.

Connellsville furnace coke for spot shipment is off 50c. in the week, at $6.75@$7. For delivery over the remainder of the year $7 or $7.25 can be done, and one sale at $6.75 is reported.

Valley pig iron has continued to decline in price, as it has been doing for 2 months or more. The week's additional decline is a small item, while the development of some demand, with perhaps two or three fair-sized purchases actually made for first quarter, is a strictly new development. The market now has two sides, even if the new side is thus far but a weak one. The market as quotable is down 50c. on bessemer to $28, 50c. on basic to $25 and $1 on foundry to $25.50, with single carloads generally going at $26, all prices being at valley furnaces, with $1.77 freight to Pittsburgh.

Arsenic Still the Feature of the New York Market

Consuming Interests Are Showing Concern Regarding Present High Prices and Possible Shortage

The manufacturers of insecticides and representatives of the consuming industries are vitally concerned with developments in the arsenic market. It is becoming more and more evident that the successful prosecution of the campaigns now proposed for combating the boll weevil depends primarily on the possibilities of a greatly increased supply of white arsenic. The recent inactivity of the lead and copper smelting industries and the smaller imports from Japan are the principal causes of the current shortage and consequent high prices. Among dealers and second hands the price range has reached 15 to 15½c. per lb., although producers' prices are somewhat under this.

NUMEROUS PRICE CHANGES

Formaldehyde prices were advanced ¾c. per lb., due to the recent increase in methanol quotations. Material at the works is quite scarce and some producers reported a heavily sold-up condition. Manufacturers of iodides announced an increase of 10c. per lb. on all varieties. Producers of oxalic acid have been forced to meet foreign competition and quoted lower prices at the works and for spot material. Prussiates showed a slight tendency to weaken during the interval in the absence of any noticeable activity. The alkali market for domestic consumption was strongly maintained and the volume of contracts for 1923 was quite satisfactory to producers. Bleaching powder was reported very firm at the works. Denatured alcohol was again advanced 2c. per gal.

GENERAL AND SPECIAL CHEMICALS

Arsenic.—The spot market is very strong and supplies are light. Producers report a sold-up condition at the works. The resale range is around 15@15½c. per lb., with domestic producers quoting 12¾c. per lb.

Barium Chloride—Consumers have shown little desire to purchase any round lots and importers are inclined to shade the market. Spot prices are quoted at $90@$95 per ton.

Bichromate of Potash—Producers quote the market around 9¾@10c. per lb. for spot and future shipments. Consumers have shown some desire for 1923 contracts.

Carbonate of Potash—Calcined 80-85 per cent was reported fairly steady at 6c. per lb. Hydrated 80-85 per cent has been quite scarce with holders asking around 7¼c. per lb. for limited quantities.

Caustic Potash—Imported 88-92 per cent material was quoted at 6½c. per lb. Importers offer shipments at 6¼c. per lb., duty paid. Activity was limited to small lot trading.

Caustic Soda—The export market showed very little change and prices remained at $3.50@$3.60 per 100 lb., f.a.s. New York. Domestic business continued along very active lines at 3¾@4c. per lb. ex-store. Producers quote contracts at $2.50 per 100 lb., basis 60 per cent. f.o.b. works in carload lots. A good inquiry was reported.

Formaldehyde—Prices were again increased to 14¼c. per lb. in carload quantities and 14¾c. in less than carlots. Business among resale dealers was somewhat quiet although a heavily sold-up condition at the works was reported. Second-hand lots were quoted at 13¾@14c. spot, ex-store.

Magnesium Sulphate—The market showed complete signs of improvement. Domestic, technical, was quoted at $1.85@$2 per 100 lb. in bags and $2.25 @$2.50 in barrels. Imported, technical, was held at $1.20@$1.30 per 100 lb.

Oxalic Acid—Domestic manufacturers have been forced to reduce prices to 13½c. per lb., f.o.b. works, due to the foreign competition. Imported goods are on the market at 13½c. per lb., ex-warehouse. Domestic goods on spot were held at 14@15c. per lb.

Prussiate of Soda—The spot market was somewhat weaker and sales were recorded for small lots down to 20c. per lb. The general range is 20@21c.

Soda Ash—There has been very little change reported in the export or domestic markets. Light ash, 58 per cent, bags on spot, was quoted at $1.75@$1.80 per 100 lb. Producers reported a very good contract call at $1.20 per 100 lb., basis 48 per cent, f.o.b. works.

VEGETABLE OILS

Linseed Oil—Immediate shipment oil was offered at 85c. per gal., carload basis. January supplies were available at 82c. and January-April at 78c. per gal. Future trading was dormant during the interval.

Coconut Oil—The general tone was rather quiet, but prices kept quite steady. Ceylon type oil at New York held at 8@8¼c. per lb., tank cars, with barrels around 8¾c. per lb.

Corn Oil—Offerings were somewhat limited and the spot market appeared nominal. Sellers were asking 8¾c. per lb., tank cars, for crude in nearby positions. Refined oil was well sustained at 11@11¼c. per lb. in barrels.

Amylacetate tech.	gal.	..... –	2.35 – 2.60
Arsenic, white, powdered	lb.	.15 – .15¼	.15½ – .15¾
Arsenic, red, powdered	lb.	.13½ – .14	.14½ – .15
Barium carbonate	ton	75.00 – 77.00	78.00 – 80.00
Barium chloride	ton	90.00 – 95.00	96.00 – 100.00
Barium dioxide (peroxide)	lb.	.18 – .18½	.19 – .20
Barium nitrate		.08¾ – .08¾	.09 – .09¼
Barium sulphate (precip.) (blanc fixe)	lb.	.04 – .04¼	.04½ – .04¾
Blanc fixe, dry	lb.	.04 – .04½	..... – .....
Blanc fixe, pulp	ton	45.00 – 55.00	..... – .....
Bleaching powder	100 lb.	2.25 – 2.35	2.40 – 3.50
Blue vitriol (see copper sulphate)		..... –	..... – .....
Borax	lb.	.05½ – .05¾	.06 – .06¾
Brimstone (see sulphur, roll)		..... –	..... – .....
Bromine	lb.	.27 – .28	.28½ – .35
Calcium acetate	100 lb.	3.50 – 3.60	3.65 – 3.75
Calcium carbide	lb.	.04½ – .04¾	.05 – .05½
Calcium chloride, fused, lump	ton	22.00 – 23.00	23.50 – 27.00
Calcium chloride, granulated	lb.	.01½ – .01¾	.02 – .02¼
Calcium peroxide	lb.	..... –	1.40 – 1.50
Calcium phosphate, tribasic	lb.	..... –	.15 – .16
Camphor	lb.	..... –	.93 – .95
Carbon bisulphide	lb.	.06¾ – .07	.07¼ – .07½
Carbon tetrachloride, drums	lb.	.10 – .10½	.10½ – .12
Carbonyl chloride, (phosgene)	lb.	..... –	.60 – .75
Caustic potash (see potassium hydroxide)		..... –	..... – .....
Caustic soda (see sodium hydroxide)		..... –	..... – .....
Chalk, precip.—domestic, light	lb.	.04¼ – .04½	..... – .....
Chalk, precip.—domestic, heavy	lb.	.03½ – .03¾	..... – .....
Chalk, precip.—imported, light	lb.	.04½ – .05	..... – .....
Chlorine, gas, liquid-cylinders (100 lb.)	lb.	.05¼ – .06	.06¼ – .06½
Chloroform	lb.	..... –	.35 – .38
Cobalt oxide	lb.	..... –	2.10 – 2.40
Copperas	ton	25.00 – 27.00	27.50 – 30.00
Copper carbonate, green precipitate	lb.	.20 – .20½	.21 – .22
Copper cyanide	lb.	..... –	.50 – .55
Copper sulphate, crystals	100 lb.	5.75 – 6.00	6.10 – 6.50
Cream of tartar	lb.	..... –	.25½ – .26
Epsom salt (see magnesium sulphate)		..... –	..... – .....
Ether, U.S.P. 100 drums	lb.	..... –	.13 – .14
Ethyl acetate com. 85%	gal.	..... –	.72 – .75
Ethyl acetate, pure (acetic ether, 98% to 100%)	gal.	..... –	.90 – .95
Formaldehyde, 40 per cent	lb.	.14¼ – .14½	.14¾ – .15
Fullers earth, f.o.b. mines	net ton	16.00 – 17.00	..... – .....
Fullers earth—imported powdered	net ton	30.00 – 32.00	..... – .....
Fuse oil, ref.	gal.	..... –	3.00 – 3.50
Fusel oil, crude	gal.	..... –	2.00 – 2.25
Glauber's salt (see sodium sulphate)		..... –	..... – .....
Glycerine, c.p. drums extra	lb.	..... –	.18½ – .18¾
Iodine, resublimed	lb.	..... –	4.50 – 4.60
Iron oxide, red	lb.	..... –	.12 – .18
Lead acetate, white crystals	lb.	..... –	.12 – .12½
Lead arsenate, powd.	lb.	.14 – .14¼	4½ – .15
Lead nitrate	lb.	..... –	.18 – .22
Litharge	lb.	.09¼ – .09¾	.09¾ – .10
Magnesium carbonate, technical	lb.	.07 – .07½	.07½ – .08
Magnesium sulphate, U.S.P.	100 lb.	2.50 – 2.65	2.70 – 3.50
Magnesium sulphate, technical	100 lb.	..... –	1.20 – 1.85
Methanol, 95%	gal.	..... –	1.00 – 1.07
Methanol, 97%	gal.	..... –	1.03 – 1.10
Nickel salt, double	lb.	..... –	$0.10 – $0.10½
Nickel salt, single	lb.	..... –	.11 – .11½
Phogene (see carbonyl chloride)		..... –	..... – .....
Phosphorus, red	lb.	..... –	.35 – .40
Phosphorus, yellow	lb.	..... –	.30 – .35½
Potassium bichromate	lb.	$0.09⅜ – .10	.10¼ – .10½
Potassium bromide, granular	lb.	..... –	.17 – .23
Potassium carbonate, U. S. P.	lb.	.10 – .10½	.11 – .15
Potassium carbonate, 80–85%	lb.	.06 – .06¼	.06½ – .06¾
Potassium chlorate, powdered and crystals	lb.	.07½ – .08	.08¼ – .09
Potassium cyanide	lb.	..... –	.50 – .53
Potassium hydroxide (caustic potash)	100 lb.	6.50 – 6.60	6.65 – 7.00
Potassium iodide	lb.	..... –	3.55 – 3.65
Potassium nitrate	lb.	.06½ – .06¾	.07 – .08
Potassium permanganate	lb.	.16 – .16½	.16½ – .17
Potassium prussiate, red	lb.	..... –	.93 – .95
Potassium prussiate, yellow	lb.	.39 – .39½	.39¾ – .40
Rochelle salts (see sodium potas. tartrate)		..... –	..... – .....
Salammoniac, white, granular	lb.	.06½ – .06¾	.07 – .07½
Salammoniac, gray, granular	lb.	.08 – .08¼	.08¾ – .08¾
Salsoda	100 lb.	1.20 – 1.40	1.45 – 1.60
Salt cake (bulk)	ton	25.00 – 27.00	..... – .....
Soda ash, light, 58 per cent flat, bags, contract	100 lb.	1.60 – 1.67	2.00 – 2.25
Soda ash, light, 58 per cent flat, bags, resale	100 lb.	1.75 – 1.80	1.85 – 2 35
Soda ash, dense, in bags, resale	100 lb.	1.85 – 1.90	1.95 – 2.40
Sodium acetate	lb.	.07½ – .07¾	.08 – .08½
Sodium bicarbonate	100 lb.	1.75 – 1.85	1.90 – 2.30
Sodium bichromate	lb.	.07½ – .07¾	.08 – .08½
Sodium bisulphite (nitre cake)	ton	4.50 – 4.60	4.65 – 5.50
Sodium bisulphite powdered, U.S.P.	lb.	.04¼ – .04½	.04¾ – .05¼
Sodium chlorate	lb.	.06¾ – .07	.07¼ – .07½
Sodium chloride	long ton	12.00 – 13.00	..... – .....
Sodium cyanide	lb.	.19½ – .21	.21½ – .25
Sodium fluoride	lb.	.09¼ – .09½	.09¾ – .10
Sodium hydroxide (caustic soda) solid, 76 per cent flat, drums, contract	100 lb.	3.35 – 3.40	3.75 – 4.00
Sodium hydroxide (caustic soda) solid, 76% flat, drums, resale	100 lb.	3.50 – 3.60	3.65 – 4.00
Sodium hydroxide (caustic soda), ground and flake, contracts	100 lb.	3.80 – 3.90	4.25 – 4.40
Sodium hydroxide (caustic soda) ground and flake, resale	100 lb.	4.00 – 4.15	4.40 – 4.60
Sodium hyposulphite	lb.	.03 – .03¼	.03½ – .04
Sodium nitrite	lb.	.08¼ – .09	.09½ – .09½
Sodium peroxide, powdered	lb.	.28 – .30	.31 – .35
Sodium phosphate, dibasic	lb.	.03½ – .04	.04¼ – .04½
Sodium potassium tartrate (Rochelle salts)	lb.	..... –	.18 – .21
Sodium prussiate, yellow	lb.	.20 – .20½	.20¾ – .21½
Sodium silicate, (40 deg. in drums)	100 lb.	1.25 – 1.30	1.35 – 1.50
Sodium silicate, (60 deg. in drums)	100 lb.	2.25 – 2.40	2.45 – 2.75
Sodium sulphate, crystals (glaubers salt)	100 lbs.	.85 – .95	1.00 – 1.40
Sodium sulphide, fused, 60-62 per cent (conc.)	lb.	.04¼ – .04½	.05 – .05½
Sodium sulphite, crystals	lb.	.03½ – .03⅝	.03¾ – .04¼
Strontium nitrate, powdered	lb.	.09½ – .10	.10¼ – .12
Sulphur chloride, yellow	lb.	.04½ – .05	.05¼ – .06
Sulphur, crude	ton	18.00 – 20.00	..... – .....
Sulphur dioxide, liquid, cylinders extra	lb.	.08 – .08½	.09 – .10
Sulphur (sublimed), flour	100 lb.	..... –	2.50 – 3.15
Sulphur, roll (brimstone)	100 lb.	2.15 – 2.20	2.25 – 2.75
Talc—imported	ton	30.00 – 40 00	..... – .....
Talc—domestic powdered	ton	18.00 – 25.00	..... – .....
Tin bichloride	lb.	.10½ – .10¾	.11 – .11½
Tin oxide	lb.	..... –	.43 – .45
Zinc carbonate	lb.	.14 – .14½	.14¾ – .15½
Zinc chloride, gran.	lb.	.07 – .07½	.07¾ – .08
Zinc cyanide	lb.	.42 – .44	.45 – .47
Zinc oxide, XX	lb.	.07½ – .08	.08¼ – .08½
Zinc sulphate	100 lb.	2.75 – 3.00	3.05 – 3.30

Coal-Tar Products

NOTE—These prices are for original packages in large quantities f.o.b. N.Y.:

Alpha-naphthol, crude	lb.	$0.90 — $0.95
Alpha naphthol, refined	lb.	1.00 — 1.05
Alpha-naphthylamine	lb.	.28 — .30
Aniline oil, drums extra	lb.	.16 — .17
Aniline salts	lb.	.22 — .24
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00½
Anthracene, 80%, imported in drums, duty paid	lb.	.65 — .70½
Benzaldehyde U.S.P.	lb.	1.25 — 1.35
Benzene, pure, water-white, in drums (100 gal.)	gal.	.30 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.28 — .32
Benzene, 90%, in drums, resale	gal.	.37 — .40
Benzidine, base	lb.	.85 — .90
Benzidine sulphate	lb	.75 — .80
Benzoic acid, U.S.P.	lb.	.72 — .75
Benzoate of soda, U.S.P.	lb.	.57 — .65
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech.	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.55 — .60
Beta-naphthol, tech	lb.	.25 — .26
Beta-naphthyla mine, technical	lb.	1.00 — 1.25
Carbazol	lb.	.75 — .90
Cresol, U. S. P., in drums (100 lb.)	lb.	.14 — .20
Ortho-cresol, in drums (100 lb.)	lb.	.18 — .22
Cresylic acid, 97–99%, straw color, in drums	gal.	.60 — .65
Cresylic acid, 95-97%, dark, in drums	gal.	.55 — .58
Cresylic acid, 97%, resale	gal.	.85 — .90
Dichlorbenzene	lb.	.07 — .09
Diethylaniline	lb.	.50 — .60
Dimethylaniline	lb.	.39 — .41
Dinitrobenzene	lb.	.20 — .22
Dinitroclorbenzene	lb.	.22 — .23
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.32 — .34
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.25 — .30
Diphenylamine	lb.	.54 — .56
H-acid	lb.	.75 — .80
Meta-phenylenediamine	lb.	.90 — 1.00
Monochlorbenzene	lb.	.08 — .10
Monoethylaniline	lb.	.95 — 1.10
Naphthalene crushed, in bbls.	lb.	.06 — .06
Naphthalene, flake	lb.	.06 — .06

Naphthalene, balls	lb.	$0.07 —	$0.07
Naphthionate of soda	lb.	.58 —	.65
Naphthionic acid, crude	lb.	.65 —	.70
Nitrobenzene	lb.	.10 —	.12
Nitro-naphthalene	lb.	.30 —	.35
Nitro-toluene	lb.	.15 —	.17
N-W acid	lb.	1.20 —	1.30
Ortho-amidophenol	lb.	2.25 —	2.30
Ortho-dichlor-benzene	lb.	.17 —	.20
Ortho-nitro-phenol	lb.	.85 —	.90
Ortho-nitro-toluene	lb.	.10 —	.12
Ortho-toluidine	lb.	.12 —	.14
Para-amidophenol, base	lb.	1.20 —	1.25
Para-amidophenol, HCl	lb.	1.25 —	1.30
Para-dichlorbenzene	lb.	.17 —	.20
Paranitroaniline	lb.	.72 —	.80
Para-nitrotoluene	lb.	.55 —	.65
Para-phenylenediamine	lb.	1.50 —	1.55
Para-toluidine	lb.	.85 —	.90½
Phthalic anhydride	lb.	.37 —	.50
Phenol, U. S. P., drums	lb.	.34 —	.35
Pyridine, domestic	gal.	1.60 —	1.75
Pyridine, imported	gal.	1.40 —	1.60
Resorcinol, technical	lb.	1.50 —	1.55
Resorcinol, pure	lb.	2.00 —	2.10
R-salt	lb.	.55 —	.60
Salicylic acid, tech., in bbls.	lb.	.35 —	.37
Salicylic acid, U. S. P.	lb.	.40 —	.42
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.37 —	.40
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.20 —	.23
Sulphanilic acid, crude	lb.	.24 —	.26
Tolidine	lb.	1.20 —	1.30
Toluidine, mixed	lb.	.30 —	.35
Toluene, in tank cars	gal.	.35 —	.37
Toluene, in drums	gal.	.40 —	.43
Xylidines, drums, 100 gal.	lb.	.40 —	.45
Xylene, pure, in drums	gal.	.45 —	.50
Xylene, pure, in tank cars	gal.	.45 —	....
Xylene, commercial, in drums, 100 gal	gal.	.40 —	.42
Xylene, commercial, in tank cars	gal.	.30 —	....

Waxes

Prices based on original packages in large quantities f.o.b. N.Y.

Bayberry Wax	lb.	$0.28 —	$0.30
Beeswax, refined, dark	lb.	.30 —	.32
Beeswax, refined, light	lb.	.34 —	.35
Beeswax, pure white	lb.	.39 —	.40
Candellila, wax	lb.	.34 —	.35
Carnauba, No. 1	lb.	.39 —	.40
Carnauba No. 2, North Country	lb.	.23 —	.24
Carnauba, No. 3, North Country	lb.	.17½ —	.18
Japan	lb.	.15 —	.15½
Montan, crude	lb.	.03½ —	.04
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.04 —	.04¾
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.02½ —	.02½
Paraffine waxes, refined, 118-120 m.p.	lb.	.03¼ —	.03½
Paraffine waxes, refined, 125 m.p.	lb.	.03½ —	.03½
Paraffine waxes, refined, 128-130 m.p.	lb.	.04 —	.04¾
Paraffine waxes, refined, 133-135 m.p.	lb.	.04½ —	.04¾
Paraffine waxes, refined, 135-137 m.p.	lb.	.05 —	.05¼
Stearic acid, single pressed	lb.	.09 —	.09½
Stearic acid, double pressed	lb.	.09½ —	.09¾
Stearic acid, triple pressed	lb.	.10 —	.10½

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl	280 lb.	$6.25 —	....
Rosin E-I	280 lb.	6.35 —	....
Rosin K-N	280 lb.	6.45 —	$7.00
Rosin W. G.-W. W	280 lb.	7.75 —	8.25
Wood rosin, bbl	280 lb.	6.25 —	....
Spirits of turpentine	gal.	1.40 —	1.42
Wood turpentine, steam dist	gal.	1.35 —	....
Wood turpentine, dest. dist	gal.	1.25 —	....
Pine tar pitch, bbl	200 lb.	..... —	6.00
Tar, kiln burned, bbl. (500 lb.)	bbl.	..... —	12.50
Retort tar, bbl	500 lb.	..... —	11.00
Rosin oil, first run	gal.	.43 —	....
Rosin oil, second run	gal.	.51 —	....
Rosin oil, third run	gal.	.53 —	....
Pine oil, steam dist., sp.gr., 0.930-0.940	gal.		.90
Pine oil, pure, dest. dist	gal.		.85
Pine tar oil, ref., sp.gr. 1.025-1.035	gal.		.46
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla	gal.		.35
Pine tar oil, double ref., sp.gr. 0.965-0.990	gal.		.75
Pine tar, ref., thin, sp.gr., 1.080-1.960	gal.		.25
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990	gal.		.25
Pine wood creosote, ref	gal.		.52

Fertilizers

All prices remain same as previous report.

Crude Rubber

Para—Upriver fine	lb.	$0.25 —	.25½
Upriver coarse	lb.	.17½ —	.17¾
Upriver caucho ball	lb.	.20¾ —	.20¾
Plantation—First latex crepe	lb.	.27¾ —	.27¼
Ribbed smoked sheets	lb.	.27¼ —	.27½
Brown crepe, thin, clean	lb.	.23 —	.23½
Amber crepe No. 1	lb.	.23 —	.23¼

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls	lb.	$0.12 —	$0.12½
Castor oil, AA, in bbls	lb.	.12½ —	.13
China wood oil, in bbls	lb.	.12½ —	.12½
Coconut oil, Ceylon grade, in bbls	lb.	.08⅝ —	.08¾
Coconut oil, Cochin grade, in bbls	lb.	.09 —	.09¼
Corn oil, crude, in bbls	lb.	.10¼ —	.10½
Cottonseed oil, crude (f. o. b. mill)	lb.	.08½ —	....
Cottonseed oil, summer yellow	lb.	.10 —	.10½
Cottonseed oil, winter yellow	lb.	.11 —	.11½
Linseed oil, raw, car lots (domestic) bbls	gal.	.85 —	.86
Linseed oil, raw, tank cars (domestic)	gal.	.81 —	.82
Linseed oil, boiled, in 5-bbl lots (domestic)	gal.	.87 —	.89
Olive oil, denatured	gal.	1.12 —	1.15
Palm, Lagos	lb.	.07½ —	.07½
Palm, Niger	lb.	.07 —	.07¼
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.11 —	.11¼
Peanut oil, refined, in bbls	lb.	.13¾ —	.14
Rapeseed oil, refined in bbls	gal.	.78 —	.79
Rapeseed oil, blown, in bbls	gal.	.84 —	.85
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.11½ —	....
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.09¼ —	.09½

FISH

Light pressed menhaden	gal.	$0.54 —	....
White bleached menhaden	gal.	.58 —	.59
Blown menhaden	gal.	.64 —	.65
Whale Oil, No. 1. crude, tanks, coast	gal.	.45 —	.48

Miscellaneous Materials

Shellac, orange fine	lb.	.76 —	.77
Shellac, orange superfine	lb.	.78 —	.79
Shellac, A. C. garnet	lb.	.77 —	.78
Shellac, T. N.	lb.	.74 —	.75

Ferro-Alloys

Ferrotitanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	$200.00 —	$225.00
Ferrochromium, per lb. of Cr contained, 6-8% carbon, carlots	lb.	.11 —	.11½
Ferrochromium, per lb. of Cr contained, 4-6% carbon, carlots	lb.	.11½ —	.12
Ferromanganese, 78-82% Mn, Atlantic seaboard duty paid	gross ton	100.00 —	105.00
Spiegeleisen, 19-21% Mn	gross ton	36 00 —	37.00
Ferromolybdenum, 50-60% Mo, per lb. of Mo	lb.	2.00 —	2.25
Ferrosilicon, 10-15%	gross ton	38.00 —	40.00
Ferrosilicon, 50%	gross ton	75 00 —	80.00
Ferrosilicon 75%	gross ton	115.00 —	120.00
Ferrotungsten, 70-80%, per lb. of contained W	lb.	.90 —	.95
Ferro-uranium, 35-50% of U, per lb. of U content	lb.	6.00 —	.....
Ferrovanadium, 30-40% per lb. of contained V.	lb.	3.50 —	4.00

Ores and Semi-finished Products

All f.o.b. New York Unless Otherwise Stated

Bauxite, domestic, crushed and dried, f.o.b. shipping points	net ton	$6.00 —	$9.00
Chrome ore, Calif. concentrates, 50% min. Cr_2O_3	ton	22.00 —	23.00
Chrome ore, 50% Cr_2O_3, c.i.f. Atlantic seaboard	ton	18 50 —	19.00
Coke, foundry, f.o.b. ovens	net ton	7.50 —	8 00
Coke, furnace, f.o.b. ovens	net ton	7.00 —	7.25
Fluorspar, gravel, f.o.b. mines, New Mexico	net ton	17 50 —	.....
Fluorspar, standard, domestic washed gravel Kentucky and Illinois mines	net ton	21.50 —	22.00
Ilmenite, 52% TiO_2, per lb. ore	lb.	.01½ —	.01½
Manganese ore, 50% Mn, c.i.f. Atlantic seaport	unit	.45 —	.....
Manganese ore, chemical (MnO_2)	net ton	75.00 —	80.00
Molybdenite, 85% MoS_2, per lb. of MoS_2, N. Y.	lb.	.80 —	.85
Monazite, per unit of ThO_2, c.i.f., Atlantic seaport.	lb.	.06 —	.08
Pyrites, Spanish, fines, c.i.f., Atlantic seaport	unit	.11½ —	.12
Pyrites, Spanish, furnace size, c.i.f. Atlantic seaport	unit	.11½ —	.12
Pyrites, domestic, fines, f.o.b. mines, Ga	unit	Nominal	
Rutile, 95% TiO_2 per lb. ore	lb.	.12 —	.....
Tungsten, scheelite, 60% WO_3 and over, per unit of WO_3 (nominal)	unit	8.50 —	8.75

Financial, Construction and Manufacturers' News

Construction and Operation

California

LOS ANGELES—The Comet Oil Co., recently organized with a capital of $600,000, has acquired property on East 26th St., near Downey Rd., as a site for a new oil-refining plant with initial capacity of about 2,500 bbl. It is estimated to cost in excess of $500,000. J. J. Gans, Michael Gore and Adolph Ramish head the company.

SAN DIEGO—The Shell Oil Co., 343 Sansome St., San Francisco, is arranging for the purchase of property on the tidelands for the erection of a new oil storage and distributing plant, to consist of two 25,000-gal. capacity tanks, pumping plant, pipe lines, etc. The company is also preparing to commence work on a similar plant on Front St., Ventura, with initial storage and distributing facilities for 75,000 gal.

SAN FRANCISCO—The De Boom Paint Co., 561 Clay St., has awarded a contract to James Furlong, Monadnock Bldg., for the erection of a new 2-story building on Commercial St., to cost approximately $20,000.

Connecticut

DANBURY—The Transloid Products Co., recently organized, has acquired the factory of the Warner Brothers Co., on East Liberty St., for the establishment of a new plant for the manufacture of composition products, known as Transloid. Machinery will be installed at once and operations placed under way. Charles Hetzel is president and general manager.

Florida

TAMPA—The Imperial Oil Co., 6006 Branch Ave., has awarded a general contract to William Kohler, 33rd St. and 14th Ave., for the erection of the initial buildings for its proposed new local plant for the production of lubricating oils. A list of machinery to be installed is being arranged, to include agitators, oil-blending apparatus, pumping equipment, tanks, etc., providing for a capacity of 500 gal. per day. W. F. Miller is president, and A. M. Allen, general manager.

BRADENTOWN—The local Board of Trade is perfecting plans for the construction of an artificial gas plant for service in this section. It is proposed to organize a company to operate the property, which is expected to be headed by C. N. Turner, proprietor of the Braden Hotel.

Idaho

NAMPA—The Board of Directors of the local Chamber of Commerce is considering plans for the establishment of a new starch-manufacturing plant, to cost about $40,000, with initial equipment. It is purposed to organize a company to operate the factory.

Illinois

CHICAGO—G. K. Nikolas & Co., 1227 West Van Buren St., manufacturers of lacquers, etc., are taking bids for the construction of a 3-story and basement plant addition, 50x70 ft., estimated to cost approximately $50,000. Meyer & Cook, 30 North Dearborn St., are architects.

Louisiana

NEW ORLEANS—The Union Carbide Co., 30 East 42nd St., New York, has perfected plans for plant additions for its subsidiaries, the Prest-O-Lite Co. and the Linde Air Products Co. The first noted will soon break ground for the erection of a large acetylene plant on site acquired some time ago on Upperline St., fronting on the 17th St. canal, estimated to cost in excess of $[illegible]. The Linde company, manufacturer of industrial oxygen, etc., has work under way on a new plant at St. Louis and North Anthony Sts., to cost more than $[illegible]. It is expected to have the latter [illegible] ready for the machinery installation early in the coming year.

Maryland

BALTIMORE—The Air Reduction Co., 342 Madison Ave., New York, will take bids at once for the erection of its proposed new local plant on Fayette St., near 11th St., for the manufacture of industrial oxygen, oxy-acetylene apparatus, etc., estimated to cost about $150,000, of which amount more than $85,000 will be used for equipment. Francisco & Jacobus, 511 5th Ave., New York, are consulting engineers.

Massachusetts

EAST WALPOLE—Bird & Son, Inc., 185 Devonshire St., Boston, manufacturer of prepared roofing, paper products, etc., has plans in progress for the construction of a new plant addition. Monks & Johnson, 99 Chauncey St., Boston, are architects.

FALL RIVER—The Standard Oil Co., foot of Slade St., has commenced the erection of a new distributing plant to cost about $37,000.

Michigan

SAULTE STE. MARIE—The Union Carbide Co., 30 East 42nd St., New York, will soon commence the erection of an addition to its local plant for considerable increase in capacity, to include a number of improvements in the present works, designed to give employment to an additional working force of about 300 operatives. A new set of kilns will be constructed. The expansion, with equipment, is estimated to cost about $500,000.

PALMYRA—The Simplex Paper Co. has commissioned the Austin Co., 16112 Euclid Ave., Cleveland, O., engineer and contractor, to prepare plans for a new local plant, to include power house, estimated to cost close to $100,000.

PETOSKEY—The Petoskey Portland Cement Co. is planning for the rebuilding of the portion of its plant, including laboratory, machine shop and other structures, destroyed by fire, Nov. 19, with loss of about $50,000. The work will be carried out in connection with the proposed new plant additions, estimated to cost close to $500,000.

MARYSVILLE—The Athol Mfg. Co., manufacturer of rubberized products, is planning for enlargements in its plant, to include the installation of additional equipment. It is purposed to add to the present line of production.

MONROE—The Consolidated Paper Co., East Elm St., has preliminary plans under way for the construction of a new mill for the production of strawboard and kindred specialties. W. C. Tullis is secretary.

PONTIAC—The Wilson Foundry & Machine Co. will commence the immediate erection of a new 1-story addition, 36x50 ft., to be equipped as a testing laboratory.

DETROIT—The Huron Portland Cement Co., Ford Bldg., has preliminary plans under way for the rebuilding of its local distributing plant at Atwater and Riopelle Sts., recently destroyed by fire. The new structure is estimated to cost in excess of $100,000. J. W. Boardman is vice-president.

New Jersey

KEARNY — The Egyptian Lacquer Co., Passaic Ave., has awarded a contract to the United Fireproofing Co., 8 West 40th St., New York, for the erection of a 3-story plant addition to cost about $37,000. Work will be placed under way at once.

ELIZABETH—The T. G. & M. Chemical Co., 517 Cortland St., Belleville, N. J., has leased the former factory of the Loewenstein Radio Co., on Meadow Lane, for the establishment of a new plant. Improvements will be made in the building and equipment installed at an early date. It is planned to remove the present works to the new location.

JERSEY CITY—Work will be placed under way at once on a new 1-story foundry at the plant of the M. W. Kellogg Co., Hackensack Ave., manufacturer of pipe, pipe bends, etc., estimated to cost $50,000.

NEWARK—The Blackstone Mfg. Co., 203 Johnston Ave., manufacturer of food colors, etc., has filed plans for the erection of a new 3-story plant at 206-10 Johnston Ave., to cost $25,000.

BAYONNE—The Vacuum Oil Co., 61 Broadway, New York, is taking bids for the erection of a 2-story storage and distributing building at its local refinery, 75x190 ft.

NEWARK—Fire, Nov. 25, destroyed a portion of the leather tannery of Kaufherr & Siegel, Ave. L and Magazine St., with loss estimated at about $45,000, including equipment and stock. It is planned to rebuild at once.

NEWARK—Louis Sacks, Wilson Ave., operating a foundry for the production of gray iron castings, has filed plans for the erection of a 1-story foundry addition, to cost about $13,000.

New York

LONG ISLAND CITY—The Liberty Paint Co., 39 10th St., has filed plans for the immediate erection of a new 2-story plant, 100x100 ft., estimated to cost about $100,000.

NEW YORK—The International Petroleum Co., 120 Broadway, has commenced work on a new oil project in the South American oil fields, comprising a pipe line, pumping plants, distributing and storage plants, and other structures to cost in excess of $15,000,000, with equipment. The company is associated with other oil interests in the enterprise, including the Leonard Oil Development Co., Transcontinental Oil Co., Colombia Syndicate, and affiliations of the Standard Oil Co.

Ohio

CUYAHOGA FALLS—The Common Council is considering tentative plans for the installation of a filtration plant at the city waterworks for the removal of excess iron from the municipal water.

CAMBRIDGE—The plant and property of the Florentine Pottery Co., East Cambridge, owned by the Pfau Mfg. Co., Cincinnati, now in charge of a trustee in bankruptcy, has been purchased by E. S. Romaine, Wheeling, W. Va., for a consideration of $50,000. The new owner is said to be planning to organize a company and operate at the plant.

Oklahoma

OKMULGEE—The Phillips Higrade Refining Co. has plans nearing completion for extensions and improvements in its local oil refinery, to include the installation of new recovery systems, bleacher and run-down tanks, power plant apparatus, and other equipment, estimated to cost close to $500,000. Work will be placed under way at an early date.

OKLAHOMA CITY—The Board of Works has commenced extensions and improvements in the local water system, to include a new filtration plant, estimated to cost in excess of $1,000,000.

TULSA—The Taylor Paper Co., Memphis, Tenn., is planning for the establishsment of a new branch plant here to cost approximately $100,000, including equipment.

Pennsylvania

PHILADELPHIA—The United Oxygen Mfg. Co., Westmoreland and B Sts., will break ground at once for the erection of a new 1-story plant, 25x45 ft., on Buckius St., near Richmond Ave. The general building contract has been let to George Tomlinson & Son, 1713 Sansom St., Philadelphia.

PHILADELPHIA—The Kohler Co., Kohler, Wis., manufacturer of sanitary ware and other pottery products, has acquired property at Turner and 32nd Sts., totaling about 15,000 sq.ft., as a site for the erection of a new 3-story branch plant. Plans will be placed under way at once.

PITTSBURGH—The Vitro Mfg. Co., Bessemer Bldg., manufacturer of enamels, dioxide, etc., is completing plans for the erection of a new 1-story plant addition, 32x45 ft., on Oliffe St.

PHILADELPHIA—The Great Eastern Mills Co., 440 7th Ave., Pittsburgh, has leased two buildings at 939-41 North Front St., for the establishment of a new mill for the manufacture of pulverized sugar.

PHILADELPHIA—The Pecora Paint Co., 4th and Sedgley Sts., has filed plans for the erection of a new 1-story building at its plant at 3rd and Sedgley Sts.

BRISTOL—The Megargee Paper Mills, Inc., Modena, Pa., is taking title to a tract of local property, totaling about 70 acres, for a consideration of about $60,000, to be used as a site for a new paper mill. Plans are under way for the initial plant unit, to consist of a number of buildings. It is expected to commence work at an early date.

PHILADELPHIA—The Continental Leather Co., 315 North 3rd St., will commence the immediate erection of a 1-story addition to its tannery at Tacony and Van Kirk

Sts. The general contract has been let to the Truscon Steel Co., 1432 South Penn Sq.

Tennessee

KNOXVILLE — The Knox Porcelain Co., recently organized with a capital of $370,000, to manufacture electrical porcelain products, will break ground at once for a new 3-unit plant, on tract of local property, comprising about 5 acres of land. It will be equipped for a daily production of close to 75,000 small porcelain specialties. J. N. House is president.

COLUMBIA — The Greenway Co., J. B. Greenway, general manager, has acquired a large tract of land on the Culleika Pike, and will use the site for a new plant for the manufacture of automobile tires, estimated to cost about $150,000.

Texas

RANGER—The Straits Oil Co., operating on the Barker property, about 6 miles from Ranger, is planning for extensions in its casinghead gasoline plant to cost about $25,000. The capacity will be considerably increased.

TEXAS CITY—The Marland Oil & Refining Co., Ponca City, Okla., is planning for the purchase of a site in this vicinity, on the waterfront, for the construction of a new storage and distributing plant, estimated to cost in excess of $100,000.

Virginia

BIG ISLAND—The Bedford Pulp & Paper Co., Richmond, has revised plans in preparation for the erection of a 3-story addition to its local paper mill, 60x140 ft., estimated to cost approximately $35,000, exclusive of equipment. The company has recently arranged for a bond issue of $800,000, a portion of the proceeds to be used for general expansion. Milton E. Marcuse is president. Charles K. Bryant, 1808 Hanover Ave., Richmond, is architect for the new mill extension.

STRASBURG — The Hy-Grade Manganese Co., Woodstock, Va., has acquired a building at East Strasburg, for the establishment of a new mill. The structure will be remodeled and improved, and equipment installed, including a grinding mill, power apparatus, etc. J. C. Ackerson is general manager.

NORFOLK—The Fisheries Products Corp. has tentative plans under way for the erection of a 1-story plant, 245x300 ft., at its site at Money Point, for the manufacture of fertilizer products, to replace the portion of the works recently destroyed by fire. The new structure, with equipment, is estimated to cost about $200,000. Headquarters of the company are at 50 Broad St., New York.

BIG STONE GAP—W. W. Taylor is arranging for the organization of a company to construct and operate a local plant for the manufacture of brick and other burned clay products. Daniel Bostic, Big Stone Gap, is also interested in the project.

GLASGOW — The Glasgow Clay Products Co. is planning for the installation of a rotary drier at its plant, with capacity of about 10 tons of shale per hour.

Washington

SEATTLE — In addition to extension and improvement work now in progress at its storage and distributing plant, to cost about $200,000, the Associated Oil Co., 1733 Railroad Ave., has plans in progress for additional work, including steel tanks, etc., estimated to cost about $150,000. A. J. McNeil, 207 White Bldg., is resident engineer for the company.

West Virginia

HALLTOWN—The Halltown Paper Board Co. is planning for the rebuilding of the portion of its plant, including power house, recently destroyed by fire.

FOLLANSBEE — The Jefferson Glass Co., manufacturer of illuminating glassware, is arranging a fund of $150,000, the proceeds to be used for extensions and improvements in its local plant. A portion of the structure will be remodeled and additional equipment installed. C. H. Blumenauer is president.

WARWOOD—The Centre Foundry & Machine Co. has awarded a contract for the immediate erection of a new 1-story foundry at its works, 100x320 ft., to be equipped for the production of gray iron castings. It will have a capacity of about 50 tons per day. F. H. Young is general manager.

Wisconsin

MILWAUKEE—The Pfister & Vogel Leather Co., 443 Virginia St., has awarded a contract to the Dahlman Construction Co., 456 Broadway, for the erection of a 1-story addition to its tannery, 63x63 ft. Work will be commenced at once.

MILWAUKEE—The Palmolive Co., manufacturer of soaps, has work under way on a 1-story addition to its plant, 50x80 ft., to be used for general increase in production. Lockwood, Greene & Co., Chicago, Ill., are engineers.

New Companies

THE KENWOOD WAX PAPER MILLS, INC., 4761 West Hipple Ave., Chicago, Ill., has been incorporated with a capital of $150,000, to manufacture plain and waxed papers. The incorporators are Louis G. Berman, Alfred G. Johnson and Otto C. Bruhlman.

THE STA-BRITE CO., New York, N. Y., care of the Delaware Registration & Incorporating Co., 2 Rector St., New York, representative, has been incorporated under Delaware laws, with a capital of $100,000, to manufacture paints, varnishes, etc. The incorporators are Joseph V. Burns and G. I. Lewis.

THE AUTOMATIC GLASS PRODUCTS CO., Toledo, O., has been incorporated with a capital of $150,000, to manufacture glass specialties. The incorporators are Charles H. Lemmon and M. J. Warner, both of Toledo.

THE AMERICAN DENATURING CORP., New York, N. Y., care of Wallace & Thatcher, Albany, N. Y., representatives, has been incorporated with a capital of $50,000, to manufacture industrial alcohol and kindred products. The incorporators are L. H. Washburn, K. M. Smith and T. J. Mattimore, New York.

THE RAYNAUD-CONRAD PAINT CO., New Orleans, La., care of the Delaware Registration Trust Co., 900 Market St., Wilmington, Del., representative, has been incorporated under Delaware laws, with a capital of $1,100,000, to manufacture paints, varnishes, oils, etc. The incorporators are Joseph Raynaud, C. Carlisle Conrad and George Steele, all of New Orleans.

THE WILLIAM J. SWEET FOUNDRY CO., Bayonne, N. J., has been incorporated with a capital of $15,000, to manufacture iron, steel and other metal castings. The incorporators are William J. Sweet, Charles V. Bruno and Harry A. Cooper, 12 East 34th St., Bayonne. The last noted represents the company.

THE SHERATONE PRODUCTS CORP., New York, N. Y., care of G. W. Phillips, 295 West 144th St., New York, representative, has been incorporated with a capital of $50,000, to manufacture polishes, chemical preparations, etc. The incorporators are W. H. Naugle and W. K. Rishel.

THE WEST COAST CHEMICAL CORP., San Francisco, Calif., has been incorporated with a capital of $300,000, to manufacture chemicals and chemical byproducts. The incorporators are P. E. and Henry P. Adams, Homer Lingenfelter and Clarence E. Todd, Hobart Bldg., San Francisco. The last noted represents the company.

THE BLUE RIDGE OXIDE CO., Allentown, Pa., has been incorporated with a capital of $30,000, to manufacture oxides, chemical products, etc. H. S. Hartzell, Allentown, is treasurer and representative.

THE LIBERTY MIRROR WORKS, INC., Pittsburgh, Pa., is being organized under state laws, to manufacture mirrors, glass novelties, etc. Application for a state charter will be made on Dec. 22. The company is headed by George F. and William H. Colbert, and Benjamin H. Thompson, 1209 First National Bank Bldg., Pittsburgh. The last noted represents the company.

THE LUFBERRY CO., INC., Bayonne, N. J., has been incorporated with a capital of $100,000, to manufacture chemicals and chemical byproducts. The incorporators are A. D. Harz, Burgess A. and Percival G. Cruden, 1 West 8th St., Bayonne. The last noted represents the company.

THE NATIONAL CONSUMERS' PAPER CORP., New York, N. Y., care of Horowitz, Riedler & Hurwitz, 1170 Broadway, New York, representatives, has been incorporated with a capital of $200,000, to manufacture paper products. The incorporators are H. and B. Kuskel, and H. L. Rosenberg.

THE WELCH JAPANNING CO., Woburn, Mass., has been incorporated with a capital of $10,000, to manufacture japanned metal products. George C. Dempsey, 133 Commonwealth Ave., Boston, is treasurer and representative; William C. Welch is president.

THE E. E. DICKINSON CO., Essex, Conn., has been incorporated with a capital of $750,000, to manufacture essential oils, extracts, etc. The incorporators are Edward E. and Edward E. Dickson, Jr., and Carl F. Anderson, all of Essex.

THE CHLOROPHEN CHEMICAL CO., Elkins, W. Va., has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are C. L. Stuckey, F. A. Ravenscraft and F. S. Johnson, all of Elkins.

THE ILLINOIS PRODUCTS CO., 1850 West North Ave., Chicago, Ill., has been organized under state laws to manufacture chemicals and kindred products. The incorporators are Frank P. Lyons and Louis Lowy.

THE POLO OIL CO., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws with a capital of $100,000, to manufacture petroleum products.

THE HAGERSTOWN LIME & CHEMICAL CO., Hagerstown, Md., has been incorporated with a capital of $30,000, to manufacture chemicals, lime and affiliated products. The incorporators are Jacob S. Myers, Enos L. Kitzmiller and William R. Moler, all of Hagerstown.

THE RUSTOFF CO., Brooklyn, N. Y., care of Bick, Godnick & Freedman, 215 Montague St., Brooklyn, representatives, has been incorporated with a capital of $100,000, to manufacture chemicals and affiliated products. The incorporators are W. Godnick, J. A. Freedman and R. Mendel.

THE REPUBLIC PAPER PRODUCTS CO., Richmond, Va., has been incorporated with a capital of $100,000, to manufacture paper specialties. A. H. Cohen is president and I. W. Cohen, secretary.

THE REED SMITH CHEMICAL CO., Camden, N. J., care of the Corporation Trust Co., 328 Market St., Camden, representative, has been incorporated with a capital of 1,000 shares of stock, no par value, to manufacture chemicals and chemical byproducts.

THE PENN PROCESS CO., INC., Philadelphia, Pa., care of Albert W. Sanson, Bailey Bldg., Philadelphia, representative, is being organized to manufacture chemicals, chemical solutions and kindred products. The company is headed by Charles W. Beck, Sr. and Jr., and Horace D. Beck.

THE FOSTER PETROLEUM PRODUCTS CO., Jamestown, N. Y., care of A. C. Nelson, Jamestown, representative, has been incorporated with a capital of $25,000, to manufacture oil specialties. The incorporators are E. S. Nelson and C. S. and A. C. Foster.

THE KEENAN PETROLEUM CO., Houston, Tex., has been incorporated with a capital of $100,000, to manufacture petroleum products. The incorporators are L. W. Keenan, C. W. Drury and R. K. Howell, all of Houston.

THE BRANFORD BROTHERS FOUNDRY, INC., Branford, Conn., has been organized under state laws to manufacture iron, steel and other metal castings. H. A. Cox is president; and Robert L. Rosenthal, treasurer, both of Branford.

THE MERIDEN INDUSTRIAL ALCOHOLS, INC., Newark, N. J., has been incorporated with a capital of $10,000, to manufacture denatured alcohol and kindred specialties. The incorporators are Jeffrey J. Lewis, Leo Roon and Morris Reiser, 321 Washington St., Newark. The last noted represents the company.

THE AMERICAN EFFECTION CORP., care of the Delaware Registration Trust Co., 900 Market St., Wilmington, Del., representative, has been incorporated under Delaware laws with capital of $500,000, to manufacture chemicals and chemical byproducts.

THE IRVINGTON ALUMINUM FOUNDRY & STOVE WORKS, INC., Irvington (Alameda County), Cal., has been incorporated with a capital of $100,000, to manufacture aluminum, iron and other metal castings. The incorporators are Thomas Tierney, P. C. Hanson and Frank A. Leal. The company is represented by E. M. Grimmer, Irvington.

THE BLAISDELL PETROLEUM PROCESS & REFINING CO., Portland, Me., has been incorporated with a capital of $200,000, to manufacture petroleum products. L. T. Garniss is president; George W. Garniss, treasurer. The company is represented by Charles J. Nichols, Portland.

THE HOUSTON OIL CO., Houston, Tex., care of the Colonial Charter Co., Ford Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws with capital of $3,000,000, to manufacture petroleum products. The incorporators are Walter F. Brown, Joseph F. Meyer, Jr., and John A. Deering, Houston.

THE HAGIN TURPENTINE CO., Lyman, Miss., has been organized under state laws to produce turpentine and kindred products. The incorporators are E. Hagin and F. R. White, both of Lyman.

Industrial Developments

GLASS — The Scott-Warman Glass Co., manufacturer of hollowware, has commenced produced at its new local plant comprising a rebuilding of the factory destroyed by fire a number of months ago. Employment is being given to about 125 men on full turn, with a scheduled output of 2 carloads of bottles per day day. The company is said to have orders on hand to insure this basis of production for a number of months to come.

Owing to a shortage of natural gas, glass plants at Salem, W. Va., have been forced to curtail operations. The Salem Co-operative Window Glass Co. and the Salem Flint Glass Co. have temporarily suspended, with prospects of resuming at an early date.

PAPER—Officials of Sears, Roebuck & Co., Arthington and Homan Aves., Chicago, Ill., have organized the Eddy Paper Co. of Illinois, to take over and operate the mills of the Eddy Paper Co., at Three Rivers and White Pigeon, Mich. The acquisition is said to have resulted from financial difficulties. The new owners plan to resume operations at the mills at an early date, having the plants on a capacity basis in about 60 days.

The Dixie Wax Paper Co., Dallas, Tex., has opened its new plant at 3008 Williams St., on a production basis of 5 tons per day. The mill is said to be the only one of its kind south of Kansas City, Mo. It is expected to maintain full operations for an indefinite period. William H. Bryce is treasurer.

RUBBER—The Interlocking Cord Tire Co., Akron, O., is planning to increase production at its mill at an early date. Additional workers will be employed.

Following the appointment of a receiver for the Perfection Tire & Rubber Co., Fort Madison, Iowa, officials of the company are developing plans for a reorganization, and expect to place the local plant on an operating basis at an early date.

LEATHER—The Armour Leather Co., Chicago, Ill., is running its side leather plant at full capacity, with regular working force, and plans to continue on this basis for an indefinite period.

The American Oak Leather Co., Cincinnati, O., has placed its plant on a basis of about 85 per cent of capacity.

CERAMIC—The Hazleton Brick Co., Hazleton, Pa., is operating on a full production basis at its local plant, and will probably continue on this basis throughout the winter.

Operative potters at Trenton, N. J., out on strike for a number of weeks, have appointed a conference committee to negotiate for a settlement with the local sanitary ware plants. It is said that other local organizations in the different pottery centers will take similar action. A number of the potteries at Trenton have discontinued operations and are installing casting plants to eliminate a considerable number of workers heretofore necessary.

Brick-manufacturing plants in the Chicago, Ill., district, equipped with mechanical drier plants, are continuing operations at full capacity under a heavy demand for material. It is expected to continue without interruption for a number of months to come.

IRON AND STEEL—The Inland Steel Co., Chicago, Ill., has 3 blast furnaces in operation, and is running 15 out of 18 sheet mills.

The Scottdale Furnace, Scottdale, Pa., has been placed in blast following a shut-down of more than 2 years. The furnace has a capacity of 350 tons of pig iron per day, and will give employment to a working force of 250 men.

The Michigan Steel Corp., 1706 First National Bank Bldg., Detroit, Mich., recently organized with a capital of $1,000,000, is perfecting plans for the construction of a new mill on site comprising about 35 acres of land between Oakwood and Ecorse, Mich., lately acquired. The initial works will comprise six units, with power plant and other mechanical buildings, and is estimated to cost in excess of $600,000. It is expected to be ready for service in the fall of 1923, and will give employment to about 400 men. Initial production will be devoted to sheet steel for automobile and other important lines of manufacture. Frederick H. Lovejoy is chairman of the board; George B. Link, formerly connected with the West Penn Steel Co., is president and treasurer; and Frank R. Jones, vice-president.

The Trumbull-Cliffs Iron Co., Youngstown, O., a subsidiary of the Trumbull Steel Co., is developing record production at its new blast furnace, which has now been completed and in service for about a year [illegible], in a 24 hour period, the stack produced 867 tons of pig iron, and in a 30-day turn manufactured 22,500 tons.

The Tennessee Coal, Iron & Railroad Co., Birmingham, Ala., has blown in its No. 5 furnace at Ensley, Ala., making six stacks in production at this place. Three of the furnaces are on foundry iron, the others on basic, while the Alice furnace is producing steel-making iron.

The National Enameling & Stamping Co., Granite City, Ill., expects to have its new sheet mill, now in course of construction, ready for service some time during next July. The mill will represent an investment of close to $1,500,000, and will give employment to a large increased working force at the plant.

The Cambria Steel Co., Johnstown, Pa., has been making a number of improvements at its limestone quarries at Naginey, Pa., preparatory to increasing production. Five large steam shovels will be used for rock digging, replacing man-labor. A daily output of 28 carloads of graded limestone will be produced for use at the Johnstown steel mills. The working force will be increased in a number of departments, bringing the quota to about 200 men.

The Shelby Iron Co., Shelby, Ala., has its blast furnace out for repairs, and is making ready to blow in the stack shortly after the first of the year.

COKE—The Semet-Solvay Co., Syracuse, N. Y., has arranged for an immediate increase in production at its Riverside coke plant from 250 to 400 tons per day, to accommodate the increased demand from the local works of the National Tube Co.

The Alabama By-Products Co., Birmingham, Ala., is making ready to place its new battery of 25 coke ovens in service, giving the plant a total of 75 ovens, devoted to high-grade foundry and gas house coke.

MISCELLANEOUS — The Champion Spark Plug Co., Toledo, O., manufacturer of porcelain spark plugs, is arranging for a heavy increase in production at its plant during 1923.

Paint manufacturers in the vicinity of Cleveland, O., are operating on a full capacity, full time basis, as compared with a usual decline in this same season in other years. Paint and varnish producers at Philadelphia, Pa., are also on a capacity schedule.

The Standard Chemical Co., Denver, Colo., is discontinuing production at its Carnotite properties, Paradox Valley district, Montrose County, for an indefinite period. About 250 men will be released from the works.

The Marland Oil Co., operating in the Mid-continent field, Oklahoma, has advanced production to a basis of 18,000 bbl. of crude oil per day.

The Texas Sulphur Co., Orange, Tex., is being reorganized and plans to resume operations at its properties at an early date at close to capacity basis. Charles F. Suderman is president.

Manufacturers' Catalogs

THE COMBUSTION ENGINEERING CORP., New York, has issued two new pieces of literature. The larger bulletin, on the Coxe stoker, covers particularly the performance of this stoker on Western and mid-Western bituminous coals. A number of test reports, each accompanied by corresponding curves, are included. These tests show very remarkable results and because they are complete in every respect they will be of considerable interest to the engineering world. Three years ago it was thought impossible to burn bituminous coal on Coxe stokers or any forced draft traveling grate stokers. Today we have a number of successful installations in some of the biggest and most important plants in the Middle West. Pictures of a number of them are shown in this bulletin. The smaller bulletin, the "Service Bulletin," while it is issued by this company, will be of value to all stoker companies. At the present time it is necessary for stoker manufacturers to render, gratuitously, service of a very costly nature. This booklet presents the stoker manufacturers' side of the question and shows why a proper charge for real stoker service would not only be fair to the recipient but would be to his advantage. It is illustrated with an interesting cartoon story.

THE JEFFREY MFG. CO., Columbus, O., in Catalog 257, treats of Standardized Scraper Conveyors. Interesting illustrations and descriptive matter on these conveyors are given.

THE DAYTON-DOWD CO., Quincy, Ill., announces Bulletin 249, which supersedes Bulletin 244 on Centrifugal Pumps.

THE COOPER HEWITT ELECTRIC CO., Hoboken, N. J., has issued pamphlets on "Quartz-Glass Apparatus for Photophysics and Photochemistry," "The Ultra-Violet," "Uviarc Lamps in the Laboratory," "The Lab-Arc," and "The Uviarc Test for Dyes, Inks, Textiles, Leather, Paints and Paper."

H. S. B. W.-COCHRANE CORP., Philadelphia, discusses, in a recent pamphlet, the deaëration of water to prevent corrosion in piping, economizers and boilers. The apparatus described is designed to deliver water free of dissolved oxygen, at any temperature from 140 deg. F. up, as required for hot water heating and service systems and for feeding to economizers and boilers. The method consists in heating the water by spraying in a chamber under vacuum and then vigorously agitating or scrubbing the water by blowing steam through it. The heating of the water to the temperature corresponding to the pressure existing in the vessel renders gases insoluble, while the subsequent reboiling of the water serves to pick up and flush out small gas bubbles which otherwise would not have time to escape from the water. The Cochrane vacuum deaërating heater is designed to be used where the auxiliaries are operated under vacuum or where they are operated under back pressure, also in connection with primary and secondary heaters and as the condenser for a make-up evaporator. The full vacuum corresponding to the temperature to which the water is heated is available to the house turbine or other auxiliaries exhausting to the heater. Charts are given showing the amount of iron converted into rust by water containing different amounts of oxygen, vapor pressures, corresponding to water temperatures and solubilities of oxygen and nitrogen in water at various temperatures and pressures. The Winkler test for detecting dissolved oxygen in water is also described.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold a meeting Dec. 26 to 30 in Boston, Mass.

AMERICAN CERAMIC SOCIETY will hold its annual meeting in Pittsburgh, Pa., Feb. 12 to 17, 1923.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting April 3 to 7, 1923, at New Haven, Conn.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting May 3, 4 and 5, 1923, at the Commodore Hotel, New York City.

AMERICAN ENGINEERING COUNCIL, executive organ of the Federated American Engineering Societies, will meet in Washington, D. C., Jan. 11 and 12, 1913.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its annual meeting in New York City during the week of Feb. 19, 1923.

INTERNATIONAL CHAMBER OF COMMERCE will hold its second general meeting in Rome, Italy, March 19-26, 1923.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF CHEMICAL INDUSTRY, American Section, will meet in Rumford Hall, 52 East 41st St., New York City, on Dec. 15.

SOCIETY OF INDUSTRIAL ENGINEERS, with headquarters in Chicago, will hold its spring convention in Cincinnati, April 18, 19 and 20, 1923. The major subject will be "Management Problems of the Smaller Plants."

TECHICAL PHOTOGRAPHIC AND MICROSCOPICAL SOCIETY will hold a meeting with the Society of Chemical Industry, Dec. 15, at the Chemists' Club, East 41st St., New York City.

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, East 41st St., New York City; Jan. 5 — American Chemical Society, regular meeting. Jan. 12—Society of Chemical Industry, Perkin Medal. Feb. 9—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting. March 9—American Chemical Society, Nichols Medal. March 23—Society of Chemical Industry, regular meeting. April 20—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting. May 4—American Chemical Society, regular meeting. May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting. May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.

Some Light on The Arsenic Situation

TEN YEARS AGO arsenic was the yellow dog of every copper and lead smelter, the undesirable citizen in every smelting community. Today it has suddenly assumed the important rôle of the public benefactor. Without its use in the form of calcium arsenate the cotton farmer is practically defenseless against the ravages of an insect pest that has already left a trail of ruthless devastation.

But it is just this sudden change from yellow dog to benefactor that has played havoc with the arsenic market. A demand exists for which there is little hope of adequate supply. Confronted by this serious shortage and with speculation carrying prices to dizzy heights, it has been increasingly evident that the time was ripe for the industry to stop and take stock of the situation, weighing carefully the different factors and influences involved. Such a step was taken in a recent conference in New York, chronicled on the news and market pages of this issue.

The value of this meeting to the industries concerned and to the public as well can, perhaps, best be measured in terms of the new light shed on the arsenic situation. At least four things were accomplished that were decidedly worth while: First, the stocks on hand, trade requirements, productive capacity and foreign supply were accurately evaluated. Next was the quantitative view of the country's needs for calcium arsenate supplemented by Dr. COAD'S keen analysis and impartial portrayal of the economic status of the cotton farmer. The third accomplishment was the recognition by both producer and user of the need for a stabilized market. The last and in a way the most important finding was the welcome discovery that the current frenzy of speculation is not a serious factor in the situation, primarily because the quantities involved are probably of negligible proportions. In one case it was reported on good authority that a single 25-ton lot of white arsenic had actually been known to change hands as many as six times during a single day.

The Geological Survey is authority for the statement that stocks of domestic arsenic on Oct. 1 totaled but 1,230 tons and that 3,400 additional tons would be produced by May 1, 1923. If to this is added the 900 tons of imported material that has not yet passed into consumption and the 600 or 800 tons that may be expected from abroad, it will be found that the total falls short by at least 2,000 tons of the 8,450 tons estimated as the requirement of the trades other than calcium arsenate manufacture. Just how much arsenate the cotton grower actually needs was set forth so clearly by Dr. COAD, of the Department of Agriculture, that little doubt could be left as to the seriousness of the situation. Moreover, he sounded a note of warning to both the arsenic producer and the insecticide manufacturer who may disregard the farmer's ability to pay and his expectation of a return on his investment. The government's estimate that three times as much calcium arsenate will be consumed in 1923 as in 1922 is predicated on the assumption that the price will not prevent its use with profit on lands yielding but half a bale of cotton per acre.

The producers' appeal for stabilization requires but little elaboration here. One need only mark the peaks and valleys in the arsenic price curve to realize the hazards such a market has for the producer. And too often for comfort the insecticide manufacturer has found himself buying arsenic at top prices and forced to sell his arsenate after the bottom of the market has dropped completely out. He too is interested in lopping off the peaks and filling in the valleys.

These facts, together with the severe blow dealt to speculation and resale, are some of the accomplishments that have come out of this brief conference of arsenic producers and consumers. In the future we may well expect co-operation to be the keynote of further business progress, and even greater results may be expected when maker and user, buyer and seller, meet on a common ground for sober study of their mutual problems.

Approval From Germany

OF DOUBTFUL compliment to American chemical industry is the comment appearing in a recent issue of *Die Chemische Industrie* relative to our editorial criticism of the Allied Chemical & Dye Corporation, published recently under the caption "Looking a Gift Horse in the Mouth." It will be recalled that we referred to the corporation's policy of wholesale dismissal of technical men and the assumption of leadership by EUGENE MEYER and ORLANDO WEBER, whose financial interests are well known to overshadow their knowledge of chemistry or pride in the industry.

After publishing our editorial in full, our German contemporary closes with a comment by the translator, of which the following is a free version:

> In the interest of our German chemical industry it is to be hoped that the affairs of the Allied Chemical & Dye Corporation shall continue to be directed by the above-named gentlemen, one of whom is a Wall Street speculator, while the other gained his experience as an "efficiency expert" in the automobile industry. Against the consequences of such mismanagement it will soon become evident that even the new high protective tariff cannot prevail.

Die Chemische Industrie is the official organ of the Society for the Protection of the German Chemical Industry, and while its approval of American conditions is not particularly welcome in this instance, it coincides with the conclusion that has been reached in some quarters at home.

Hands Off For Two Years

DESPITE the marked increase in salaries granted a year ago, the Patent Office is still having difficulty in getting and retaining first-class examiners. The seriousness of the situation is shown in the fact that twenty-two examiners left the Patent Office during last August and September. But even before that exodus began there were seventeen vacancies on the staff. Inasmuch as the Commissioner of Patents holds that it requires two men during their first year of service to do the work of one experienced examiner, it will be apparent that this deficiency of thirty-nine indicates a need for seventy or eighty new men in order to put the staff on a suitable working basis.

It may be argued that this problem and its solution is wholly for government consideration; but there are responsibilities outside the Patent Office that cannot be dodged. There has been altogether too great a raid on the Patent Office staff during the past few years. Recognizing its own responsibility in this matter, the American Patent Law Association has just taken a step that should be of material help. The managing board of that body has written a vigorous letter to its members urging that for at least two years they refrain from hiring members of the Patent Office staff. Thus the association hopes to create a two-year closed season, during which the Patent Office can recruit its personnel and bring its work more nearly up to date.

Industry should follow this excellent example, for there is no greater sufferer from an inferior or inadequate staff in the Patent Office. The cost of contesting a single patent case consequent upon the faulty work of an inexperienced or overworked examiner may easily exceed the total cost of maintaining the patent department of a corporation. It will be profitable, therefore, even selfish, for industry to encourage the Patent Office in recruiting a normal staff and bringing its work up to date. To this end industrial corporations should join with the American Patent Law Association in keeping hands off the Patent Office staff for at least two years.

Support the National Exposition Of Chemical Industries in 1923

DISCUSSION and controversy regarding the chemical exposition have not been allowed to lag, due largely to the activities of those who have been promoting the idea of a co-operative organization. Also a committee of the Salesmen's Association of the American Chemical Industry has been active with inquiries and questionnaires in an effort to ascertain the desires of past and prospective exhibitors. The results thus far obtained are rather intangible, although more definite information may appear when the committee finishes its work.

The plan for a co-operative show has lost ground, if we may judge from a circular from ADRIAAN NAGELVOORT under date of Dec. 7. After analyzing the situation as he now sees it and still clinging firmly to his contention that a co-operative exposition "offers the ideal medium" for bringing all the elements of our chemical industry together, he concludes that "the concurrence of opinion of exhibitors and of the industry generally is for the abandonment of both shows for 1923." Not only do we differ with this opinion but we consider it an unfair statement. The campaign for a co-operative show has failed, at least for 1923, but it is unfair to infer that the National Exposition has met or should meet the same fate. As a matter of fact, we are reliably informed that 154 exhibitors have signed contracts for space in the Ninth National Exposition of Chemical Industries and that this is the largest number of contracts ever signed at a corresponding date previous to any former exposition. Whatever may be the ultimate fate of the chemical exposition with respect to annual or biennial, co-operative or non-co-operative shows, we consider it in the best interests of the industry as a whole to proceed with the Ninth National Exposition of Chemical Industries now scheduled for September, 1923.

Historical Perspective, The Father of Invention

WHY is it that we have made such great advances in the mechanical arts and in natural science during the past hundred years? Substantially all of our progress and marked improvements have been within these fields. In the arts of living, in politics, in government, in law and in the graces of life we have made very little if any progress. It is evident, however, that the last few generations of men have greater mental energy in the application of science and mechanical arts. Our forefathers were much more severely put to it to invent mechanical strategems than is the farmer of today.

Necessity is indeed the mother of invention, and the need has always been pressing. If we would seek the father of it, we believe he may be found in the historical perspective offered by patent office reports, the records in scientific journals and the transactions of learned societies. Only in these respects do we find successfully accomplished what KORZYBSKI calls "time-binding" elements. The records of living men are thus made permanent; and as they pass on others build improvements upon the contributions of the dead, so that, viewed as a whole, the record is a continuous one. The literature may be awkward; and the search may be difficult, but it can be done and it is done constantly. There is no such history of law; we have merely a protocol of decisions. Neither can we find such a history of anything else than science and the mechanical arts. We venture the opinion that historical perspective is the father of invention.

The Utility of Historical Chemistry

IN CHEMISTRY, as we go about among men who are true masters, we observe that usually their scientific scholarship carries them beyond the patent office reports and the files of the journals into the still unpublished and uncorrelated history of the science. An old chemist was lately addressing a group of his fellows composed principally of members of the staff of one of the great industrial establishments of this country. The corporation is fortunate in the knowledge that its men of science are fellow officers with its business administrators and sales directors in the struggle for progress. They are not common soldiers. A remarkable *esprit de corps* obtains in the laboratories, works and groups of officers. Everybody believes in the organization and has faith in it. Men who are ignorant of what chemistry means have not been invited to command. As a natural sequence to this, the type of chemists on its staff is of a high order. They are getting results, and there follow those intensive but unhurried habits of success that are its pleasant accompaniment.

The old chemist introduced into his talk a number

of incidents taken from the byways of chemical history, incidents that are not outstanding in the textbooks. He was graciously received and generously applauded, but he had, somehow, the feeling that he had been repeating that which was not new to most of his audience and intimating trains of thought that they had already considered for themselves. He was right. The pleasure of work in a sympathetic atmosphere had brought there a body of men who sense their science in the large, and who do not take it as a trade or a craft. If a chemist really loves his subject he wants to know all that he can about it, and this usually leads him also into the more remote but still living work of those who have long been dead. History gives us the perspective that the best of us need.

Railroad Service And Earnings

FEW of the industrial activities of the country are reported upon so fully and precisely as are the operations of the railroads, yet the general public is very poorly informed as to the actual facts. This curious and unfortunate condition arises from the circumstance that many groups of interested parties talk about the railroads and railroad conditions, each with personal motives. The object is not to inform the public but to argue for some private end. Those whose business it is to sell railroad material assert that the railroads are poorly equipped and ought to be put in position to spend a great deal more money. To support the argument they sometimes magnify the shortcomings of the roads in the rendering of service to the public. The salaried spokesmen of railroad employees, seeking high wage rates, often claim that the railroads are run extravagantly, wasting much money that could easily be diverted to payrolls. Salesmen of various classes of goods talk of car shortage and prospective traffic congestion as an argument why their goods should be bought promptly and stiff prices paid. Coal operators, members of "the badly functioning industry," endeavor to divert the public mind to the railroads as a great cause of the coal trouble because they do not keep large supplies of cars on tap. Many men who sought and obtained election or re-election to Congress attacked both the railroads and the transportation act, some asserting, for instance, that the act "guarantees" railroad earnings, when the one thing it does on that head is to limit disbursements to stockholders if earnings chance to be made.

In the circumstances the public cannot be expected to be correctly informed, nor is it reasonable to expect the general public to take pains to inform itself. The information is available, but it is voluminous and complicated. The public may think that those who talk about railroads and railroad conditions are giving information, but even if concrete facts are stated with technical accuracy, which frequently is not the case, the perspective is usually greatly distorted.

Insufficiency of railroad service in the past 3 months has been dilated upon particularly in reports of commodity markets, whereas the railroads have done a remarkable thing in getting along so well in the very unusual conditions of a 5-month coal strike ending and leaving demand for the movement of an unreasonable quantity of coal.

The railroads have been carrying a much greater volume of freight than before the war and have performed the service with proportionately less equipment, although burdened with employment regulations that did not formerly exist. The railroads are expected to provide themselves with facilities to carry peak loads when they are not permitted to make the charges that other industries having peak loads require. They are expected, in not a few quarters, to carry all coal offered when the time lost in a long strike is to be made up, to move the great bulk of the crops shortly after they are harvested and to pass through lean years somehow. Railroad charges are supposed to be such that 5¾ per cent on investment shall be earned, but the railroads do not obtain the earnings, while if a road makes more than 6 per cent in a year it is permitted to disburse only 6 per cent at the time.

As the value of money goes the limit is too low, yet the present outlook, politically speaking, is that if the transportation act is modified it will be in a direction unfavorable to the railroads. Wholesale bankruptcy of the railroads would mean government operation or ownership, which the public does not want. If this result is to be avoided, it seems imperative that the public be better informed by an impartial agency.

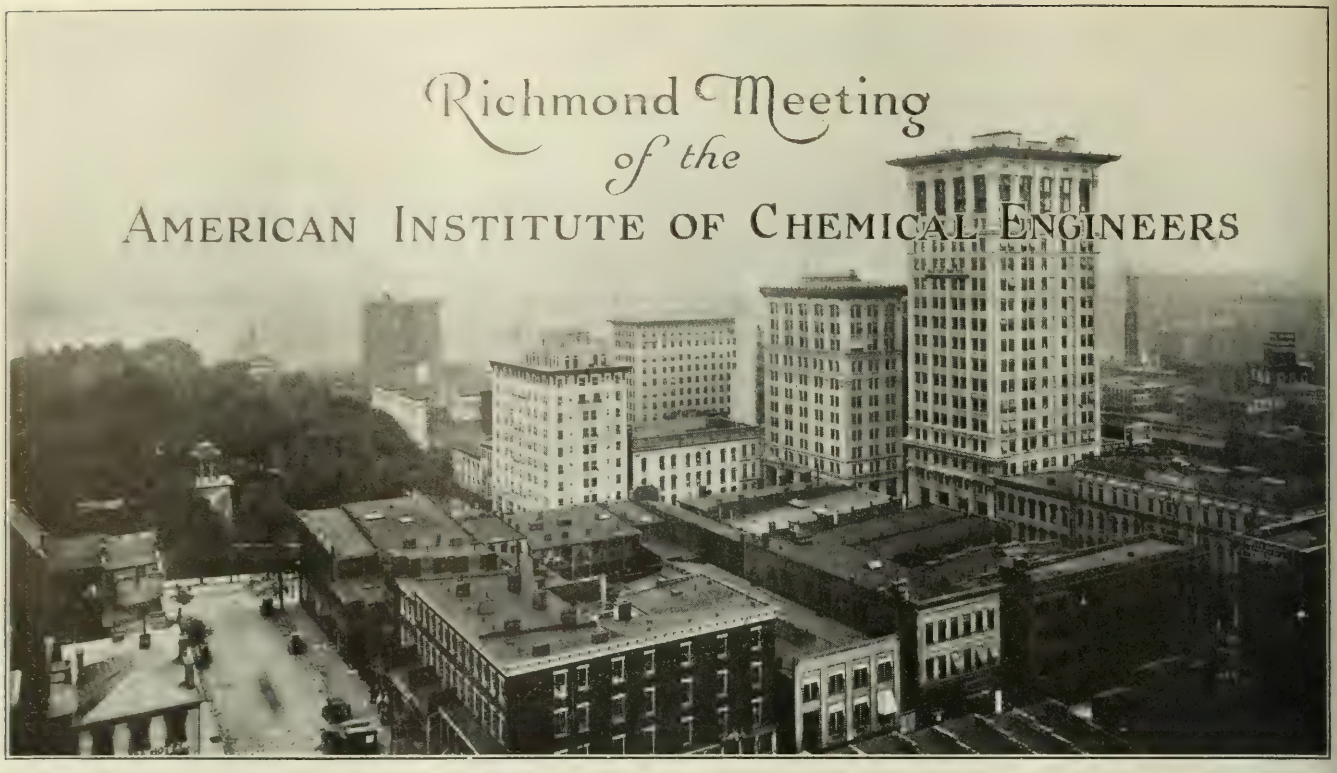
Efficiency Rampant

IN A formidable document of 400 pages the U. S. Bureau of Efficiency has just issued a "Report on the Statistical Work of the U. S. Government." Perhaps a useful purpose has been served in compiling and bringing together within the covers of one book a list of the varieties of statistical information collected and disseminated by the government; but the conclusions and recommendations of the bureau approach a degree of absurdity. It seems inevitable that inefficiency would result from the adoption of the bureau's ideas.

The statistical output of the government is grouped in this report under twenty-seven headings and the bureau undertakes to show that there is a great deal of duplication of effort and overlapping of work among the various statistical gathering departments. In the name of efficiency it is proposed to centralize this work, now conducted in over forty government bureaus.

In judging efficiency it is quite as important to measure the quality of the product as to measure the quantity. Sometimes quantity production can be achieved only at the expense and sacrifice of quality. The usual consequence is that the product is worthless in those cases demanding a superior grade of article. Doubtless this would hold true in the case of government statistical work, for a centralized and glorified statistical bureau would undoubtedly produce quantities of figures without much regard to their usefulness or significance.

Anyone who has used government statistics knows the particular value of those data furnished by bureaus that are essentially technical in their character. These figures are not only reliable and generally acceptable; they are also intelligently prepared and intelligibly presented. Their interpretation and application in science, industry or commerce is quite clear and easily accomplished. On the other hand, a different situation is found in those government offices that deal with statistics alone without a knowledge of the industry, the commodity or the business to which the data relate. Gathered and handled in a mechanical, perfunctory manner, the results are of doubtful accuracy and of uncertain significance. In our judgment any step that would consolidate the statistical work of the government would rob the best of it of its present value and tend to standardize downward toward mediocrity.



The Feature of the Technical Program Was a Symposium on Materials of Construction, Covering Wood, Stoneware, Tantalum, Magnesium Oxychloride and Glass—Interesting Industrial Excursions, Including War-Time City of Hopewell—Election of Officers and Transaction of Other Business

EDITORIAL STAFF REPORT

THE fifteenth annual meeting of the American Institute of Chemical Engineers was held in Richmond, Va., beginning Wednesday, Dec. 6, and extending through Saturday, Dec. 9. The feature of the meeting from the point of view of technical papers was a symposium on the materials of construction in chemical plants. A number of important papers were presented, some making a thoughtful review of the use of well-known materials such as wood and portland cement, others discussing materials comparatively novel, such as magnesium oxychloride cement and asbestos protected metal. An extremely dramatic paper from the point of view of the technical man was that presented by A. E. Marshall of Baltimore on the use of Pyrex glass as an engineering material. The other features of the meeting included visits to some of the large tobacco plants for which Richmond is extremely well known and of which industry it is the national center, and a visit to the city of Hopewell, the seat of the famous explosive plant of the du Pont company during the war.

It has become almost proverbial in reporting meetings to pass a bouquet to the local committee, and the Institute has been peculiarly fortunate in being entertained by exceptionally able local committees. In this case an especial palm is perhaps in order, because there were no members of the Institute on the local committee. The successful completion of a very attractive program was greatly appreciated by the members and guests and the rising vote of thanks which was given to the members of the local committee expressed very inadequately the gratitude of the convention. J. G. Armistead, the local chairman; Mr. Dabney, of the Richmond Chamber of Commerce; Dr. Ryland, of Richmond University, and Mr. Rudd are some of the men who will always be remembered by the Institute for the very enjoyable Richmond meeting.

Business Meetings

IMPORTANT CHANGE IN PUBLICATION POLICY

Some questions of fundamental policy were discussed and decided during the business session. One of the most far reaching had to do with the date on which manuscripts must be forwarded to the secretary in order to be included in the program of a meeting. This is far reaching because, in setting the date 60 days in advance of the meeting, a positive censorship is created and time given sufficient for the preparation of preprints. The committee felt that the policy of sending preprints was a good one, inasmuch as a free discussion of the papers would thus be very much encouraged. Finally, submitting the papers 60 days in advance of the meeting will facilitate the publication of transactions of the society by compelling authors to be prompt with their manuscripts. There was some objection on the ground that some papers would never be available for the Institute, but it was felt that the committee would use its discretion if such a situation presented itself.

ELECTION OF OFFICERS

President Henry Howard was re-elected for the year 1923, and the other officers were returned to office without contest as follows: First vice-president, A. W. Smith; second vice-president, H. K. Moore; third vice-president, H. S. Miner; secretary, J. C. Olsen; treasurer, F. W. Frerichs; auditor, C. F. McKenna. Prof. Edward Bartow of Iowa, Prof. R. H. McKee of Columbia and J. V. N. Dorr of New York City were elected to the council for three years. Reports from the secre-

tary and the treasurer indicated a healthy growth in membership and a financial condition which warranted a reduction in the annual dues to $18 for senior members and $12 for junior members.

A number of committees reported at the meeting in addition to the committee on publications, the report of which has been already referred to. The committee on evaporator test code, working in conjunction with the committee from the Society of Mechanical Engineers, reported progress. The committee on patents reported informally through letter that it was in accord with President Howard's efforts to insert a working clause in the Stanley bill. President Howard announced that the bill was a dead issue for this session of Congress, but that it would be in order for the Institute committee to act with other organizations when the bill comes up for consideration.

The new committee on chemical engineering education held its first meeting, which was reported successful. Plans were laid for carrying on this important work. A tentative weighting of general subjects in chemical engineering courses was adopted and it is one of the functions of the committee to endeavor to bring about a more even balance in the curricula of institutions offering chemical engineering.

A resolution instituted by the committee on licensing engineers was passed which reiterated the position already taken by the Institute that it did not favor the licensing of engineers and that it would use its influence and work for a repeal of present and existing legislation.

Social Features and Plant Visits

Richmond and its vicinity represent two things, a modern American community, aggressive, bustling, human, and a shrine of Confederate memories. Recall that Petersburg, only 15 miles from Richmond, was practically the last stand of the Confederacy, for when it fell Richmond and Appomattox were bound to follow. In addition Richmond was the capital of the Confederacy and therefore the Institute trips would naturally reflect both of these phases of Richmond. On the one hand, the tobacco industry, of which Richmond is the center, the home works of the largest fertilizing company in the world, the largest cedar plant in the world, and on the other hand Battle Abbey, the trenches around Petersburg where the Confederates held the Federals at bay for many weary months, the famous

THE HOUSE OF AMERICA'S GREATEST JURIST, JOHN MARSHALL

BLANDFORD CHAPEL

A Confederate shrine now, containing the beautiful Tiffany windows in memory of the soldiers of the South who fell in defense of Petersburg.

crater blown up by the Northern troops in an effort to pierce the Confederate lines and a hundred more historical relics of a similar kind.

Tobacco Industry

T. M. Carrington, president of the Tobacco Association of the United States, paved the way for an intelligent inspection of the tobacco factories with a very instructive address on the American tobacco industry. The figures were somewhat amazing as to the extent of the industry and the value of its products. More than $1,600,000,000 is spent annually for tobacco in the United States. Last year there was produced 60,000,000,000 cigarettes, 8,000,000,000 cigars and 275,000,000 lb. of tobacco. Mr. Carrington went on to develop the elaborate steps which are necessary in the growing and curing of tobacco. The tobacco plant seems to have more enemies than almost any other known plant, for a veritable army of worms and insects are intent on destroying it in some way or other. It is first sprouted on a carefully prepared field under canvas to protect the young plant from heavy rains and heavy sun, and when finally matured it is dried out in barns and finally aged in casks of oak.

So when at the start of the tour through the tobacco factory one sees the workmen removing the dried leaves from heavy casks the reason and history are somewhat more comprehensible. The leaves are first steamed and then dipped into a solution which contains licorice and sugar and a number of other things which go to make up the tobacco formula. The leaves thus impregnated are then squeezed to remove the excess liquid and dried at a relatively low temperature. The next step consists in forming pressed cakes of tobacco in hydraulic presses, after which the cakes are cut as desired. Perhaps the most interesting thing in a smoking tobacco factory is the automatic machinery for packing the material into tins or cartons as well as the manual dexterity of the girls who are handling tobacco which cannot be packed automatically.

In the cigar factory the preparation of the filler and the final wrapping are both carried out on automatic machines. In each case the only hand labor necessary is the placing of the leaf wrapper on the cutting die. The final wrapping machine is most ingenious, as it cuts the wrapper to the desired shape, picks it up and rolls it onto the filler, which has in turn already been placed in position automatically. The machine then takes the cigar to a rotating thimble, which seals the ends of

it and in the meantime the other end has been clipped off even. The only hand labor connected with the operation is, as has been said before, setting the filler on the cutting die and picking up the finished cigar for final packing.

The Hopewell Excursion

Hopewell has always been a name by which the chemical engineer conjures, for during the early part of the war period it sprang into being in almost unbelievably short time as an explosive plant of the du Pont company. At its height of construction and operation there were over 30,000 people in Hopewell. Shortly after the armistice, however, the town dwindled until barely 3,000 were left. Since then also a surprisingly large percentage of the equipment placed there during the war by the du Pont organization has been liquidated and there are many acres on which nothing remains except concrete piers and brick foundations where formerly acid and explosive units were in full operation.

The Institute arrived somewhat later than was expected and was able to inspect only the Hummel-Ross pulp factory. An interesting feature of this plant is the use of a large deposit of niter cake which was left by the du Pont company in a valley near by. A fiber company has bought up a large percentage of material and it is expected that it will last for a good many years. Other industries which exist at Hopewell are the Tubise Silk Mills, manufacturing silk by a Belgian process from wood; bag and trunk manufacturers, the Stamsocott Paper Co., the Hopewell Chemical Co. and a number of others. At the present time the town has grown substantially and consistently until now there are over 9,000 inhabitants. The site was well selected by the du Pont company, inasmuch as it offers the facilities of water transportation, relatively cheap fuel and a substantial supply of labor of all kinds from the surrounding country.

On the way back from Hopewell a stop was made first at the famous Blandford memorial chapel, which has been set aside in memory of the Confederate soldiers who fell in the defense of Petersburg. Each Confederate state has contributed a beautiful memorial window. In its peaceful setting, with the beautiful hills around it and the old brick walls of the cemetery acting as a frame, it makes a very moving appeal.

Another stop was made at the crater, and here an old Confederate veteran described the details of that memorable and unsuccessful attempt to pierce the Confederate defense. It was up to that time and until the world war the largest explosion in warfare, many thousand pounds of powder being used to make the breach.

GENERAL ROBERT E. LEE IS A NAME OF WHICH EVERY AMERICAN IS JUSTLY PROUD

BUYING TOBACCO IS THE MOST IMPORTANT STEP IN SUCCESSFUL MANUFACTURE

Other Industries Visited

A large delegation from the Institute visited the Virginia-Carolina Chemical Co.'s plan on the outskirts of Richmond, where they make sulphuric acid, acid phosphate and mixed fertilizers. It is scarcely a typical fertilizer plant, for the building and equipment in which the acid phosphate is made and the fertilizers are mixed are very modern, but it afforded a splendid opportunity to study modern methods of manufacture in the fertilizer industry. The flow of raw materials has been carefully worked out so that the handling of materials is reduced to a minimum. The acid phosphate is manufactured in one end of the building, then come the aging pits, the mixing apparatus in which the prime mixes or so-called fertilizer bases are made. Then the storage of acid phosphate and bases, and finally the mills for mixing the finished fertilizer. Transportation is carried out on elevated track by means of an electric engine and also by means of electric cranes on either side of the center of the building.

After this an inspection was made of the Richmond Cedar Works, which is the largest cedar works in the world. Here the sawmill was a source of great interest, on which cedar logs were cut up into lumber at the rate of forty or fifty logs an hour by common laborers. In the mill itself the cylindrical saws used for cutting out the staves for buckets and pails were interesting, as well as the galvanizing pit for the metal parts on the products.

The Institute was fortunate also in seeing the Richmond Car Works, the Standard Blotting Paper Co., a baking powder plant of the Southern Manufacturing Co. and the Cheek-Neal coffee plant.

Social Functions

Before taking up the technical papers it is most appropriate that the reception and banquet be mentioned. The reception was held on Wednesday evening after the first sessions of the Institute and an opportunity was given to meet the hosts and hostesses. At the banquet the Institute had a rare treat in the shape of an address by Arthur Glasgow, consulting engineer for the City Gas Works in London, England. Mr. Glasgow was originally a Richmond boy and spoke to the Institute both as a host and as a distinguished guest. His analysis of the industrial ills from which England has suffered was very keen and he discussed the unemployment problem very frankly. He had severe condemna-

THE FAMOUS CRATER
The breach blown in the Confederate defense around Petersburg by a Union mine. The attack was a failure.

tion for the Lloyd George government because of the payment of the unemployed. This, he said, was not even a palliative for the suffering, but merely intensified the tragedy.

The only solution to the present depression is the adoption universally of the slogan, "Work and Save." Only by such means can British industry pull itself from the strangling depression which the labor unions have caused. The killing of industrial initiative by compulsion has proved disastrous. As an example Mr. Glasgow says that 300 bricks per day were all that the British bricklayers were permitted to lay, whereas an average bricklayer could easily lay 1,500 bricks. This he said was typical of the mistaken policy followed by the unions of attempting to create enough work for everybody by limiting the amount any one was permitted to do. Such limitation is the very source of a disgruntled attitude. Only by working and by working hard can there be any joy in achievement. Only by production, by work and by saving can the British workmen emerge as satisfied, wholesome citizens from their present predicament. It is a lesson which American manufacturers and labor leaders cannot afford to miss.

Technical Papers

Symposium on Materials of Construction

The program of papers included a symposium on materials of construction. Some of these papers will appear in *Chem. & Met.* In this week's issue is the paper presented by Percy C. Kingsbury, on Chemical Stoneware. Dr. C. W. Balke's article on Ductile Tantalum, F. C. Zeisberg's on Glass Rings for Tower Packing, and The Industrial Use of Pyrex Glass, by A. E. Marshall, will all be printed within the coming weeks. In addition the excellent paper by Dr. J. H. Young on Asbestos Protected Metal, which deals with the interesting development of this commodity, has been promised for an early issue. The remaining papers presented in the course of this symposium are abstracted below.

The Use of Wood in Chemical Manufacturing

J. V. N. Dorr presented a thoughtful paper on the various uses of wood in chemical industries. The advantages of low initial cost, easy replaceability, low heat conductivity (under certain conditions this property is invaluable) are balanced on the other hand by the low mechanical strength and the consequently cumbersome apparatus which results, the flammability and the fact that the tanks must be kept in use else they dry out, permitting considerable leakage. The uses of wood under various conditions were discussed and the various kinds of apparatus, including wooden pipe, both stave and hollow, centrifugal and piston pumps, etc., were mentioned. Protected wood was also discussed, as for example the lead-lined equipment and hard rubber lining. Concrete-lined wooden tanks are also in use and a large number of impregnated materials were recorded as being desirable for a number of reasons, largely for their resistance to weathering.

In the Dorr equipment wood has had a number of uses. In the case of alum plants where three agitating tanks are used lead-lined tanks are specified on top of merchantable fir. The first two washing thickeners are also lead lined but the last one is usually of fir, sometimes even the second. In the case of phosphoric acid the agitating tanks are made of clear fir, and the mechanism, arms, shaft, etc., are also made of fir. The first thickener is fir, lead lined, but the succeeding ones are of clear fir. White oak wooden barrels for acetic acid centrifuged from aspirin powders, yellow pine cooling chambers in the purification of salicylic acid by sublimation, and a few other special items were mentioned.

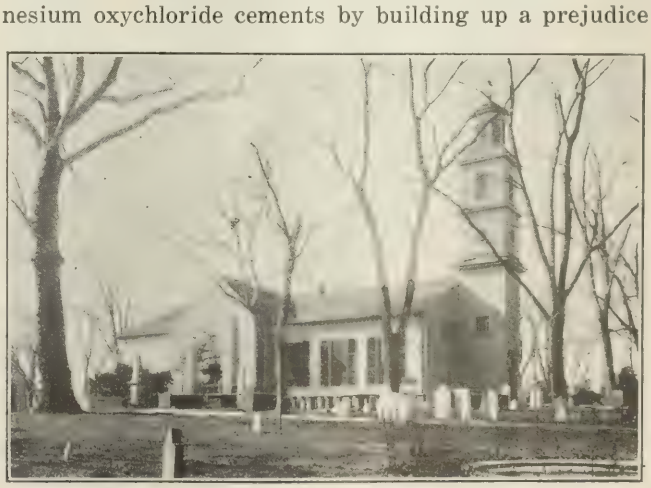
The discussion brought out the use of wooden filter presses for a number of different purposes, and further comments on the various uses of wood.

Magnesium Oxychloride Cement

A compound relatively unfamiliar to most chemical engineers was discussed by M. Y. Seaton under the general subject of magnesium oxychloride cement. It seems that this industry is comparatively young, although the cements have been known for some time. No scientific data had been accumulated in the early days of its use and it was most difficult to apply and somewhat unprofitable because of the uneven results obtained. The magnesium oxychloride cements bind woody fibers into floors and walls and a number of other surfaces and structures. One characteristic of these cements is that there is very high tensile strength at an early stage and the subsequent evaporation of water is permitted quite freely without injuring the cement. Another point of advantage is that the volume contraction is relatively low, as compared with other cements.

Some doubt exists as to whether the cement is a chemical compound or a solid solution. Probably there is a chemical compound present, $3MgO.MgCl_2.10H_2O$, but a good deal of the material is in solid solution, which gives the product its high tensile strength.

A fact which has militated against the use of magnesium oxychloride cements by building up a prejudice



HISTORIC OLD ST. JOHN'S

against them is the fact that they are decomposed by water to form magnesium hydroxide. This, however, is actually not deleterious, because hydrolysis changes the oxychloride into brucite-like hydrates. Brucite is a form of magnesium hydroxide which has very great stability and adds strength to the cement rather than weakening it.

Previous to 1914 all of the magnesium oxide used in this country was obtained by calcining magnesium carbonate, which was largely obtained in Greece. The war cut off this supply and the open-hearth steel furnaces demanded large amounts of dead-burned magnesite. This led to the exploitation of the California and Washington fields for these purposes, and this fact gave a home source of raw material for the magnesium oxychloride. As is the case with most cements, the chemical analysis is relatively unimportant. It is necessary to have plastic magnesium oxide in order to make the cement, and for white cement it is essential that it be iron free. Calcination therefore must be controlled within narrow limits of temperature. The ore must have been previously sized to within narrow limits. Practically all the burning is done on a rotary kiln at about 1,100 degrees. The magnesium oxide thus produced is then ground up in burr mills of the old fashioned variety so that 85 per cent of it will pass through 200 mesh.

This is then ready for preparation of the cement, and magnesium chloride is one of the other ingredients. This was originally found in the Stassfurt deposits, but recently it has been obtained from the sea water and brine bitterns in this country. However, these bitterns were worked over only at a time when potash was in demand from domestic sources, and as this time is past, all of the magnesium chloride is extracted from the Michigan brines.

One other interesting point about the magnesium oxychloride cement is that it is essential to supply premixed aggregates at the point of consumption. Unlike portland cement, the addition of excess cement does not make up for errors in mixing and it is therefore of vital necessity that the manufacturers put out a ready mixed product to obtain consistent results.

The Use of Concrete in Chemical Industries

A. C. Erwin, of the Portland Cement Association, presented a detailed and instructive paper on the use of concrete. Mr. Erwin emphasized especially the desirability of using less water in a mixture when making concrete from the cement and aggregate and much more water during the process of setting. This, he said, was his main message in the use of concrete not only in chemical industries but in all industries. The laboratory of the Portland Cement Association has established beyond a doubt the desirability of using less water in the mix. This is very difficult to apply in the field, because the material flows much better if it is soupy. Nevertheless, Mr. Erwin felt that too strenuous efforts could not be made toward the utilization of drier mixes in the field. Another point which he emphasized was the fact that inevitably a thin mixture will separate out in the molds—that is, the heavy aggregate will fall to the bottom and leave a top layer of much purer cement. Thus it becomes necessary to have much heavier construction than would otherwise be needed if even results were obtained by the use of the dry mix. Similarly the author pointed out the desirability of constant wetting during the first 10 days after the cement is laid.

THE WHITE HOUSE OF THE CONFEDERACY

Many other details in the use of cement were outlined and emphasized, but most of them were in accord with usual practice and need no special emphasis in this abstract. Finally, the cement gun was discussed. This is a machine which shoots a mixture of sand and cement by means of compressed air with considerable force on to a building. The water is injected into the mixture at the nozzle of the gun in an exact proportion so that the result is a mixture of concrete applied to a wall with very great force. Several of the engineers present confirmed the flexibility and satisfaction given by this machine and it was further pointed out that methods of application had improved so that the earlier results, uneven and somewhat unsatisfactory, had been completely eliminated by the improvement in the process of application. In addition, the cement gun, or gunite, as the product is called, can be used in lining tanks with cement very satisfactorily.

The Integral Waterproofing of Concrete

Prof. A. H. White, of Michigan, summarized some results of evperiments which he had made extending over a period of 10 years with waterproofing for concrete. The cry of the cement manufacturers has always been that waterproofings were unnecessary if cement was properly made. This, Professor White felt, was somewhat incorrect and from the very nature of things could not be expected to be the case. Concrete is impervious to water, nevertheless water goes through it by colloidal action and no matter how correctly the cement is mixed that colloidal action will take place inevitably. For this reason such materials as hydrated lime and clay, which are recommended as fillers, ought to have actually no effect on making the concrete more waterproof, because they are both colloids and they expand and contract as concrete does. Several other types of waterproofing compounds have been suggested. One is a water repellent type, such as asphalt, and the other is material such as soap, calcium oleate, etc. Professor White's experiments on ordinary and waterproof concrete blocks of various types consisted in studying the rapidity with which water was absorbed by the blocks and the rapidity with which the water rose due to the capillary action. Calcium hydroxide was found to give calcium carbonate after the solution had evaporated, and this seems to produce a waterproof surface to the concrete and the block was found to be as porous as ever after the surface of the concrete was ground off.

In other words; calcium hydroxide actually assists in the absorption of water and the block becomes waterproof on the surface.

A positive waterproofing as distinguished from that of hydrated lime, which might be called a negative waterproofing, would consist in a surface coat of asphalt or asphaltic material. One interesting thing which was discovered during the course of the experiments was the fact that waterproofing, instead of diminishing the compressive strength of concrete, seemed if anything to increase it, which superficially was a contradiction of the tests carried out by the Bureau of Mines, although further study of those tests showed them to be in conformity with these experimental results. It can therefore perhaps be safely said that waterproofing materials ought to increase the strength of concrete if the concrete is permitted to dry out in contact with air. Some interesting discussion developed more fully the points already brought out in the abstract of this paper and also indicated that similar experiments had been carried out by Bechold on plaster blocks which confirmed Professor White's conclusions with regard to waterproofing materials.

MEMBERS AND GUESTS OF THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS ABOUT TO INSPECT THE VIRGINIA-CAROLINA CHEMICAL CO. WORKS

The Density of Lime as a Function of Burning Conditions

Prof. J. R. Withrow, of Ohio State University, gave a preliminary outline of some experiments which were in process at Ohio State on the burning of lime. It is his purpose to carry out in a miniature limekiln, which has been used in some fuel studies at Ohio State, the effect of time and temperature of burning on the properties of lime and the effect of the variation in the source of material. In carrying out a preliminary set of runs he has had to work out a new method of density determination which has to do with particle density and not bulk density. It is based originally on Washburn's porosity test with some modification thereof. The data obtained are plotted in various ways which it will not be necessary to discuss at the present time, as the data is somewhat inconclusive, but the work promises to develop some very interesting relationships and is being carried on in close co-operation with the extensive research work of the National Lime Association.

A GLIMPSE OF INDUSTRIAL RICHMOND WITH THE MAJESTIC JAMES RIVER IN THE BACKGROUND

Other Technical Papers

In addition to the symposium there were a number of other technical papers of importance. In the issue of Dec. 13 we published the paper by Prof. W. L. Badger, J. C. Wood and E. R. Whittemore on "An Analysis of Stirrer Performance." No discussion of the paper is therefore necessary in this report. In the discussion of the paper Mr. Field read an analysis of the various stirring operations in industry and the various types of stirrers in use.

H. D. Edwards, of the Linde Air Products Co., presented a paper on "The Use of Propane in Refrigeration." An interesting recent development in this field has interest to householders and other users of relatively small refrigeration units. Propane has many advantages. It has no corrosive action on metals and its water solution is harmless. It is stable, can be used in ammonia installations, produces lower temperatures than ammonia and is not dangerous except when it displaces the oxygen necessary for respiration. Considerably more expensive than ammonia, it is not expected to displace it, but will find an extensive use in its own field.

W. B. Pratt, of Boston, read a very interesting paper on "Sulphur Substitution Products of Terpenes." The work was undertaken to throw some light on the vulcanization of rubber, and the simpler substances were studied. How is sulphur combined in such compounds? Probably it is largely molecularly combined in several positions in the molecule. These facts have been established. There is some doubt as to the rest of it, however. The paper aroused some interesting comment.

Prof. J. H. James, of Carnegie Tech., made a further report on his experiments with oxidized oils. A

complete discussion of this paper will be postponed till a later issue. Another report of progress in a special field was made by Prof. Edward Bartow, of Iowa, "The Purification of Sewage by Aëration in the Presence of Activated Sludge." Typical recent installations were described, such as those in Chicago, Milwaukee and Houston, all operating on the diffusion process. The mechanical aëration principle used in England was also described. Various types of aërators and settling tanks received attention, and it was pointed out that practical demonstrations have shown the value of the dried material as fertilizer. Problems in the disposal of packing-house waste were also considered, the sludge rising to the top after treatment with H_2SO_4.

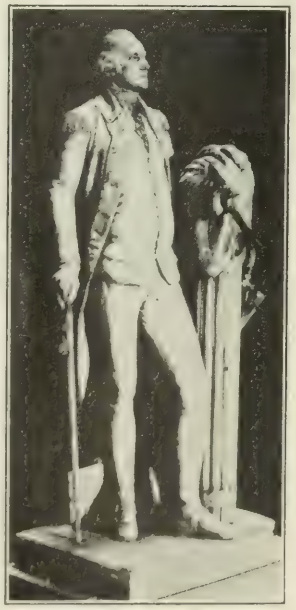
Absorption of Gases in Towers

Three papers on this general subject were presented. All three were definite contributions to the modern conception of chemical engineering as a study of unit processes. It was unfortunate that preprints could not be obtained, for most of the auditors were utterly unable to follow the analysis, which was essentially mathematical.

The paper by F. C. Blake, of the du Pont company, on "The Resistance of Packing to Fluid Flow" derived several relationships, assuming first, a dimensional homogeneity in the packing, and second, where the packing is irregular as in pumice, etc. The relationships plotted were values of $\frac{Pd}{M^2}$ as ordinates and $\frac{M}{\mu}$ as abscissas, where P is the pressure gradient, d the density of the fluid, M the mass velocity and μ the viscosity. Experiments showed that a relationship of this kind does exist.

Data with one fluid can thus be used to estimate the pressure drop with another fluid or at different temperature.

W. B. van Arsdale, of the Brown Company, discussed "The Effect of Rate of Flow on Absorption of Gases," and so did Prof. R. T. Haslam, of Massachusetts Institute of Technology. Mr. van Arsdale is after a fundamental equation (consequently not simple) which will apply to a wide range of tower design and conditions of operation. Previous work with constants based on the assumption of uniform temperature and uniform flow may vary as much as 300 per cent. It is certain that the volume of gas varies; the heat of solution also varies. Solubility does not follow Henry's law and there are undoubtedly cases where slow side reactions affect the results. Performance of towers may be expressed as an absorption coefficient, absorption factor, per cent saturation of liquid, per cent removal of gas or by a so-called solute transfer coefficient.



GEORGE WASHINGTON
Magnificent statue in the state Capitol of Richmond.

The paper is too full of meat to stand a short abstract. It can perhaps best be described as an attempt to determine by mathematical relationships the optimum style and size of the unit packing, the ratio of height to diameter of tower, the ratio of liquid supply and of gas supply per square foot of cross-section and the temperatures of both phases. Each of these factors affects the transfer coefficient.

Professor Haslam's paper reported results obtained on tower efficiency in some experimental work at one of the experimental plants. It must be admitted that M.I.T. never had a reputation for dodging mathematics and therefore if, in figuring tower efficiency, or K_A as they call it, they lump several effects into a general and approximate constant, serious consideration must be given the question before concluding that the analysis is not rigid enough. After all, results within 10 or even 20 per cent are as close as can be expected in designing such equipment. It remains for further data to establish whether a more rigid analysis is necessary. There is no essential disagreement in the two papers.

The final paper was a most entertaining and instructive one by Dr. Jerome Alexander on "The Importance of Impurities." Many examples of the value of minute traces of foreign material were mentioned, extending from the iodine in food, absence of which causes goitre, to such industrial applications as the Welsbach mantle.

Something Better in Enamel Smelters

Principles and Practices of Metallurgical Furnaces Successfully Applied to Terra Cotta Manufacture

AT THE MEETING of the Chicago Section of the American Ceramic Society, Dec. 2, 1922, H. E. Davis, of the Northwestern Terra Cotta Co., outlined the principles of design and construction which have been used in a recently completed enamel smelter. Metallurgical furnace experience has been adapted to the requirements of enamel smelting and it is expected that operating results will prove the advantages of this type.

Desiring something more economical than the method of smelting enamel first in saggers, a careful study of available smelters was made and the conclusion was reached that it would be best to have one designed by engineers familiar with the latest developments in metallurgical furnaces. The Singers-Kennedy Construction Co. was given the problem of designing and building as good an oil-burning furnace as possible for the purpose desired. The furnace as constructed is 12 ft. long, 7 ft. wide and about 6 ft. high.

Burners and Combustion Chambers

Gas oil (34 to 36 Bé.) is delivered to Advance Furnace & Engineering Co. burners at 20 lb. pressure, being heated in a steam box to about 130 deg. F. Air is furnished by a Roots blower at about 15 lb., with no preheating. The atomized oil is further broken up by being sprayed against a quarter sphere of carborundum suspended about 8 in. in front of the burners.

The combustion chamber is 4 ft. wide at the burner end, narrowing to a 2-ft. opening into the smelting chamber. The arch slopes down and the sides slope in, the entire length being about 30 in., which has been found necessary for completely burning oil, and delivering only hot gases to the smelting chamber. Complete combustion is effected largely through radiant heat, thrown back from the side walls of the combustion chamber. The angles of these are so designed as to

throw heat from the hottest portion back at the burner openings. Of the air required, 50 per cent is taken in through the burner ports and 50 per cent may be supplied through two more ports alongside of the burners. These can easily be closed off with a soap brick when desired.

Smelting Chamber

While many enamel furnaces have an arch which slopes down toward the center of the bath, thus forcing the hot gases into close contact with the enamel at high velocity, exactly the opposite principle was used in this smelting chamber. In accordance with metallurgical experience, the arch is built like a turtle back, arched both lengthwise and crosswise. The hot gases thus slow down to a rather lazy passage over the center of the bath, permitting a maximum amount of heat to be given up. In addition to this, the shape of the arch concentrates the radiant heat at the thickest part of the bath where it will do the most good.

Drying Table

At the end of the kiln the waste gases are drawn through a flue which is covered with a 3x6-ft. drying table to dry the quenched frit before grinding. It is estimated that the gases will reach the drying table at approximately 1,400 deg. F. and the stack at about 1,000 deg. F.

Insulation

Loss of heat through the furnace walls is reduced to a minimum by efficient insulation.

The bottom of the kiln is 11 in. of Sil-O-Cel brick underneath three courses of firebrick and a 6-in. hearth-tile. The walls are 9 in. of Sil-O-Cel brick, outside of 9 in. first quality firebrick and 6 in. hearth-tile down at the bath level.

The crowns are all 9 in., with Sil-O-Cel C-3 grouted over, thinly of course, at the center to prevent holding too much heat at this point. All arches and inner walls are made with "buttered joints" of high-grade fireclay and pointed up with high-temperature cement. As the insulating brick form the outer walls and are very soft, the entire furnace was incased in an armor of $\frac{3}{16}$-in. steel plate. This is a great protection to the insulation from knocking against it, and also prevents heat losses through cracks which might develop. The drying table and the flues leading in to it are all well insulated. The charging door is made of C-3 Sil-O-Cel, 9 in. thick.

Some interesting data on the value of insulation were found by actual tests. A 13-in. non-insulated firebrick wall has a loss of 1,450 B.t.u. per square foot per hour opposite the hottest point; $4\frac{1}{2}$ in. insulation reduces this to 350 B.t.u. per square foot per hour. An 18-in. firebrick wall non-insulated loses 1,100 B.t.u. per square foot per hour. The same thickness of wall built of 9-in. firebrick and 9-in. insulation, as in this furnace, loses 225 B.t.u. per square foot per hour.

Hearth Lining

Although the ideal hearth lining would be one tight enough to prevent absorption of the molten frit and yet open enough to resist sudden temperature changes without spalling, such an ideal is difficult to find in practice. In this furnace an experiment is being made with large blocks of Indiana clay burned almost to vitrification. The body used for this is the same as that to which the enamels are fitted in the ware, so that there will be little danger of attack by the molten frit. It is hoped that spalling will also be reduced. The interior of the hearth is 3x6 ft., made up of blocks 6x12x18 in.

Data on Theoretical Fuel Consumption

Although no tests have been made, the efficiency may be taken conservatively as 30 per cent, since the furnace is patterned very closely after a heat-treating furnace which had an efficiency of over 40 per cent on actual test. The maximum batch will be 400 lb. to be melted at 2,500 deg. F., specific heat about 0.3. There will thus be required $400 \times 2{,}500 \times 0.3$, or 300,000 B.t.u., but as the efficiency is 30 per cent, 1,000,000 B.t.u. will have to be supplied. With oil at 140,000 B.t.u. per gallon, this would mean about 7.2 gal. of oil per heat.

No enamel has been melted as yet, but preliminary trials to test out the burners and to dry out the structure seem to indicate that the furnace heats up very rapidly and that the combustion chamber does all that is expected of it.

A New Artificial Zeolite

Recently the British firm of Crosfields, manufacturer of soda and sodium silicate, has succeeded in making a satisfactory artificial zeolite. This material, which is being marketed under the trade name Doucil, is competitive with the semi-natural Permutit, Refinite and Borromite products. According to the British patent specifications Nos. 142,974 and 177,746, there are two different types of product, the former being more suitable for drying air and recovering solvent vapors on lines similar to those adopted in America by the Silica Gel Corporation, while the latter is more suitable for water softening and purification. The former product is obtained by neutralizing by means of hydrochloric acid about 50 per cent of the soda in a dilute solution of silicate of soda, the final product containing on the dry basis about $12\frac{1}{2}$ per cent Na_2O and 87 per cent of SiO_2. Doucil, on the other hand, is prepared by intimately mixing at temperatures below 20 deg. C. dilute solutions of sodium aluminate and "neutral" sodium silicate in order to obtain a product containing between 6 per cent and 16 per cent of alumina based upon the total solids originally present in the mixture. In both cases a stiff gelatinous mass is obtained after it has stood for a few minutes and by carefully drying at a gentle heat down to about 60 per cent moisture content it is possible to lixiviate the mass, remove the soluble constituents and leave the granular, semi-transparent and insoluble artificial zeolites ready for use. By varying the strength of the solution and also the final moisture content, it is possible to obtain gels containing various percentages of alumina between the limits given above.

The product is being sold at 11 cents a pound and it is stated that 1 cu.ft. will soften 1,000 gal. of water containing ten parts of calcium oxide per 100,000 or the equivalent of calcium and magnesium oxides. For regeneration 4 lb. of common salt is required per cubic foot of the material, and this is believed to be considerably less than the amount required by other zeolite materials. A guarantee is given that 5 per cent of the dry weight of the material is capable of being exchanged for calcium compounds and in experimental work 7 to 8 per cent has been obtained. Experiments are also in progress in regard to solvent recovery and air drying, but the makers' intention is to sell the material and not to manufacture actual plants.

Fundamental Properties Of Commercial Limes

II—The Settling of Milk of Lime Suspensions

By M. E. Holmes*, G. J. Fink† and F. C. Mathers‡

This Article Deals With the Factors Affecting the Settling Characteristics of Lime Suspensions and Presents Comparative Data on a Large Number of Commercial Quicklimes and Hydrated Limes

THE characteristics of a milk of lime suspension are of considerable importance in connection with the use of lime in many chemical and industrial processes. The rate of settling or permanency of such a suspension is of particular and direct importance in such processes as the unhairing and plumping of hides, the preparation of glue and gelatin, the defecation of sugar juices, preparation of whitewashes and lime paints, the preparation and use of sprays and insecticides, the treatment of water supplies, sewage disposal, treatment of textiles, and saponification and clarification of fats. In other processes involving the use of lime, such as causticizing, preparation of bleach and bleaching solutions and a number of processes in other industries, this property is of indirect importance in influencing the rate of reaction, rate of settling of sludges, etc. The particle size and nature of the ultimate product in the case of certain chemicals may in fact be more or less affected by differences in settling rates of the lines used.

Kohlschutter and Walther[1] have investigated the settling rates of suspensions obtained by slaking calcium oxide prepared from various sources and slaked with solutions of substances such as calcium chloride, oxalic acid or sodium carbonate. Determinations were made on products obtained by use of sufficient solution to yield a wet hydrate and no data were obtained relative to dry hydrates. They found that the rate of settling was greatly influenced by the kind and concentration of the solutions used in slaking the quicklimes. Their results are of theoretical interest only because c.p. oxides were used and concentrations of the slaking solutions which were employed were far greater than would be considered practical in industrial operations.

It is the purpose of the present article to present the results of a comparison of settling rates of a large number of representative commercial quicklimes and hydrates and the results of a study of the conditions affecting the rate of settling. Part of this work was done in the laboratory of the National Lime Association and part under a fellowship agreement with Indiana University.

The determinations of rates of settling reported here were made on portions of the same stock samples of quicklimes and hydrates whose available lime content were reported in the first paper of this series.[2] These limes represent all types of lime, varying widely in physical properties and ranging in chemical composition from the high-calcium to the high-magnesium type, and are of the average quality furnished continuously to the trade by companies located in all sections of the country.

The rate of settling was determined as follows:

(1) *Quicklimes.* Seven and one-half grams of the quicklime was carefully slaked to produce a putty of approximately normal consistency and permitted to stand for 24 hours. After this period of curing the putty was transferred to a 100-c.c. graduated cylinder having an internal diameter of 23 mm. and water added to bring the total volume to 75 c.c. The cylinder was then shaken to disintegrate and disperse the lime, after which the volume was made up to 100 c.c. and the cylinder again shaken for 30 seconds to insure uniform mixing. It was then permitted to stand without disturbance and the top of the lime suspension as it settled out was read at intervals of 5 minutes. The final volume (after 24 hours) was recorded in each case.

(2) *Hydrated Limes.* Ten grams of hydrated lime, equivalent approximately to 7½ grams of high-calcium quicklime, was mixed thoroughly with sufficient water to produce a putty of normal consistency and the paste permitted to stand for 24 hours to insure wetting of all the particles. This was transferred to a graduated cylinder and the settling rate determined as for quicklimes.

As indicated below, the concentration of the milk of lime suspension affects the rate of subsidence and the nature of the settling phenomenon. Consequently it was necessary in these tests to select such a concentration that the suspended material would settle *en masse* in order to get anything like an accurate comparison of the various limes. It was found that concentrations below 10 grams of hydrate or 7½ grams of quicklime per 100 c.c. would not give a definite line of demarkation in many instances. These quantities were therefore chosen as satisfactory. With most limes the supernatant liquid became quite clear after the first few minutes. In those instances where a slight milkiness persisted the quantity of material remaining in suspension represented only a very small fraction of the total solids present and would be insignificant in most processes involving such suspensions.

The data on settling of suspensions of freshly slaked quicklimes are tabulated in Table I and of suspensions of hydrated limes in Table II. Records were obtained at intervals of 5 minutes, but only a portion of the data is recorded here. In Tables III, IV, V and VI the limes are classified as to available lime content.

Curves obtained by plotting the volume of sediment against time for typical quicklimes and hydrates are shown in Figs. 1 and 2.

The data obtained in the study of the conditions affecting the rate of settling are given in Tables VII, VIII, IX and X.

Discussion

It will be seen that the curves showing the settling rates of typical hydrates and quicklimes are made up of two portions. The portion representing the earlier stages of the process more truly represents settling rate. As the settling continues the concentration of particles in the lower part of the settling tube is slowly increased and this zone of thickening, gradually merging with the zone of free settling, results in a slowing up of the rate of subsidence. Any further subsidence of the solids then really represents a dewatering effect. Although this last effect is characteristic of each particular lime, the real differences in settling characteristics are indicated by the upper portions of the curves. For that reason we have tabulated in the data the time required to settle to a volume of 50 c.c. For most purposes this value serves to differentiate and characterize the different limes.

The lower portion of the curve representing thickening or dewatering is interesting in connection with certain uses of lime, and data on the water-holding capacity of the different limes which will be published later will undoubtedly bring to light certain interesting differences. Some of these limes settle quickly to a thick dense mass, while others form a loose, free-moving mass with a very high water content. These differences are due chiefly to differences in the physical characteristics of the flocs and their interholding capacity.

It is apparent from the data in the tables and the curves that, in general, suspensions of freshly slaked limes settle much more slowly and vary much more widely in their rate of settling than suspensions of commercially hydrated limes. Various factors are effective in producing these differences and numerous theories have been proposed to explain them.

Factors Affecting Rate of Settling of Suspensions in General

A number of factors have been recognized as affecting the rate of settling of the particles which make up a suspension.

(1) *Density of the Material.* The specific gravities of the calcium hydrated limes examined vary from 2.170 to 2.558, with an average value of 2.281, and of the magnesium hydrates from 2.237 to 2.586, with an average of 2.433. The latter as a class settle faster, but within each class the settling rates are not in the same order as the specific gravities and there is no discernable correlation between the two properties. The effect of other factors governing settling evidently outweigh the effect of gravity in the particular cases.

(2) *Size of Particles.* In general fine particles will settle less rapidly than coarse particles of the same

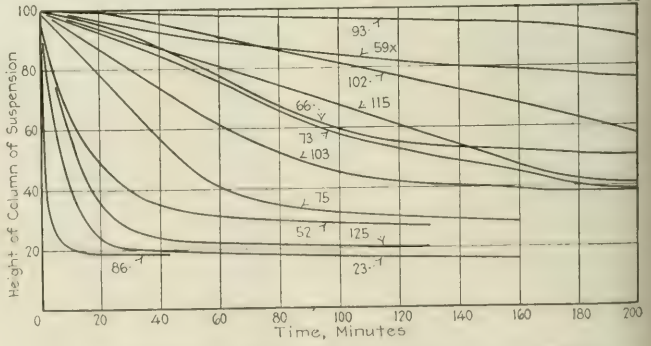

FIG. 2—RATES OF SETTLING OF TYPICAL FRESHLY SLAKED LIMES

absolute density. In practice, and this is particularly true of limes, the particles of a given material are rarely of uniform size and the nature of settling phenomena is more strictly a function of the relative proportions of particles of different sizes than of either the mean size or the true density of the material. It is conceivable that two samples might appear to settle at the same rate as judged by the subsidence of the column of suspended matter, yet the percentages of material remaining in suspension in the two at any given time might be considerably different as a result of the different rates of settling of the different sized particles, the determining factor in the rate of settling according to this standard being therefore the rate of settling of the finest particles. The finer these become the less is the effect of gravity and the nearer the approach to the colloidal state and the better the conditions for a permanent suspension.[3]

It is probable that in the case of most hydrated limes the colloidal state is not reached by a very appreciable proportion of the mass. There are very probably larger proportions of the more finely divided material and perhaps more colloidal matter in the suspensions of freshly slaked lime. Although no determinations have yet been made of the relative proportions of particles smaller than 250 mesh in these limes, it is probable that such differences may largely account for the variations in rates of settling. In the case of the hydrated limes there is no apparent correlation between the settling rate and the percentage of material passing the 250 mesh. The factors involved in the slaking of limes which would tend to affect particle size are discussed below.

(3) *Concentration.* The effect of concentration in the settling of suspensions is evidenced by the fact that in the case of very dilute suspensions containing some rather finely divided material there is no definite line of demarkation between the dispersed material and the dispersing liquid, whereas, if the concentration of the solids is increased, a concentration will be reached at which a line of demarkation will be shown. In the case of the dilute suspension a certain separation or classification of particles takes place and there is a free movement of individual particles, the coarsest settling first and the finest remaining in suspension. In the other case, however, there is no independent movement of individual particles, the coarser particles being retarded by the finer material which they carry down. As stated above, such concentrations were used in these tests that in most instances a definite line of demarkation was obtained.

(4) *Charge on the Particles.* In suspensions where a portion of the material approaches the colloidal state the effect of the charge on the particles is to be considered, the stability of such suspensions being determined by the conditions governing or affecting the nature and intensity of the charge. No specific data on this point in relation to limes are yet available, but the general effect of the addition to limes of various substances including salts is indicated below.

(5) *Aggregation or Flocculation.* The conditions governing the tendency of the individual particles of a dispersed material to form aggregates must necessarily influence the rate of settling of that material. These conditions as applied to limes will be considered in some detail.

[3]Deane, "Settling Problems," *Trans.*, Am. Elec. Soc., vol. 37, p. 71 (1920). An excellent discussion of the factors governing settling. See also "Third Crop Pest and Horticultural Report," Oregon Agr. Col. Exp. Sta., Jan. 10, 1921, and *J. Ind. Eng. Chem.*, vol. 14, p. 314 (1922).

Effect of Conditions of Slaking

In the production of hydrated limes and in the preparation of suspensions of freshly slaked quicklime there are a number of conditions imposed which may determine to a marked extent the above-mentioned factors and hence affect the settling rates of the products. Among the most important of these may be mentioned:

(1) *Amount of Water Used in Slaking.* Presumably the difference between the settling rates of hydrated limes and freshly slaked limes can be largely accounted for by the different conditions in hydrating, the most important of which is the relative quantities of water used. Commercial hydrated limes are usually made under conditions which produce a dry material without excess of water, while the milk of lime obtained from the quicklime under consideration was always obtained with excess of water to produce a wet product. The specific effect of these different conditions is quite strikingly illustrated by the data obtained by slaking the same limes in one case to a dry hydrate and in the other to a wet hydrate. These data are given in Table VII.

Whether these differences are due alone to differences in size of particles or the formation of aggregates, which may be a manifestation of polymorphism, or to the production of actually different chemical individuals such as differently hydrated molecules is uncertain. There are evidences of aggregation of particles in case of the commercial hydrates[4] and also certain indications of the existence of crystalline hydrates[5] and hydrated calcium hydroxide.[6] The variations in quantities of water affect not only the temperature of reaction but also the rate of reaction, both of which may affect the physical and chemical properties of the product.

(2) *Temperature of Slaking* and (3) *Temperature to Which Hydrate Is Heated After Slaking.* Both of these conditions are different in the production of lime suspensions in practice, and their exact effect is not clearly defined in the data comparing all limes, but it is specifically indicated in Table VIII. In experiment No. 1, the suspension was prepared by dropping a sample of N.L.A. quicklime, which had been heated to redness, into 50 c.c. of boiling water. No. 2 was prepared by using the cold lime and cold water. In experiment No. 3 another portion of the red hot lime was dropped into 50 c.c. of ice and water.

It is evident that the lower the temperature of slaking the slower the hydrate settles. Additional data in this connection will be published later.

The temperature to which the hydrate is heated after slaking is different under the conditions obtaining in the processes of wet slaking and dry slaking. The different commercial hydrates are very probably produced under considerably different conditions as regards the temperature to which the already hydrated particles are heated, although no definite data are available on this point. Unpublished data do indicate that

Abs.*, vol. 10, p. 1456 (1916).

hydrates prepared in the laboratory and heated to temperatures above 100 deg. but below 450 deg. settle faster than those not so heated. It is quite possible that in the commercial hydrator temperatures may rise locally to a sufficient degree to form an "oxyhydrate" which may show a tendency to crystallize and increase the rate of settling.[1]

(4) *Use of Chemicals in Slaking.* Data recorded in Table IV show the effect of slaking the lime in sugar and calcium chloride solution.

It is apparent that the rate of settling is accelerated by the presence of calcium chloride in the slaking water used in producing the hydrate and retarded by the presence of sugar. The effect of adding sugar or salt after the suspension is made is of relatively little importance.

(5) *Time of Soaking of Hydrate.* As evidence of the possible presence of aggregates in commercial hydrates as the result of which their settling rates would be greater than those of the freshly made wet hydrate it has been shown that the length of time which a hydrate is soaked in water changes its rate of settling to a noticeable extent. The rate of settling immediately after mixing is more rapid than the rate after standing in contact with the water for some time. Data upon which this conclusion is based are given in Table X.

Conclusions

The data given in Tables III to VI indicate that suspensions of magnesium limes as a class settle much more rapidly than do suspensions of calcium limes. This may probably be explained by the fact that in calcining a magnesium lime the temperature required to decompose the calcium carbonate is very much above that required for the magnesium carbonate. The resulting magnesia is therefore superheated and is not so thoroughly dispersed in the slaking of the lime. The suspensions of the material would consequently be expected in general to contain a large proportion of coarse material and to settle more freely than that obtained from the high-calcium lime, which may be quite thoroughly disintegrated and dispersed.

From a consideration of the data in these tables it can also be said that those limes, both calcium and magnesium, which as a class have a high available lime content, settle slowest. It would naturally be expected that the higher this value the greater the number of patricles of the quicklime to undergo reaction during hydration. This would result in a breaking down of aggregates and a more thorough dispersion of the suspended particles in the milk of lime.

There are some notable exceptions to this conclusion. Lime No. 87, for example, with an available lime content of 94 per cent, settles out immediately. It is apparent, therefore, that in some cases factors other than those considered are of much importance.

A third generalization can be made—viz., that among the calcium limes the freshly slaked materials settle more slowly than the suspensions made from the mechanically hydrated limes. As pointed out above, the conditions obtaining in the mechanical hydration are such as to favor higher temperatures, which would tend to induce certain chemical reactions resulting perhaps in the formation of small quantities of an "oxyhydrate" which is described by Emley[2] as "a hard, gritty, yellowish material which shows a tendency to crystallize." The aging of the incompletely dried hydrate might eliminate this condition to some extent, but on the other hand it may induce aggregation or crystallization of the amorphous hydrate, resulting in slightly coarser and less easily dispersed particles. The sum total of this effect would vary with the various lines depending upon the other properties of the lime.

It will also be noted that the differences between the settling rates of hydrates are much less than the differences between the rates of settling of the freshly slaked material. Slaking with excess of water brings out the individual characteristics of the limes in this respect, while mechanical hydration tends to smooth out or reduce these differences. Extreme conditions in rate of settling are therefore best obtainable with quicklime. On the other hand, the use of hydrated limes will result in greater uniformity. There are a few exceptions to the conclusion that hydrated limes settle more rapidly than freshly slaked limes. No. 86 is an example. This discrepancy can be explained in this case by the fact that it contains a considerable amount of silica which is removed in the mechanical process of hydration, thereby eliminating a considerable amount of rapid settling material.

The differences between the slaked magnesium limes and the corresponding hydrates are much less than in the case of the calcium limes. The conditions obtaining in the mechanical hydration and storage, as compared with the slaking process, are probably more favorable for hydration of magnesia, thereby minimizing the difference in the degree of dispersion and settling rate of the magnesium limes.

There are indications that the lower the temperature of slaking the slower the hydrate settles. After-heating, if not excessive, tends to increase the rate of settling.

The effect of chemicals in the slaking solution is very marked. Certain chemicals, such as sugar, reduce the rate of settling and others, such as $CaCl_2$, increase the rate of settling.

The effect of increased time of soaking of the mechanically hydrated material is to decrease the rate of settling.

A survey of the data as a whole shows that it is possible to obtain a high-grade lime of almost any desired settling characteristics and that the settling characteristics of any given lime can be materially altered by suitable treatment.

Use of Gunite in Preserving Mine Timbers

A most important question, on which adequate data are not available, is the effect of gunite in retarding the decay of timbers to which the gunite is applied, states the Bureau of Mines in Serial 2397, just issued. It is obvious that such information can be obtained only by observation of gunited timber in comparison with exposed timbers under similar conditions over a period of years. Experiments at the United Comstock, North Star and Empire mines and at the University of California are being watched carefully by the Bureau of Mines, and the final results will be published. From what has been learned of the density and non-porosity of gunite and its resistance to the absorption of water, it seems reasonable to believe, if sound timbers free from decay are carefully and completely covered with gunite, that the gunite coating will protect the timber against the attack of fungus and insects, and thus retard decay.

Polishing Aluminum and Its Alloys for Metallographic Study

By E. H. Dix, Jr.
Chief, Metals Branch, Engineering Division, Air Service

A METALLOGRAPHIC STUDY of aluminum and its alloys presents difficulties which are unique to this class of material. Aluminum itself is very soft and contains, even in its purest commercial form, constituents relatively much harder formed with other elements such as iron, silicon and copper. This combination of very soft matrix which is easily scratched, and hard particles which are easily blurred over, presents an exceedingly difficult polishing task. In addition the alloys are very difficult to etch, for in any given alloy there are usually three or more constituents to be identified. With our present methods of etching it is possible to bring out the grain boundaries and perhaps identify one of the constituents present, but the etching generally obscures the remainder of the structure.

Recently it has been found possible to obtain a polished surface practically free from scratches and in which the hard constituents stand out in slight relief and in varying colors so that with few exceptions they can be identified without etching. The following is a brief description of the methods employed for this purpose in the metallurgical laboratory of the Engineering Division of the U. S. Army Air Service, McCook Field.

The first operations in the preparation of a specimen differ little from those used for other materials. Sawing should be performed with care so that the depth of metal disturbed is not so great but that it is entirely removed by grinding. Grinding is preferably done on two wheels, a coarse one to remove all of the material disturbed by sawing and a finer one to furnish a plane surface relatively smooth for subsequent operations. The specimen should be held against the coarse wheel so that the cutting is in a direction at right angles to the striations from the sawing. It is well to do more than just take out these grooves, because there is always a flow of metal underneath the saw tooth. Cutting on the fine wheel is again at right angles to the striations left by the coarse wheel, and this process of crossing the direction of cutting is followed in the subsequent polishing on papers; it is an old story to metallographers.

FIG. 1—DARK SILICON AND HALF-TONE $FeAl_3$ IN ALUMINUM INGOT. UNETCHED. × 1,000

Polishing on papers is best accomplished by hand, using a smooth swinging motion from the elbow with a stroke of 4 or 5 in. The pressure should be even, but not so light that the cutting is too slow; as the finer papers are reached the pressure should become lighter and lighter, because the heavier pressures at this stage make deep scratches which take longer to remove on the next paper. Care should be taken that the specimen is not rocked, causing it to be high in the center and low on the edges, because on the next paper it will be necessary to take down this high center before the scratches on the edge are reached.

Immediately after the grinding operation the paper may be any fine grade emery paper or grade No. 2 of the "Hubert Papers." (These are specially prepared

for metallographic purposes, and a similar line known as "Manning Papers" can also be obtained.) Then in succession should be used Nos. 1, 0, 00 and 000. Cover the 00 and 000 papers with paraffine to prevent loose emery particles from becoming imbedded in the soft aluminum. This may best be accomplished by dissolving the paraffine in kerosene and painting the liquid over the paper. By the use of paraffine, the specimen should remain bright and clean all through the operations, and after polishing on the 000 paper should have fine striations all in one direction and no traces of any scratches from the previous operations.

The specimen should then be washed free from all particles of emery and grease. Small pores, so common in the cast alloys, should be carefully cleaned; otherwise, particles of emery are likely to remain, only to come out later on the polishing cloth and form deep scratches.

Wet polishing with some fine abrasive, such as Norton 65 F alundum, is the next operation. This is accomplished on a horizontal disk about 8 in. in diameter rotating at from 500 to 600 r.p.m., and covered with soft broadcloth having plenty of nap. (The "Kitten Ear" variety or imported "Priestly Cloth" has been found to be very satisfactory.) The abrasive is put in a flask filled with water and shaken up. The pad is thoroughly wetted and supplied with abrasive from the flask held in the left hand, the direction of rotation being counter-clockwise, while the specimen is held in the right hand so that the motion of the wheel is at right angles to the striations left from the 000 paper. It is moved radially back and forth from within 1 in. of the center to within about 1 in. of the outside, care being taken not to turn the specimen on the pad. This prevents a particle of abrasive from cutting a groove in the specimen, as it would be likely to do if it were held in one place. The specimen is lifted from the pad and turned through 180 deg. four or five times during this operation in order to prevent a surface flow of metal in one direction. During this time the coarser particles of 65 F have settled to the bottom of the flask, and if it is not shaken the abrasive in suspension becomes finer and finer, so that by the time all of the scratches due to the fine paper have been removed the heavier scratches caused by the 65 F have also been reduced by the finer particles of the abrasive. Examination under the microscope at this time should reveal the structure of the alloy somewhat obscured by very fine scratches all in one direction.

These are removed on a second pad of the same kind of cloth moistened with distilled water. On this is sprinkled magnesia powder (sold as "Heavy Magnesia Powder") which is thoroughly worked into the cloth by the hand and any coarse particles removed. The specimen is then held lightly on the pad, crossing the scratches from the previous operation. Move it in the same manner as when using the 65 F, except that the stroke is shorter and nearer the center of the pad. If the pad becomes too dry before all of the previous scratches are removed, the wheel is stopped, moistened, and more magnesia worked in. This is repeated until all of the scratches from the 65 F are removed. In this operation it is important to lift the specimen from the wheel frequently and rotate it through 180 deg.; otherwise a surface flow of the metal is sure to result.

The pad is now washed practically clean of the magnesia by adding more water and working out the powder with the hand. The specimen is then held near the center of the wheel, and is slowly rotated in a plentiful supply of water. The object of this operation is to remove the scratches left by the magnesia, but it must be performed with the greatest care. The pressure and length of time required depend on the nature of the specimen, and can be learned only after considerable experience. If this operation is properly performed, the specimen takes on a high polish and is practically free from scratches. It is quite possible that the specimen may become tarnished before the scratches are removed. The tarnish first appears around the hard constituents, particularly between the fine particles in eutectic areas. It may usually be removed by moistening the pad, dusting on a light supply of magnesia, and holding the specimen very lightly on the pad with a small radial movement back and forth, care being taken not to turn it. This operation leaves very fine striations all in one direction, but gives a clear structure. Specimens very prone to tarnish may be left in this condition; however, these striations can usually be removed by cleaning the pad as before and rotating the specimen with a change in pressure.

Alloys containing a considerable amount of very hard constituent, for instance $CuAl_2$, should be given a reasonably heavy pressure, but for the purer aluminums the pressure should be very light. Often, repeated

trials are necessary before a satisfactory polish is obtained. Polishing too long causes the hard particles to stand out in undesirable relief, giving black outlines and making focusing difficult. It is often necessary to go back to the 000 paper to correct this trouble. Too heavy pressure or too dry a pad when using magnesia causes the specimen to show milky streaks. These may be removed by polishing with a light supply of magnesia at right angles to the streaks until they disappear.

Magnesia as a polishing powder for aluminum was first mentioned by Hanson and Archbutt[1] in 1919 and is largely responsible for the success with which the polishing is now being accomplished. The powder feels coarse, but is so soft that it cuts without making deep scratches. It is desirable to use freshly distilled water with the magnesia; otherwise hard particles of carbonate form which scratch the specimen. The moisture of the air will do the same thing if the magnesia is not carefully washed from the pad after using. Soaking the pad in dilute HCl removes all traces of these hard particles. It is a good plan to soak the pad frequently in the dilute acid over night and then carefully wash out the acid before using in the morning.

When the specimen has been properly prepared, the structure as seen under the microscope is very striking, especially for magnifications of 500 or 1,000 diameters. The constituents are revealed in characteristic colors and often form geometric figures. Silicon is perhaps the easiest to recognize, appearing a dark slate with purple tinge and photographing black, as shown in Fig. 1, of high-silicon ingot (Cu 0.32, Si 0.99, Fe 0.51, Mn 0.0, Al 98.18) remelted and cast in standard tensile test-bar. The $FeAl_3$ needles are lighter than the silicon and have a lavender tinge. They appear in half-tone in the same figure. In addition to the needles there is a constituent, probably a compound of iron and silicon, that forms skeletons, often resembling "Chinese script," as in Fig. 2, of No. 1 ingot (Cu 0.11, Si 0.31, Fe 0.58, Al 99.0). It also seems to occur in globs and sometimes in stringers (see Fig. 3, of a crankcase alloy high in iron—Cu 6.70, Si 0.57, Fe 1.35). This constituent is the same color as the $FeAl_3$ needles and is probably the constituent indicated by the thermal curves of Merica[2] and the Eleventh Alloys Research Report.[3] It is thought to be a compound containing both iron and silicon. With the present state of our knowledge it is not possible to distinguish between these constituents by etching.

The compound $CuAl_2$ is harder than the other constituents and usually polishes in relief very quickly. It is nearly white with a slightly pink or orange tinge and appears very bright when thrown slightly out of focus. A network structure is formed in alloys containing over 4 or 5 per cent copper, as in Fig. 4, of a crankcase of No. 12 alloy (Cu 8.06, Si 0.78, Fe 0.74). High magnification (Fig. 5) shows $CuAl_2$, $FeAl_3$ needles and fine black particles of silicon.

Mg_2Si has an iridescent blue color and is readily recognized. Large crystals of this compound are shown in Fig. 6, of an alloy made with the proper percentages of Mg and Si to form the compound Mg_2Si (Si 20, Mg 35, Al 45). The same constituent is also closely associated with $CuAl_2$ in Fig. 7. The latter is of a sand-cast and heat-treated alloy, Cu 3.13, Fe 1.40, Si 0.20 and Mg 0.84. A figure pattern of $CuAl_2$ and aluminum contains fine black particles thought to be Mg_2Si, apparently forming a tenary eutectic. Most of the crystals shown in Fig. 6 had an iridescent appearance after the first polish, but on repolishing the true color was found to be a bluish gray. The iridescent appearance of the small particles in which Mg_2Si is usually found in the commercial alloys is thought to be due to a sort of tarnish which is difficult to prevent.

The compound $MnAl_3$ appears nearly the same color as the "X constituent" and often takes a similar form, and it is therefore very difficult to distinguish between them. When found in the same field, however, the $MnAl_3$ is seen to be more of a dove gray, lacking the lavender tinge of the "X constituent." The $MnAl_3$ is also apparently softer than the "X constituent" and in consequence has a dull flat appearance and does not appear bright at the edges when thrown out of focus. Since the "X constituent" does give a bright outline, this serves as a convenient way of distinguishing between them.

It is necessary to caution against hastily identifying

the various constituents by means of the description given above, because due to differences in the polish some very misleading effects may be obtained. In case of doubt it is advisable to repolish, carefully examining the specimen after different stages. This is a particularly valuable precaution just before rotating the specimen on the pad in the final operation, using only water, because it is this last operation that sometimes alters the appearance of the structure. Also, different equipment with other sources of illumination and lens systems will undoubtedly alter the appearance of the different constituents.

This description of the color of the constituents is based on their appearance, using a tungsten arc with a Wratten No. 78 filter. This combination gives a light closely approximating daylight. For photographic work the Wratten E orange filter has been found to give the best contrast.

A set of comparison standards of definite compositions will be found a great aid for the identification of unknown constituents. These samples may be preserved by a coat of cedar oil such as is commonly used for oil objectives. This prevents tarnish and may be quickly removed by alcohol, although if the oil is put on thin and permitted to dry thoroughly, it is not necessary to remove it from the specimen.

In conclusion I desire to acknowledge the very skillful assistance of Clifford McMahon in polishing the specimens, and of J. H. Hester for developing and printing the plates.

Doubling Height of Smelter Stack Causes Fume Damage

The United States Circuit Court of Appeals affirms a judgment for Peter Henke in his action brought against the St. Louis Smelting & Refining Co. for damages to his orchard from fumes of defendant's smelting plant. 277 Federal, 666.

In 1904 defendant constructed a large smelting plant in Madison County, Illinois, near the city of St. Louis, Mo., for the refining of lead and other minerals. Plaintiff owned 30 acres of orchard in the vicinity of the plant, which he claims was permanently injured, caused by poisonous emanations from the plant settling upon his land. He asked for $50,000 damages, and the jury awarded him $4,000.

On the appeal the court says that in the action for damages from the smelter fumes, evidence of the crop produced and the sale thereof is admissible, not as showing the market value of the land itself, but as proving its adaptability to special purpose, in corroboration or support of evidence of market value.

Change in Stack Construction

In the smelter plant as originally constructed and as conducted down to 1915, the gases passed through a long tunnel, or "trail," and through a series of bays for arresting the solid matter, and thence into the air through a chimney 200 ft. high. For the 10 years preceding 1915 no injury accrued to the orchard by the poisonous emanations from the plant, which was about a mile away. But in 1915 such damage did accrue and the court said it may reasonably be concluded that it was through some condition in the plant which did not exist before 1915. It appears that in 1915 the "trail" was out of order, and was being repaired and replaced, and a new chimney 400 ft. high was erected. Plaintiff contended that with the plant in the condition it was prior to 1915, such gases as reached the orchard were not sufficiently charged with sulphur dioxide to injure the orchard, but that in 1915 the intervening and first occurring condition of the "trail" caused so much more of the poisonous substance to be discharged from the chimney that much more of it reached the orchard and did the damage, and that thereafter, through the doubling of the height of the chimney far more of the gases were carried over the orchard, and that a far greater quantity of the sulphur dioxide was thereafter precipitated upon the orchard than had ever been or would have been in the use of the old chimney under normal circumstances. Defendant contended that the height of the new chimney greatly diffused the poison so that in any event, by the time it fell upon the orchard, if any did so fall, it was practically innocuous. From the evidence on these facts the jury found for the plaintiff.

Schooner Sailed With Reasonable Dispatch and Freight on Caustic Soda Must Be Paid

In the cases of the Aegean Trading Co. and others against Seventy-five Drums of Caustic Soda, etc., in the United States Circuit Court of Appeals, 279 Federal Reporter, 109, a decree for Alex R. Mehaffy as master of the schooner A. J. West on his cross action is affirmed.

It was claimed that the trading company, being informed by one Barr, who solicited freight for the vessel, that she had already sailed, took up the bills of lading and paid the freight, but on learning that she had not sailed, stopped payment of the check.

Sailing Delayed by Strikes

It appears that the vessel had a hard time in obtaining her contracts for cargo, then about the time the check was given she suffered from strikes among dockmasters, delaying her departure. Under all the circumstances the court found that the vessel proceeded on her voyage within a reasonable time and that the freight was earned in transporting the caustic soda to Greece. The soda was on board the vessel in January, 1919; libel in Admiralty was filed March 15, 1919, but under an arrangement made in court the vessel was permitted to sail and did sail on March 22, 1919, and in due course delivered the soda to a port in Greece, its destination.

The vessel was about 60 days on the voyage, and consequently the schooner was less desirable as a carrier of merchandise than similar vessels. Also testimony showed that it would have taken her 2 or 3 weeks to load if all her cargo had been loaded at once. The fact that other steamers had been able to obtain cargo and proceed on voyage to Greece, during the period that the A. J. West was loading, did not show that an auxiliary schooner could do the same thing, considering all the circumstances, says the court. In the face of a harbor strike and only after considerable effort and the payment of an exorbitant price for towage was the vessel able to get away. This was held to be reasonable dispatch and the trading company should not have stopped payment on its check.

The Gasification of Ohio Coals—II

Results of a Preliminary Survey Indicate That These Coals Compare Favorably With Standard Gas Coals as Far as Yield of Gas and Byproducts Is Concerned—Discussion of Experimental Results and Comparative Data*

By D. J. Demorest
Professor of Metallurgy, Ohio State University

In THE preceding article it was pointed out, incidentally, that every coal has properties that differ from those of other coals and that to get best results from a particular coal it should be retorted at its characteristic temperature. It would have required, however, many thousands of dollars more than were available for this investigation if each coal had been investigated to discover its optimum operating temperature. Hence, 1,000 deg. C. was selected as being a satisfactory average temperature, the temperature being taken at a point about halfway between the bottom and top of the combustion chamber outside the retort. It would probably have been better if 1,100 deg. C. had been taken as the standard temperature. When this temperature (1,100 deg. C.) is maintained at the point halfway up the retort, the temperature at the bottom (in the combustion chamber) is 1,325 deg. C. (2,417 deg. F.) At times the gas supply was inadequate and the retort temperature fell so low that the retorting results were quite unsatisfactory. For this reason the results on samples 7, 7W, 8W, 10, 10W, which are shown in the accompanying tables, are not fair to the coals they represent, as far as the gas yields are concerned. The coke results are probably not seriously affected, since the coal was kept in the retort until the carbonization was complete, although the quality of the coke may have been seriously affected by carbonizing at the wrong temperature.

In order to have a check on the results of the retorting tests, however, a standard gas coal (Elkhorn) was run under the same conditions as the Ohio coals were run and also at the high temperatures commonly used in gas plants.

Several tests were made on each coal, but the results reported in this article are not the average results of the several tests. They are the results obtained on the tests when all conditions seemed to work for the highest accuracy.

Quality of Coke Obtained

The quantity and quality of coke obtained in these tests are probably an accurate index of the amounts and natures of the cokes from Ohio coals which will be obtained under commercial conditions, with this modifying statement: The coals shipped in for testing were mostly obtained at the worst period of depression in the mining industry in Ohio, and were dirty and poorly prepared because the normal operating procedures were not functioning at many of the mines from which samples were shipped. Hence the analyses of the ash in the coals and coke show abnormally high results for the coals from these regions. The results obtained on the washed coals are probably more nearly representative of the results which will be obtained on Ohio coals in commercial plants in the future, especially since the development of the very efficient machines for removing much of the ash and sulphur by dry-cleaning methods.

The writer used these cokes in a house-heating furnace last winter and found that they make splendid domestic furnace fuels, especially when mixed with about an equal weight of coal. Even when the coal mixed with the coke was of the smokiest type, a practically smokeless furnace was obtained when the coal and coke mixture was used. The coke when used alone tends to give too hot a fire unless there is a great deal of fine coke used. The author freely predicts that the future will see our cities no longer lying dirty and black under a pall of sooty smoke when the manufactured-gas plants which are bound to be erected about Ohio are selling coke regularly to consumers (perhaps under city ordinances) and householders burn a mixture of coal and coke or coke alone.

The tabulated results list the quality of the cokes under the symbols D, S, W and M, the meanings of which are:

D = Coke suitable for use in domestic furnaces.
S = Coke suitable for steam raising in power plants, etc.
W = Coke suitable for use in water-gas generators.
M = Coke suitable for use in blast furnaces or foundry cupolas.

It is our firm belief as a result of experience with these cokes that they will all be very useful for domestic heating. The only exceptions may be those cokes which come from coals having a large amount of fusible or "clinkery" ash, and these will be enormously improved by the use of dry cleaning or washing processes before the coal is retorted. Furthermore, it must be remembered that it is always possible to improve a coke by mixing a poor coke-making coal with a good coke-making coal.

All of the cokes made will be entirely satisfactory for steam purposes except those whose ash clinkers too readily. The ash of the Ohio coals and cokes are not more "clinkering" than those from other states. The cokes which are very friable would not do for locomotive use, because too much would be blown out, but the stronger cokes should be very satisfactory. The use of coke in the yard engines will do away with a great deal of the smoke nuisance.

For the manufacture of water gas the prime essentials are that the coke has as small an amount of ash as possible, that the ash has a high fusion temperature to prevent clinkering in the generator, that the coke has a high reactivity with water for the reaction $C + H_2O = CO + H_2$, and that the coke be not too friable, which would cause it to powder and blow out of the generator.

The qualities for a metallurgical coke are: Low ash, low sulphur, great strength and proper reactivity. The fusibility of the ash is of less moment.

Such properties as reactivity and strength of coke are difficult to measure and in the present preliminary survey time and funds have not been available for determining them. The results would not, moreover, have been satisfactory unless the cokes were made un-

*Part I was published in the issue of Dec. 13, 1922.

der the best conditions for each coal. Hence the classification of these cokes has been made entirely by inspection of the coke as it was heaped in a pile after being screened. All cokes were screened through a screen made of rods 1 in. apart, and the percentage that remained on the screen was taken as a measure of the strength of the coke. These screening results, the analysis of the coke, the fusibility of the ash and the appearance of the coke were used to classify the cokes, which means that the personal element of the

‡ Quality of coke.
M=metallurgical, W=water gas, D=domestic, S=steam, from a physical point f view, determined by inspection.
§ Total B.t.u. value given in thousands; thus, 3,642=3,642,000.

riter's judgment has entered into the classification nd hence no claim is made for infallibility in this lassification. Any coke which is good enough for ater-gas making or blast-furnace use will, of course, e excellent for domestic or steam purposes.

None of the cokes made in these tests were "stick-rs." That is, none of them swelled so as to jam in ie retort and fail to discharge easily when the dis-harge door was opened.

Properties of the Gas

The amount and quality of the gas obtained per ton f coal are very powerfully influenced by the condi-ons of retorting, particularly the temperature. In oke-making practice the temperature is lower and the mount of gas made is lower per ton of coal than in as retorts when the gas is the first consideration. For instance, at high temperatures the oxygen from coals tends to react with carbon, thus

$$C + H_2O = CO + H_2$$
$$C + 2H_2O = CO_2 + 2H_2$$

(the oxygen being largely liberated as water), and if all the oxygen should be so used the gas so made would be about 13,000 cu.ft. per ton of coal in addition to the hydrocarbons. At low temperatures the above reactions are very slow and most of the oxygen passes out as steam condensing in the cooling system. As previously mentioned, heating rates were more nearly like those used in coke-oven practice than gas-house practice, hence, these results for gas are probably somewhat low; at the same time low temperatures tend to be favorable to a high yield of light oils and tars.

The amount of sulphur in the gas combined as "organic sulphur" was in all cases far lower than the commonly accepted allowance of 30 grains per 100 cu.ft., even when the highest sulphur coals were used. Hence no fear on the score of sulphur in the gas from these coals need be had. Of course, the raw gas contains a large amount of H_2S, but since the advent of the "Seaboard process" for removing H_2S from gas and the improvement of other methods, the cost of the removal of H_2S is so low as to be but a very minor factor. It is quite possible, indeed, that the recovery of sulphur which is possible by the Seaboard process may turn high sulphur into an asset rather than a detriment.

We can, therefore, judge the value of our coals as gas-making coal solely on the basis of the value of the coke, B.t.u. in the gas, and the yield of ammonia, tar, light oils, etc., recoverable from a ton of coal.

Plotting the results of gas making against chemical analysis reveals no relationship, using as a base of comparison any of the items of either proximate or ultimate analysis. The reason is that the influence of varying retorting conditions is much more powerful than the influences of variation in chemical compositions in these coals.

Coals From Different Seams Compared

Coals from seams No. 4, 5, 6, 7 and 8 were included in the tests, and these were checked against Elkhorn coal and Smithers Creek No. 2 gas coal from West Virginia. The results from each seam were averaged to get the figures given in Table II. All results are for products obtained from 1 ton (2,000 lb.) of coal, except the determination of B.t.u., which is on the basis of a cu.ft. of gas.

In Table I test No. 21 shows the results obtained by

TABLE II—COMPARISON OF RESULTS OBTAINED WITH COALS FROM DIFFERENT SEAMS
(Yields per short ton of coal)

Seam	Smithers Creek No. 2 Gas	4	5	6	7	8	Elkhorn
Pounds of coke	1,300	1,245	1,370	1,260	1,257	1,302	1,280
Cu.ft. of gas	10,000	10,300	8,850	9,287	9,725	8,833	9,500
Av. gross B.t.u.	525	420	435	484	474	523	600
Total B.t.u.	5,250	4,326	3,850	4,477	4,605	4,627	5,700
Pounds of ammonia	4.8	4.5	4.32	5.00	5.1	...	...
Pounds of light oil	13	13	16	9.64	11	13.8	...
Pounds of tar	102	100	115	73.3	88.3	84.6	118

Only one sample of coal was obtained from each of No. 4 and No. 5 seams. However, when the best results obtained from each seam are compared the figures are:

Seam	Smithers Creek No. 2 Gas	4	5	6	7	8	Elkhorn
Pounds of coke	1,300	1,245	1,370	1,240	...	1,327	1,280
Cu.ft. of gas	10,000	10,300	8,850	12,000	11,000	9,200	9,500
Av. gross B.t.u.	525	420	435	475	470	535	600
Total B.t.u.	5,250	4,326	3,850	5,750	5,170	4,922	5,700
Pounds of ammonia	4.6	4.8	4.5	4.8	4.5	4.8	....
Pounds of light oil	15	13	16	13.5	...	23	...
Pounds of tar	100	102	115	73	83	82	118

retorting Elkhorn coal at higher temperatures, and from these it would seem probable that improved results would be also obtained by retorting Ohio coals at higher temperatures.

Summary of the Results

Coke—The coke obtained from the Ohio coals is equal in quantity to the coke obtained from recognized gas coals. Its quality for metallurgical purposes is decidedly inferior except when certain coals like Pocahontas is mixed with the Ohio coal before retorting. The cokes obtained from the Ohio coals are in general quite satisfactory for domestic heating. The more friable cokes could probably be made satisfactory by using a small proportion of Pocahontas or similar coal with the Ohio coal; the exact proportions will be determined by later tests. The ash in the cokes obtained in these tests is higher than is desirable, but this is largely due to the fact that the coals were obtained when the mines were not properly functioning. The fusibility temperature is in many cases satisfactorily high. Preliminary tests made in domestic furnaces would seem to indicate that these Ohio cokes will be satisfactory for domestic heating, which is by far the most important outlet for coke. When the coke is mixed with about its own weight of coal the mixture burns with a practically smokeless chimney.

Tar—The tar made is somewhat less in amount when Ohio coals are coked than when a standard gas coal like Elkhorn is coked, although in some cases the tar obtained from Ohio coals was practically as high as from Elkhorn. The value of the tars could not be compared, as time and funds for the complete analysis of the tars were not available.

Ammonia—The results obtained in these tests would indicate that the Ohio coals will yield about the same amount of ammonia as a standard gas coal (No. 2 gas or Elkhorn).

Light Oils—The amount of light oils obtained from the gasification of the Ohio coals is practically the same as that obtained from standard gas coal. However, the composition of the light oils was not investigated.

Gas—The volume of gas obtained by the gasification of Ohio coals at the temperatures used is about the same as that obtained from standard gas coals. The B.t.u. value of the gas from Ohio coals is considerably smaller than that obtained from Elkhorn, although nearly equal to that obtained from the No. 2 gas coal. This is especially true of the No. 8 coal. The total B.t.u. value of the gas from a ton of Ohio coal is in general lower than that from Elkhorn coal.

The impurities such as "organic sulphur" and naphthalene in the gas obtained from Ohio coals are satisfactorily low, being well within the ordinary legal requirements when the gas is made with vertical retort equipment. The large amount of H_2S in the gas before purification need not be regarded as a detriment. In fact, in some cases the recovery of the sulphur may produce revenue.

It is not claimed that Ohio coals are as satisfactory as the accepted standard gas coals for gas-making purposes. However, from all technical points of view Ohio coals can be satisfactorily used for gas and byproduct making, including the use of the coke for domestic purposes. If economic conditions, such as the cost of mining, freight rates, etc., are such that Ohio coals can be delivered to a gas plant at a lower price than other coals, it is quite possible that they may compete successfully for these purposes.

Since the work reported in these articles was completed new equipment has been added and the general arrangement has been changed as a result of the experience gained in the past year and a half. With these changes it will now be possible to obtain highly accurate data on the carbonization of the different coals. Using the results obtained in the present investigation as a basis for selecting the most promising types of Ohio coal, it is believed that it will be possible to arrive at an exact evaluation of these coals as compared with the standard gas coals of other states.

Some of the Frequently Met Errors in Cost Analysis

By W. A. Breen

MANY thousands of dollars are spent yearly in endeavoring to determine the cost of production, and this cost analysis is valuable for many purposes, among which are the pricing of inventory, the determination of selling prices and the checking of operating efficiency. For some purposes the absolute accuracy of cost is not relatively important, for if the same error is made on each of several operations or periods which are being compared, the errors will cancel out. However, this is not the case when costs are used to determine company policy. Can one style of product be produced more cheaply than another, or is it advisable to discontinue one line and concentrate on another? When such questions as these are to be answered it becomes of vital importance to determine the true cost. In large industrial plants with the many varied operations, it would often be prohibitively expensive to install recording devices which would be necessary to make a direct charge to each product of such expenses as steam, power, light, etc. Therefore, arbitrary methods of prorating certain direct expenses as well as the indirect or overhead expenses have been resorted to.

Traditions Should Be Viewed With Distrust

The writer wishes to express his strong distrust of traditions in cost analysis. He believes that there is always a better way to do a thing, the more especially if it has been done one way for a long time. A commonsense study of operating methods will bring this home to anyone who takes the trouble to analyze costs and cost data, provided he is willing to leave the beaten path of studying the finished cost of articles and examine operating procedure. It is a very frequent experience that a change of procedure looks to be profitable when the cost of a single product is considered, but ceases to be profitable if the true cost to the whole plant is evaluated.

For example, there was in a certain department a battery of four machines which produced rolls of material, and these were piled in storage by one man. It was decided that due to the design of one of the machines its product could be made more cheaply in another department where an idle machine could be utilized and would then turn out more goods per hour than the original unit. The change was made. However, they neglected to discharge one-quarter of a man who was used for removing the products of the four

machines to storage and the department in which this man worked had to distribute this quarter of a man over the three other machines. In the other department an additional quarter of a man was needed to remove the finished goods from the new machine and a whole man had to be hired to do this work. So the final cost to the company of this change of operation was nearly the cost of one man's wages, although a definite saving had been shown and was actually made on paper in so far as the operation of the machine itself went.

There is another excellent example which shows the necessity of computing the actual cost instead of using figures dependent upon arbitrary methods of prorating certain items. A plant in Chicago was receiving a viscous material in tank cars, some from St. Louis and some from New York. The price billed by the Eastern shipper allowed for the difference in freight between the two points, thus the purchasing department seemed justified in making the distribution. Steam, however, had to be used to heat up the material, in order that it could be made liquid enough to pump. These fuel charges had always been prorated to the different materials unloaded on a per gallon basis, and consequently the figures reflected the same cost in the storage for both materials. An actual test was made on the amount of steam consumed and it was found that due to the long trip from the Atlantic seaboard to Chicago the liquid became so viscous that $25 worth more steam per car was required to bring it to the stage sufficiently fluid to be pumped, and thus on only four cars per day a loss of nearly $30,000 a year was covered up by an arbitrary proration of these charges.

Example of Studying Actual Operating Conditions

For further illustration let us look at a paper mill. Here costs were found on different groups of products, each group being composed of several weights of paper and the cost of each being by actual test sufficiently close to justify a group figure. From the mill the paper was shipped to other mills to be impregnated with waterproofing liquid. This liquid, being cheaper than the paper, was used in excess so as to employ a maximum amount of saturant. At one mill a special machine was evolved which would accomplish this result, but it required more men to operate it. The extra labor cost was not great enough to offset the saving. Then came a labor shortage and wages began to rise and in a short time the new method was costing $2.40 per ton of paper more than was being saved by the additional saturant. Naturally, this fact indicated the desirability of scrapping the process. Before making this change, however, the investigator went to the paper mill and worked out an actual cost for the paper sent to the saturating mill. Here he found that because of the greater saturating ability of the altered machine, the paper made for it cost actually $5 per ton less, since cheaper ingredients could be used. As this paper was grouped in the cost system, however, with identical weight of stock shipped to other plants, the saving was not discovered until a study of the actual operating conditions was made.

Such examples are legion in which a different result can be obtained by going into the matter further than the immediate department or process in question, and it is frequently necessary to follow clear through to the profit obtained from the sale of the material. There is one case where it was found more costly to put a certain liquid into a heavy, expensive package than into a light one, and the question was discussed of charging more to the customer desiring this heavy package. Upon examining profits, however, it was found that the profit made on the heavy package was greater than on the light one, because the material sold as gross and more weight was actually bought for a given purpose.

Interest

Conventional cost finding does not include interest on money invested in buildings and equipment necessary to the manufacture of a product in considering cost of production, and there is some justice in not including it in the cost. When making a study of costs, however, it is well to consider it very much in the light of rent oftentimes. For example, how ridiculous it is to compare the cost of trucking by hired teams as against trucking with your own teams without including the interest on money invested in trucks and garage. Yet this very thing is being done every day by large corporations which are fooling themselves into thinking they are saving money. Still another example: Ten per cent earnings by two branches of a business. This figure came to be discussed at one time and it was found that if the branches were considered separately one branch paid 15 per cent while the other and larger half earned only 3½ per cent. In other words, the interest on the investment had not been considered. If it had, such a condition would have come to light years before.

These things seem so sufficiently obvious in relating them that one wonders why they are not immediately evident. It is partly due to the large amount of routine necessary in cost analysis work. Unless this routine is extended intelligently during expansion, absurd conditions arise such as the above illustrations. It is necessary to view cost methods with considerable common sense and to investigate operating conditions in connection with cost analysis. If the two do not go hand in hand, it is inevitable that confusion and erroneous conclusions will follow.

New York City.

Extraction of Precious Metals From Oil Shales

For a year or more statements have appeared in the technical press, and especially in various trade journals, indicating that valuable metals, such as gold, silver, platinum and other rare metals, have been found and also have been successfully extracted from oil shales. These reports stated that decarbonization and special methods of chlorination treatment, leaching and subsequent precipitation, also cyanidation followed by table concentration of the residues after cyanidation, all indicated that gold and silver and other metals could be and were successfully recovered.

Such articles have caused much misunderstanding, and as the correctness of some of the statements made in them has been questioned, an investigation of the subject was begun by the metallurgical division of the Bureau of Mines, in order, if possible, to determine to what extent, if any, metals of value do occur in oil shales, and if so, the feasibility of atempting their recovery by the processes said to have been used for that purpose.

Results of the Bureau of Mines investigations are given in Serial 2413, by Thomas Varley, superintendent of the Intermountain Experiment Station, Salt Lake City, Utah. This serial may be obtained by addressing the Bureau of Mines, Washington, D. C.

The Unique Development of Modern Chemical Stoneware*

An Account of the Progress Made During Recent Years in the Manufacture and Use of Chemical Stoneware—The Process of Manufacture, the Extending Uses, the Physical and Chemical Properties and the Probable Future of This Interesting and Useful Product

By Percy C. Kingsbury
Chief Engineer, General Ceramics Co., New York City

IT IS quite certain that the only material available for the first chemical experiments was clay ware molded to the desired shape and fired. Chemical ware may therefore be considered as dating from the beginnings of chemistry. As an industry, however, the manufacture of stoneware apparatus for chemical purposes is comparatively modern. The first plant devoted entirely to this industry was put into operation in 1836, although prior to this date several manufacturers of other clay products were making various shapes for the chemical industry as a side line, one manufacturer in Philadelphia having made chemical ware since 1816.

As might be expected, chemical ware has improved steadily in quality and workmanship during this time, although some of the ware made in Europe 50 years ago and which is still in service in this country bears very favorable comparison with much of the material sold today as chemical ware.

Early Products Limited by Potter

While there has been for many years a gradual improvement in the quality of this ware, it is only during the past 20 years or so that any serious effort has been made to manufacture anything except the simpler shapes. The chemical engineer of those days was compelled to design his plant to comprise only such shapes as the potter was willing or able to make. This is the reason for some of the inefficient apparatus seen around chemical plants today. A typical illustration of this is given in Fig. 1, which shows a vessel used for the absorption of hydrochloric acid gas in water. It is, as will be noted, a sphere flattened on the bottom. The purpose of the vessel is to offer a surface of contact between the gas and the absorbing liquid and to dissipate the heat of absorption by radiation from the exposed surface.

It will be observed that the path of the gas through the vessel is extremely short, the gas is not brought down near the surface of the liquid, but is free to short-circuit across the top of the vessel, the surface of contact between gas and liquid is very small compared with the floor space the vessel occupies, and as regards the removal of the heat of absorption by radiation, it is a well-known fact that the sphere is the shape having the smallest surface for a given volume, so that in this respect it would be a physical impossibility to devise a more inefficient vessel. I have no doubt, however, that every member present can recall many installations in which this shape is used today for the absorption of hydrochloric acid and also for the condensation of nitric acid.

This is only one instance out of many that could be cited to illustrate how, to a large extent, the potter decided what kind of chemical ware equipment should go into a chemical plant.

At that time the engineer had no choice, as the various other materials that have been developed during recent years with more or less success for handling acids and other corrosive liquids were not then available. He had to put up with the inconvenience and loss due to the shortcomings of the ware manufactured in those days. The inertia of popular opinion is such that some prejudice persists in the minds of a few chemical engineers today, notwithstanding the fact that the reason for it has long since ceased to exist. I may say, however, that this prejudice appears to be confined to this country.

Extent of Stoneware Industry

According to the report of the U. S. Geological Survey for 1920, which has the latest figures available, chemical stoneware is manufactured in New Jersey, Ohio, Pennsylvania, New York, Massachusetts, Iowa and California. The industry is, however, centered in New Jersey, one plant alone producing about 10 per cent more than the entire state of Ohio, which is the next most important producer. This New Jersey plant, which is the largest plant in the world devoted exclusively to the

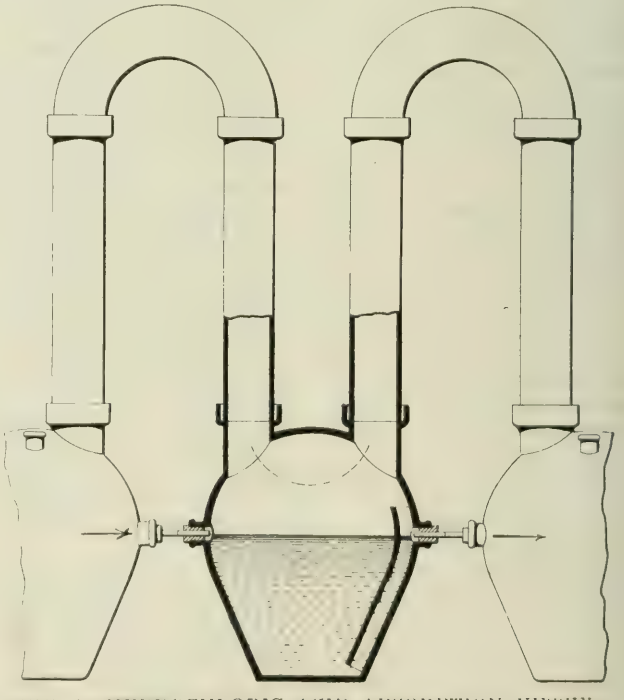

FIG. 1—HYDROCHLORIC ACID ABSORPTION VESSEL

*Paper presented at the Richmond meeting of the American Institute of Chemical Engineers, Dec. 7, 1922.

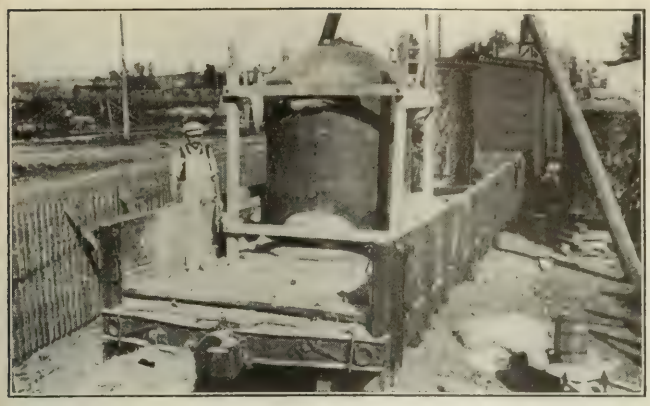

FIG. 2—1,200-GAL. ACID EGG

manufacture of chemical ware, produces as much as all the other plants in the United States put together.

What Is Chemical Stoneware?

Before considering the improvements that have been made in the chemical stoneware industry, let us first define this material.

Chemical stoneware may be considered as a skeleton or framework of more or less refractory particles held together by vitrifying clays. It is obvious that the physical properties of this ware can be modified within comparatively wide limits by variations in the raw materials used for this skeleton, in the degree of fineness to which these materials are ground and in the percentage employed in the mixture. At one extreme we have the coarse-grained chamotte bodies, which are of the nature of firebrick and which are used, for example, for conveying acid gases at a high temperature, as in a saltcake plant, where hydrochloric acid gas leaves the furnace at a temperature of 400 deg. C. or more. At the other extreme are the fine-grained porcelain-like bodies required for the large storage-battery tanks used in power plants and for electrolytic cells. An infinite gradation of products is of course possible between these two limits and the selection and preparation of a suitable material to meet some definite purpose require considerable judgment.

The Clay Must Have Special Properties

The clay which forms the vitreous bond between the particles must meet certain very specific requirements. It must vitrify at a definite temperature—i.e., the temperature of the kiln—this being adjusted by mixing it with definite proportions of other fluxing materials. It must be very plastic so that it may be molded into the many different shapes the potter is called upon to make. There must be a considerable difference in temperature between the vitrifying and the fusing points, as otherwise the shapes made from it will soften and collapse or at least deform in the kiln. It must have considerable mechanical strength in the green state so as to be able to support its own weight before firing when made up into large and often complicated forms. The shrinkage in drying and firing must be uniform, as otherwise it would be impossible for the potter to work to accurate dimensions, and the clay must be tough so as not to tear apart when subjected to the strain due to shrinking.

No natural clay will meet all these requirements, and it is necessary to mix several kinds of clay in order to obtain the desired results. Clays suitable for the highest grade of chemical ware are not widely distributed, and for many years we imported about 80 per cent of our clays from Germany, notwithstanding the fact that our plants are located in one of the greatest clay deposits in the United States.

Preparation and Aging of the Material

The various clays are mixed in the desired proportions, washed and screened to remove soluble and other foreign matter. The excess water is then removed by means of filter presses. The other components are then added and the mixture passed several times through a mill in which it is kneaded thoroughly until it is perfectly homogeneous. The mixture is extruded from the mill in large blocks, which are then stored away for 2 years in a saturated atmosphere. This has the effect of greatly increasing the plasticity of the clay, and for some of our work where great plasticity is necessary, the body is stored for 5 years. The nature of this so-called aging action is still a matter of controversy. The popular opinion seems to be that it is bacteriological. It is known that it can be induced and accelerated by the addition of certain organic products, but after some experimental work along these lines we no longer use these expedients. When the clay bodies are ready for use, they are made up into the various desired shapes, due allowance being made for shrinkage.

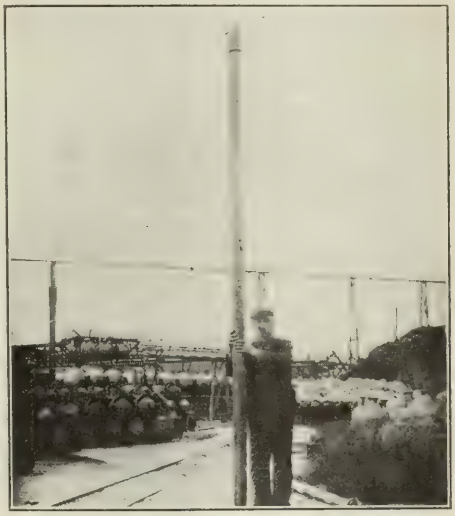

FIG. 3—STONEWARE PIPE

Plaster of paris molds are usually employed for this purpose, but many other methods are also used. Thus pipe and other cylindrical and prismatic shapes are extruded, some shapes are cast, a few shapes are turned up by hand and others are dry pressed. Where the quantities are large, as for instance in the case of carboy stoppers and Raschig rings for packing rectifying columns and scrubbing towers, elaborate automatic presses are used for this purpose.

Drying Must Be Carefully Controlled

After being shaped, the ware is dried. The most extraordinary precautions have to be taken at this stage of the manufacture. The shrinkage in drying is quite considerable, varying with the nature and moisture content of the body from 6 to 12 per cent linear. If the rate of drying of any particular shape is not uniform throughout, the uneven shrinkage causes deformation and often also internal stresses, the results of which are not apparent until after the manufacture is com-

pleted. In order to insure a uniform shrinkage at this stage, the drying has to be conducted very slowly or a drier must be used in which the temperature and moisture content of the atmosphere are under control. Where complicated shapes are to be made or where extreme accuracy in dimensions is desired, a drier of this type is indispensable.

Salt Added During the Firing

The dry ware is packed in large kilns, which are then bricked up and carried to a temperature of about 1,300 deg. C. Just before the maximum temperature is reached common salt is thrown into the fireholes. The salt volatilizes and the vapor reaches every part of the kiln. A surface reaction takes place between the salt and the aluminum silicate of the clay body, sodium-aluminum silicate being formed, and dense fumes of hydrochloric acid pass out through the stack. I shall refer to this and other methods of glazing later on. When the maximum temperature is reached the kiln is cooled down very slowly by radiation until the contents can be removed.

The time required for firing a kiln depends on its size and to some extent on the nature of the contents. Our largest kilns require 3 weeks for a cycle—3 days for setting and discharge, 4 days for heating and 13 days for cooling. This method of firing periodic kilns is extremely inefficient, practically all the heat being dissipated except a little that is used for drying green ware. For this reason we have recently installed at one of our plants a kiln divided up into chambers and furnished with an arrangement of flues so that the heat of the chambers that are cooling off is utilized for heating those that are going under fire.

In the open kilns referred to above the products of combustion come into direct contact with the ware. In this reducing atmosphere the traces of iron in the clay impart a bluish gray color to the body and a chocolate color to the glaze. In an oxidizing atmosphere the ware would be yellowish with a golden yellow glaze. White chemical ware, which is occasionally required for pharmaceutical and similar purposes, requires not only raw materials free from iron and other coloring matter but the ware must be fired in a muffle kiln, as the atmosphere in an open kiln contains volatilized iron, which would stain the ware.

After removal from the kiln, the ware is tested and sent to the grinding shop if any further finishing is required. The material is quite hard and carborundum is mostly used for this purpose, although less expensive materials, some of which are of our own manufacture, are also employed.

Many of the manufacturing processes referred to above and much of the mechanical equipment is of course common to most clayworking operations.

The raw materials used in this industry are acid proof within the usual limits for siliceous bodies, reference to which will be made later on, and they suffer practically no chemical change during the various manufacturing processes. There are, however, many problems of a physical nature met with in this class of work, the solution of which has to be acquired in the plant and laboratory, as there is little or no technical literature on this subject. It is not my intention this morning, however, to discuss our manufacturing problems, but to direct your attention to the progress that has been made within recent years in adapting this ware to the requirements of the chemical industry.

FIG. 4—FITTING FOR FUME DUCT

FIGS. 5 AND 6—SPECIAL STONEWARE TANK

Properties of Chemical Stoneware

The possibilities as well as the limitations of chemical ware are best shown by a consideration of the chemical and physical properties of this ware. A typical analysis of chemical stoneware is as follows:

COMPOSITION OF MIXTURE 57

	Per Cent		Per Cent
SiO_2	73.23	K_2O	2.02
Al_2O_3	22.27	Na_2O	1.42
Fe_2O_3	0.58	Loss on ignition	0.06
CaO	0.58		
MgO	Trace		100.16

This ware resists the action of all acids excepting only those which react with the silica—i.e., hydrofluoric acid and hot strong phosphoric acid. Concentrated solutions of the caustic alkalis when hot also have some action on it. This action is, however, not considerable and caustic alkalis may usually be handled to advantage in chemical ware. As might be expected, a stoneware that is high in alumina resists the action of caustic alkalis much better than one that is high in silica.

Glazes for Chemical Ware

Chemical stoneware is usually glazed, the glaze, however, being merely a finish to give a smooth surface to the ware and not for the purpose of adding to the acid-resisting properties. As a matter of fact, the glaze is less resistant to chemical action than the body, and for this reason we are occasionally called upon to furnish unglazed ware. Under these circumstances a very dense body must naturally be employed. Some ware is manufactured for chemical purposes having a more or less porous body that depends for its acid-resisting properties on a heavy coating of a prepared

glaze applied before firing by means of a brush or spray or by dipping. These glazes may be considered as clays with a low melting point which fuse in the kiln to a more or less homogeneous layer at the temperature of vitrification of the body. Such ware can scarcely be considered as chemical stoneware, as it offers no advantage over the various materials on the market coated with so-called acid-proof paints, varnishes and enamels which become valueless as soon as there is the slightest imperfection in the exposed surface. There can be no question that salt glaze is much to be preferred for chemical work. A composition of this glaze is roughly as follows:

SiO_2	66.80	Na_2O	12.55
Al_2O_3	20.65		
			100.00

It is a sodium-aluminum silicate—i.e., a glass intermolecularly combined with the body so that it cannot craze nor peel.

Physical Characteristics

The physical characteristics of chemical stoneware are given in the following table:

Tensile strength, lb. per sq.in.	1,000-2,200
Compressive strength, lb. per sq in	25,000
Modulus of elasticity, lb.	6,000,000-9,000,000
Thermal conductivity, B.t.u.	0.55-0.6
Specific heat	0.2
Specific gravity	2.17
Coefficient of expansion (linear per deg. C.)	0.000003-0.000005

These are, of course, average values, as the physical properties vary considerably with different grades of

FIG. 7—CONDENSATION COIL

ware. This is particularly true of the tensile strength. Thus the body we use for acid pipe lines has a tensile strength of 1,000 lb. per square inch, the body used for electrolytic work has a value of 1,700 lb. per square inch and the bodies used for pump and exhaust fan impellers and for blowcases are much higher. We have tested an 18-in. impeller to 4,500 r.p.m. without bursting it—i.e., a peripheral speed of over 21,000 ft. per minute.

Attempts are frequently made to modify the physical properties of chemical ware by the addition of materials such as carborundum, various refractory oxides, etc. These products are placed on the market from time to time under fancy trade names and extravagant claims are made for them which have seldom been justified. This, however, opens a fertile field for the future development of this industry.

Practically any shape that can be made in metal or any other structural material can be duplicated in stoneware if due consideration is given to the physical properties of this ware. The accompanying pictures will

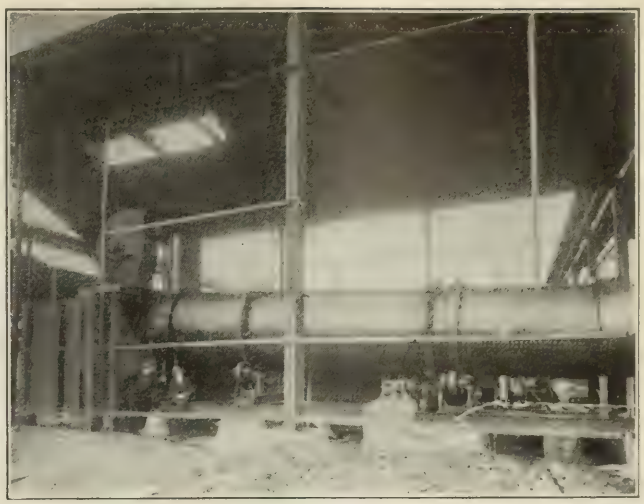

FIG. 8—ROTARY DRIER

illustrate the possibilities that chemical ware offers to the chemical industry. In line with the general trend toward large-scale production we have been called upon to furnish equipment in as large units as possible. There is naturally a limit to the size to which clay ware can be made, but Fig. 2 shows a remarkably large vessel—undoubtedly the largest made in this country. It is the body of an acid egg or blowcase and was used for forcing a sludge into a filter press by means of compressed air at a pressure of 50 lb. per square inch. The vessel, which has a capacity of 1,200 gal., was of course protected by a steel shell on the outside. The sludge in this case was formed by treating carnotite residues with muriatic acid in the extraction of radium. Still larger shapes have been made in Europe, a 1,500-gal. vessel having been exhibited at a recent exposition in Dresden. The filter presses used in connection with the blowcase referred to were the usual wooden plate and frame presses. We designed and installed this equipment several years ago. It is interesting to record that we have now succeeded in making these filter presses also out of stoneware.

Fig. 3 shows a 4-in. pipe about 14 ft. long. One end is closed, the other end is open and has a branch near the top with a flange under it. These tubes are used for cooling hydrochloric acid gas from about 80 deg. C. to about 15 deg. C. in the following manner: A stoneware tower has a perforated plate on top and twenty-six of these tubes hang in the tower supported by their

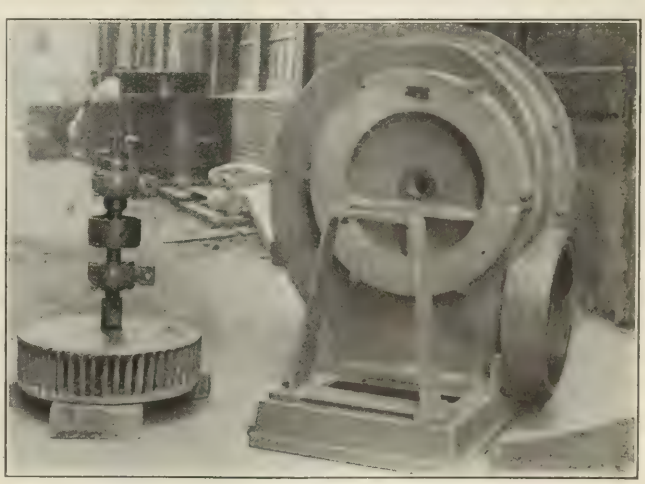

FIG. 9—LARGE EXHAUST FAN

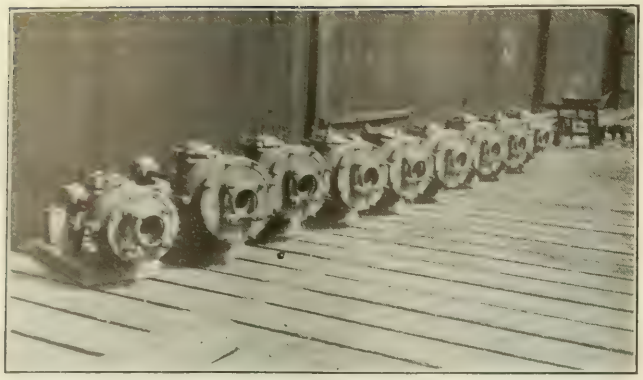

FIG. 10—STONEWARE PUMPS

flange on the perforated plate. Each tube is cooled by water which is carried to the bottom by a pipe and which overflows through the branch at the top. I will show you presently a picture of the complete plant in which this device is used. The idea is adapted to all kinds of purposes in the chemical industry, but the tubes are not usually so long as in this case.

Fig. 4 shows part of a 48-in. diameter fume duct we manufactured a few years ago. This particular fitting is about 8 ft. high.

Fig. 5 is a tank we made during the war for the manufacture of radiators for airplane engines by electrodeposition of copper. I want you to note how accurately the slots match up. You will see it better perhaps in Fig. 6.

A stoneware coil (Fig. 7) usually impresses one not familiar with the manufacture of clay products. Given the right kind of body, however, they are not difficult to manufacture and will stand a remarkable amount of rough handling. The most usual size has a $2\frac{1}{2}$-in. tube with a wall $\frac{3}{16}$ in. thick and 80 ft. long. It is wound on a stoneware drum, but is not attached to it, so that the tube is free to expand and contract with change in temperature. We have shipped these coils all over the world. They are used principally for the condensation of nitric acid, for which they are ideal. They are also made as shown in the picture for cooling corrosive liquids. You will note that one of these coils has a corrugated cross-section for the purpose of increasing the cooling surface of the tube.

Fig. 8 shows a rotary drier with a cylinder about 20 ft. long. The entire cylinder was made of chemical stoneware and the flights were made integral with it. The feeding head was also of stoneware, as shown in the picture. The material to be dried was saturated with muriatic acid and every part of the machine coming in contact either with the moist material or the vapor had to be made of stoneware. The vapors were drawn off by a stoneware fan and condensed in stoneware towers.

A stoneware exhaust fan similar to that referred to above is shown in Fig. 9. This is the largest size we make to this design and will handle about 6,000 cu.ft.

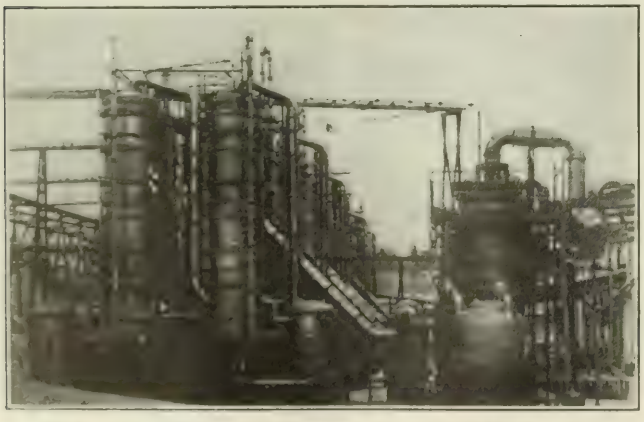

FIG. 11—MURIATIC ACID PLANT, ALL STONEWARE

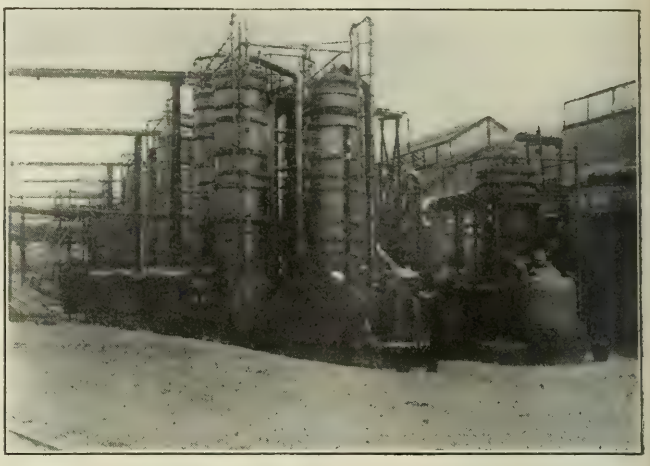

FIG. 12—ANOTHER VIEW OF MURIATIC ACID PLANT

per minute. We furnished a very large number of these machines during the war for handling the oxides of nitrogen evolved from nitrating operations. The body and impeller—in fact every part coming in contact with the gas—are made of chemical stoneware. I scarcely need say that a very high-grade body is required for this class of work. The impeller shown in the picture is tested to 1,500 r.p.m. The smaller sizes are tested to 3,000 r.p.m.

Stoneware pumps (Fig. 10) are used for innumerable purposes around chemical plants and for handling every imaginable kind of corrosive liquid. They are also used largely for handling food products such as soup and vinegar, as they can be kept perfectly clean.

If stoneware chemical plant is to be thoroughly satisfactory, it must be carefully erected, and we therefore endeavor to use our own experienced men for this work wherever possible, whether the plant has been designed by ourselves or by our customers or their engineers.

Fig. 11 is a muriatic acid plant. This is the plant in which were used those 4-in. pipes 14 ft. long shown in Fig. 3. I want you to note that this plant has no protection whatsoever from the weather. The hydrochloric acid gas enters the pipe line at about 250 deg. C. and reaches the first tower at about 80 deg. C. The entire equipment is subject to zero temperature in winter and also to wind and snow and rain, but it has given no trouble whatsoever.

The Future of Chemical Stoneware

I have endeavored so far to show what has been accomplished in stoneware equipment for the chemical industry, and in conclusion would like to say a few words as to the future of this industry.

An important fact to be borne in mind is that although chemical stoneware is undoubtedly the best material for chemical plants handling corrosive products, yet it is no longer absolutely indispensable except in a few particular cases. No material has the general

utility of stoneware, but for any specific purpose there is some other material that can be substituted for it except in a few special instances. In practically every case these substitutes have no advantage over chemical stoneware—in many cases they have very distinct disadvantages and they are almost invariably much more expensive. Every few weeks one or more of these new products is brought to our attention and most of them die a natural death after the usual comparative tests have been made, and this situation has acted as a stimulus to the chemical ware industry.

The production of chemical stoneware in the U. S. in 1920 increased 54 per cent over the 1919 production and when the figures for 1922 are available they will undoubtedly show a still further steady increase. This is concrete evidence of the confidence of the chemical industry in American-made chemical ware which the manufacturer can easily retain if he will continue to improve his product and will base his sales propaganda on definite demonstrable facts and accurate data rather than on extravagant general statements and so-called "talking points."

Wooden Barrels for Chemicals

Summary of Proper Use by Which User May Choose Type Best Suited to His Industry

THE Associated Cooperage Industries of America, which is the trade association of the barrel manufacturers, has recently issued a booklet entitled "Slack Barrels for Chemicals," which calls attention to the wide use of barrels for containers in chemical and allied industries. This booklet gives a good summary of the proper uses of the slack barrel, and, when combined with other summaries furnished by this association, is of sufficient interest to engineers to warrant reproduction here. These summaries follow:

The cooperage industry has devoted some time and thought to the subject of improving barrel service to the chemical and allied trades, particularly with reference to the specific commodity and the principles of packing. With a proper knowledge of these, it is a comparatively simple problem to decide upon the kind of barrel best suited for shipping various chemicals.

From the scientific and technical point of view, standards of measurement, standards of performance and standards of quality have been established by the Bureau of Standards, Washington, D. C., covering barrels for certain food products and other commodities. Inasmuch, however, as the chemical and cooperage manufacturers have not so far developed a certain rule of measure for chemical containers, the chemical industry accepts wood barrels by contract specifications. Barrels used at the present time for shipment of chemicals are known as "slack," "semi-tight" and "tight."

The following outline is designed to give an idea of the proper kind of barrels required for use in chemical industry. It does not pretend to cover barrel use in detail, but merely discusses the basic operations which are common to the entire industry. The chemical products listed will not therefore be a complete directory of what the wooden barrel is capable of carrying:

Slack Barrels

The slack barrel is an ideal container for shipping chemicals which are not efflorescent, also for compounds and materials, varying in weight from 50 to 500 lb.

Products Shipped—Ammonium picrate, asphalt, cement, dry chemicals, lime, arsenate, paint pigments, picric acid, compounds, dye materials, glass, crockery, brick, clay, terra cotta, etc.

Appreciating the fact that there is considerable variation in the density of chemicals and in the manner of their preparation for shipment, the need for careful specification is apparent when making estimates as to the most efficient utilization of wood barrels. The slack cooperage industry has established a code of grade rules and specifications applicable to use of various timbers. Gum, elm, cottonwood, basswood, oak, beech, maple, etc., are used and graded as No. 1, millrun and No. 2. Coiled elm hoops are also of standard quality and dimensions. Wire and steel hoops used by specification.

Specifications for slack barrels most commonly used in chemical industry are as follows:

13½ in. head	20 in. staves
16½ in. head	24 in. staves
17⅝ in. head	28½ in. staves
19⅝ in. head	30 in. staves

Slack casks for crockery and glass 24 to 48 in. head, 34 to 42 in. staves.

"Tongued and Grooved" Slack Barrel

To provide a practical, efficient and economical container that would adequately fill the requirements of the chemical industry for the shipment of efflorescent and semi-liquid products, the slack cooperage industry has evolved what is known as a "tongued and grooved" slack barrel. This package is made from staves ⅜ in. thick, heading ⅝ in. glued; silicated when found necessary.

The staves being tongued and grooved and heading glued, a practically water and air tight package is provided. Gallonage capacity is usually referred to when ordering this kind of container. The dimensions are as follows:

17⅛ in. head, 30 in. staves	for 30 to 32 gal. size
20 in. head, 34 in. staves	for 45 gal. size
21 in. head, 34 in. staves	for 50 gal. size
22 in. head, 34 in. staves	for 55 to 57 gal. size

Tight Barrels

Products Shipped — Chemicals, alcohol, beverages, compounds, cider, dyes and colors, solutions, extracts, grease, oils, food products, glue, paint, varnish, polish, sirup, molasses, vinegar, etc.

The "tight" barrel, as the name implies, is used for the shipment of liquid and semi-liquid chemicals. Laboratory tests have been made to obtain a better knowledge of the action of acids and chemicals on wood barrels; when necessary, silicate, paraffine and glue are used as liners. Rough usage tests have been applied to determine a definite understanding as to quality, grade, specification and standards of timber for tight barrel construction. White oak, red oak, ash and fir are used, and steel hoops of standard gage. Sizes range from 5 to 60 gal. capacity, according to specifications.

It is evident from the above that the user of barrels can well pick out for himself the type of barrel he desires; but in purchasing, in order to realize the full value of the studies made by the Associated Cooperage Industries of America, a careful specification of the service which the barrel is to perform should be furnished to the barrel manufacturer.

The Glass Industry in Poland

The glass industry in Poland is mainly organized by the Union of Glass Works. Forty-six establishments belong to this union having at present seventy furnaces working and employing about 10,000 workers. Thirty-five smaller glass works are not affiliated with the union; the total number is thus eighty-one, employing more than 12,000 workers. The annual production may be computed at about 102,000 tons a year. This quantity not only provides for national needs but leaves a surplus of 40 per cent for export. The principal foreign market for Polish glass is Rumania.

In 1921 Polish glassworks exported only about a thousand tons; on the other hand, glass goods were imported to the extent of 7,300 tons. Now, however, exports are increasing and imports are decreasing; imports still include mirrors, optical glasses, watch glasses and certain categories of glass for technical apparatus.

The Polish glass industry flourishes especially in what was formerly Russian Poland, as the Polish market before the war was largely Russia. It bids fair to become an important export industry.

Recent Chemical & Metallurgical Patents

Process of Filtering Vapors — A patent has been granted to Willett C. and Frank E. Wells, of Columbus, Ohio, for an apparatus and process of filtering vapors such as those given off during the process of distilling petroleum oil. The invention is a process of filtering the vapors of hydrocarbons evolved by passing a permanent neutral gas through the heated oil and this with its load of vapor up through filtering material such as fullers earth for the purpose of removing color and bituminous matter, and then to a condenser where the distillates are recovered. As the filtering material receives its heat solely from the gas and vapor passing through it, it is necessarily of lower temperature than the fluid which heats it. Consequently, a portion of the less volatile vapors condense in the filtering material, and this condensate is absorbed and retained until the continuously increasing temperature of the succeeding vapor evaporates it. In so doing it continuously deposits more condensate of less volatility in its stead, thus very materially narrowing the volatility range of any portion of the distillate. (1,433,050. Oct. 24, 1922.)

A New Titanium Pigment—In a previous patent (No. 1,348,129, granted July 27, 1920) V. M. Goldschmidt, assignor to the Titan Company, of Christiania, Norway, described a material for use as a pigment comprising a more or less crystalline titanium oxide. In a more recent patent he describes a titanium pigment in which all or part of the titanium is present in the form of a titanate. The specific source referred to is the calcium titanate, although acid, normal and basic titanates of other bivalent metals are included in his specification. These pigments, he claims, are insoluble or sparingly soluble in water, and are very stable against both oxidation and reduction. Accordingly they resist the action of both the atmosphere and vehicle. The titanium compounds contained in the pigment have high specific gravity and high refractive index, thereby giving the pigment great hiding power. The normal calcium titanate ($CaTiO_3$), which combines great stability with a high refractive index (2.4 in sodium light), may be prepared in the following manner: Ilmenite is treated with sulphuric acid and after the resulting sulphate mass in lixiviated, the titanic acid is precipitated from the resulting solution. This product, which will usually contain a quantity of the SO_4 radical, is then mixed with slightly more than an equivalent of lime and the mixture is heated to a sufficiently high temperature to cause the formation of calcium titanate, preferably in a crystalline condition. The resulting product is of a white or yellowish-white color and is said to be an excellent pigment. The titanates and their double salts give white pigments when the bases of the salts are colorless, and different colors when the bases are colored. (1,436,164. Nov. 21, 1922.)

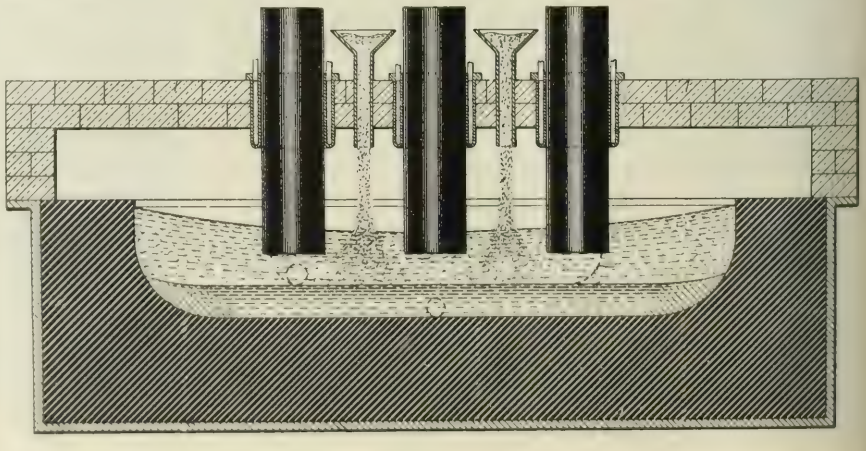
American Patents
Issued Dec. 5, 1922

The following numbers have been selected from the latest available issue of the *Official Gazette* of the United States Patent Office because they appear to have pertinent interest for *Chem. & Met.* readers. They will be studied later by *Chem. & Met.'s* staff, and those which, in our judgment, are most worthy will be published in abstract. It is recognized that we cannot always anticipate our readers' interests, and accordingly this advance list is published for the benefit of those who may not care to await our judgment and synopsis.

1,437,394—Purification of Phenol Contaminated Liquors.
1,437,401—Purification of Phenol Contaminated Liquors.
1,437,405—Treating Molten Metal.
1,437,483—Production of Aldehydes.
1,437,636—Chlorinating Organic Compounds.
1,437,689—Separation of Petroleum.
1,437,743—Extraction of Oil.
1,437,769—Duplex Tunnel Kiln.
1,437,775—Fusible Combustibles.
1,437,783—Condensation Product.
1,437,801—Sugar Extraction.
1,437,838—Soluble Lime-Sulphur Composition.
1,437,932—Treating Hydrocarbons.
1,437,933—Treating Hydrocarbons.
1,437,952—Plastic Compositions.
1,437,980—Distillation Process.
1,438,123—Process of Making Alcohols.

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Production of Ferrovanadium—B. D. Saklatwalla and A. N. Anderson have patented a method for reducing refractory oxides with carbon in an electric furnace. The accompanying illustration shows, to scale, the principal lines of their preferred furnace. Current must be led in at not less than 150 volts and 35 amperes per sq.in. of electrode cross-section; the electrodes must be correctly spaced and immersed in the slag bath; and the cold charge must be fed between the electrodes, falling directly into the hottest portion of the furnace with little or no preheating. In this way direct reduction of the refractory (vanadium) oxide is quickly effected by the carbon without the formation of lower oxides on intermediate compounds—a circumstance found highly desirable. The charge consists of ore, iron scale, coke and fluxes (glass cullet, lime and fluorspar). Glass cullet and iron oxide are of advantage in that they increasse the electrical resistance of the slag, and the former also decreases its swirling motion by increasing its viscosity. This swirling motion draws the cold charge into the best region for quick reduction, and a 50 per cent ferrovanadium has thus been made. (1,435,742 Nov. 14, 1922. Assigned to Vanadium Corporation of America.)



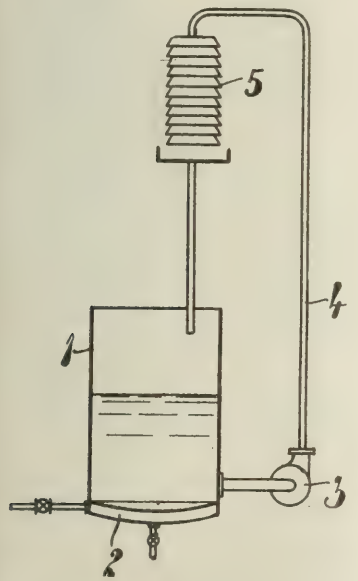
Iron-Free Nitric Acid—An apparatus for the concentration and purification of nitric acid is described in a specification taken out by George H. Tozier of Rochester, N. Y., and assigned to the Eastman Kodak Co. It is particularly designed to remove traces of iron from commercial nitric acid. The principle of the process is the insertion of a reflux condenser in the vapor line from a Duriron nitric acid still. The still is steam jacketed and the vapors from the boiling weak nitric acid are conducted through a vertical line to a reflux condenser, which is made of Pyrex glass or fused quartz. This condenser is also steam jacketed. The theory is that the iron is mechanically carried over by the particles of nitric acid coming out of the still, and the condensation which takes place in the reflux condenser serves to wash the ascending vapors and to carry the impurities back into the still. The temperature in the jacket of the condenser is maintained at a point low enough to bring out sufficient condensation to remove all the objectionable impurities.

From the reflux condenser the vapors pass through an ordinary water-cooled tube condenser. The tubes are preferably made of Pyrex or fused quartz. The condensate runs from this con-

denser into bleachers, where air is blown through the acid to remove nitrogen oxides and any chlorine, bromine or other gaseous impurities. (1,529,177. Sept. 12, 1922.)

Chlorinating Paraffine Hydrocarbons—The patentee has found that by causing the liquid hydrocarbons of the paraffine series to react with chlorine gas under the influence of actinic rays and in the presence of an absorbent such as silica gel, activated carbon or pumice in a finely divided condition as a catalyzer, and passing the hydrocarbon and chlorine through successive quantities of such absorbent, the reaction can be made to proceed more smoothly and regularly and quickly, and the resulting production of chlorohydrocarbons can be made more definite in character and amount. It has also been found that the reaction can be further hastened and improved by impregnating the finely divided absorbent with metals or metallic compounds. (George T. Koch, of Homer, Ohio, assignor to the Ohio Fuel Supply Co., Pittsburgh, Pa. Oct. 24, 1922.)

Transformation of Cyanamide Into Urea—J. H. Lidholm, of Sweden, has patented a method for transforming cyanamide into urea. The trouble with the present method is that when carried out at 65 deg., at which temperature the reaction of cyanamide plus water gives urea, the rate of reaction is so rapid that it is difficult to keep the



temperature constant. To do this an apparatus is suggested. In the figure, 1 is an open container having a steam jacket 2 at the bottom or other equivalent means for heating the content of the container. A pump 3 circulates the content of the container through the pipe 4 up to a cooling tower 5, from which it again flows down into the container 1.

In carrying out the process in the apparatus described the cyanamide solution is introduced into the container 1 and sulphuric acid is added in such quantity that the solution becomes about 1-normal with respect to the acid. The solution is then heated by supplying steam to the jacket 2 of the container so that the temperature will rise to about 65 deg. C. When the reaction has started and the temptrature begins to rise, the solution is continuously pumped up to the cooling tower, where a part of the water of the solution is evaporated and carried away by the atmospheric air, the evaporation causing a cooling of the solution, which then flows back to the container. In this manner the reaction temperature may be kept practically constant during the operation and the heat evolved by the reaction utilized for a partial concentration of the solution. (1,436,180. Nov. 21, 1922.)

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Motor Fuel—A fuel for internal combustion engines comprises a solution of water in benzol and acetone. Ethyl or methyl alcohol and ether may be added. The water should comprise 8 to 16 per cent of the liquid. The preferred composition consists of 60 lb. of ethyl alcohol, 20 lb. of acetone, 10 lb. of benzol or benzene, and 10 lb. of water. (Br. Pat. 183,577. H. R. Ricardo, London. Sept. 20, 1922.)

Cellulose Products—A cellulose product adapted for the manufacture of viscose and termed hydra-oxycellulose is prepared by treating cellulose admixed with water first with gaseous chlorine in excess of the amount required to saturate the water present, and afterward with strong hydrochloric acid, preferably the acid produced in the first stage of the process and which is brought into action by drying the moist product—for example, by heating at 60 deg. C.—until a brittle product results. The proportions of water and chlorine to be observed in the case of wood pulp are: cellulose 100 parts, water 100 parts, chlorine 10 parts; in other cases a larger proportion of chlorine may be necessary—for instance, with oat straw, 30 to 50 parts of chlorine for every 100 parts of cellulose would be required—in any case the proportion of water lies between one-half and twice the weight of the cellulose material. By subjection to the usual xanthogenation process, the cellulose conversion product is converted into a viscose which at the usual concentrations has the character of a jelly. The viscose solution is adapted for the manufacture of artificial silk, paper size, leather board, etc.; and it may be mixed with materials such as zinc, chromic and ferric oxides, clay, starchy matters, paper pulp, dissolved resins, esparto rosin, fats, waxes, glycerine, shellac, dyes and pigments; and in most cases such addition would be added before the preparation of the viscose solution. According to the material added, substitutes for horn, bone, ivory, ebonite, wood, celluloid, leather and india rubber are obtained. When used for the manufacture of solid bodies, the solution is poured into molds and permitted to stand to separate air bubbles—this separation is facilitated by pouring a thin film of water on to the surface—and the mold then heated to 40 deg. C. for some hours; a compact mass capable of being manipulated is thus obtained, which is subsequently washed with warm water and dried, or heated to 100 deg. C., to render it, or an article made therefrom, impervious to water. Of the materials specified that may be incorporated with the product, zinc oxide and ferric oxide are particularly useful; with the former, the product may be bleached by calcium or sodium hydrochlorite or may be dyed, the dyes being applied previous to coagulation or after washing and before drying. Pigments such as ultramarine may be added. The viscose material, if impregnated with glycerine before coagulation or after washing the coagulated material, gives a coagulated mass of the consistency of india rubber or of leather; a good imitation of leather is prepared by adding zinc oxide and resin oil and afterward impregnating with glycerine. Omitting the glycerine, the material is suitable for buttons, door knobs, etc. The viscose material may also be used as a bond for abrasives in making grindstones, hones, emery cloth, polishing sheets, knife boards and razor strops. (Br. Pat. 184,610. C. C. L. G. Budde, Sunderland. Oct. 11, 1922.)

Cellulose Acetate—Cyclobutanone or side chain homologs thereof, such as dimethyl- or diethylcyclobutanone, is employed as a solvent for cellulose acetates in the manufacture of solutions, plastic masses, artificial silk, films, etc. The solvents, diluents, filling substances, coloring matter, etc., may be added in addition. Examples of proportions are given in the specification. (Br. Pat. 184,671. H. Dreyfus, London. Oct. 11, 1922.)

Purifying Acetylene—To the alkali hypochlorite solution used for removing phosphine and H_2S from acetylene is added a substance such as alkali bicarbonate that prevents the solution from containing any considerable concentration of free hypochlorous acid. When exhausted, the purifying solution is regenerated electrolytically, preferably with the use of graphite anodes and an addition of potassium chromate. (Br. Pat. 184,778; not yet accepted. Elektrizitätswerk Lonza, Basel. Oct. 11, 1922.)

Motor Fuel—A fuel for internal combustion engines consists of a mixture of a hydronaphthalene, an aliphatic hydrocarbon of low boiling point, and methylated spirit, blended by a small proportion of ether or an alcohol of high boiling point. In an example, 30 parts of tetrahydronaphthalene, 35 parts of petrol or light petroleum and 30 parts of methylated spirits are blended by 5 parts of amyl alcohol. (Br. Pat. 184,785. Riedel Akt.-Ges., Berlin. Oct. 11, 1922.)

Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Arsenic Situation Clarified by Conference Between Producers and Users

Meeting Held to Investigate Present Shortage Evaluates Existing Stocks, Trade and Agricultural Requirements and the Possibilities of Increased Production

PRODUCERS of arsenic, manufacturers of arsenical insecticides, glass makers and other users of arsenic met at the Hotel Astor, New York, Dec. 13, to give sober study to the arsenic situation and if possible to unearth a supply of calcium arsenate sufficient to provide for next year's campaign against the boll weevil.

The meeting was called by C. R. DeLong, of the U. S. Tariff Commission and former chief of the chemical division of the Department of Commerce, and was one of the features of the annual convention of the Insecticide and Disinfectant Manufacturers' Association. Although the meeting had nothing to do with the pending Congressional resolutions for investigation of the arsenic industry, all angles of the present situation were discussed by men who were thoroughly informed of developments in the different branches of the trade.

Dr. R. B. Coad, Southern field agent for the Bureau of Entomology of the Department of Agriculture, presented an accurate analysis of the problem from the cotton farmer's viewpoint. Hamilton M. Brush, manager of the sales department of the American Smelting & Refining Co., and F. Y. Robertson, vice-president of the United States Smelting & Refining Co., reported for the arsenic producers. Frank Hemingway, of the Sherwin-Williams Co., former State Senator George F. Thompson, of the Niagara Spray Co., O. A. Hasse, vice-president of the Glidden Co., and R. N. Chipman, of the Chipman Chemical Engineering Co., were some of the insecticide manufacturers who contributed to the discussion.

Arsenic Requirements

Naturally the discussion largely centered around calcium arsenate, the poison that has been found most effective in combating the Mexican boll weevil. According to Dr. Coad, of the Department of Agriculture, approximately 16,000,000 lb. of calcium arsenate was sold in the South last season and there was a demand for more than that amount. On the whole, the results from calcium arsenate were good, he declared, and while in the outlook for next season the price of calcium arsenate and the price of cotton will be factors in the situation, it looks, nevertheless, as if the demand would run far ahead of the supply.

In an attempt to figure the minimum requirements of arsenic for purposes other than calcium arsenate, the following figures were worked out for refined white arsenic:

	Tons
Arsenate of lead	2,000
Paris green	1,200
Proprietary mixtures	750
Sheep dips	1,000
Weed killers	1,500
Glass	2,000
	8,450

On this basis, Dr. Coad said, there is barely enough arsenic in sight to meet requirements, leaving calcium arsenate out of consideration entirely. Last year the production of calcium arsenate used nearly 4,000 tons of arsenic and next year, it is estimated, there will be a demand for not less than three times last season's requirements.

What Can the Farmer Pay?

Discussing the price the cotton farmer would be willing to pay for calcium arsenate, Dr. Coad said that the sale of calcium arsenate in the South is no longer a pioneering proposition, and that the farmer knows now how much he can pay for it and still make a profit on his crop.

After a great deal of investigating, the department has arrived at the conclusion that the farmer should be able to trade a pound of lint cotton for a pound of calcium arsenate; that, moreover, the price of calcium arsenate should be figured on the basis of the probable price of cotton next fall. If, for instance, cotton should sell at 18 or 20 cents, the farmer should not have to pay more than 18 or 20 cents for calcium arsenate delivered on his farm. Allowing a spread of 4 cents for distribution in the South, Dr. Coad said, would drop the price back to 14 cents. The question is, he continued, how much can the insecticide manufacturer afford to pay for arsenic in order to make calcium arsenate? No manufacturer, he declared, can afford to pay over 10

How the Bureau of Standards Holds Its Techincal Employees

The general impression regarding government salaries is that they are very inadequate, failing to attract the better class of techncial men, especially under present conditions. A recent statement by F. C. Brown, assistant director of the Bureau of Standards, is, therefore, of considerable interest:

> There have been in the twenty-one years a total of 574 college graduates who have entered the Bureau of Standards and who later left. On the average these men remained at the bureau for 2.5 years for what we would like to term a graduate course of training. During their stay at the bureau they received an average increase in salary of $133 per year. There were, of course, among these men many who found themselves in the wrong place, but probably one-half of this number left the bureau merely because of special opportunities opened to them, with anywhere from 50 to 200 per cent increases in salary. The Bureau of Standards employees are tempted away for two reasons, first, because they have the bureau's stamp on them, and second, because of the special training they get here.
>
> With regard to the college graduates who have come to the Bureau of Standards and who have remained, I would state that in general these have been the ones who have found themselves suited to the work and happy in it. At present we have 330 employees who have come to us either as college graduates or who have finished their college work while engaged here. Of this number 60 have the Ph.D. degree. About 22 of our employees have obtained the doctor's degree while working here, and a number have other advanced degrees. Among these men the average entrance salary has been with the bureau on the average of 4.7 years each, and their average salary at present is $2,348. This group has therefore received an annual increase averaging $180. Almost all of these individuals have had many opportunities to leave the bureau at large increases in salary. They have felt the spirit of the institution and have been conscious of the part they are playing. Aside from this, many of them keenly appreciate the variety of opportunities that the national capital offers.

Dr. Brown's statement is accompanied by a chart showing the distribution of salaries among the 536 technical employees of the bureau.

Annual Reports of Government Laboratories

Bureau of Standards Has Devoted Efforts Toward Standardization and Elimination of Waste

THE most important efforts of the Bureau of Standards during the past year were those directed toward the elimination of waste, says the annual report of the bureau.

A complete study of automobile engine performance, both in the laboratory and in cars on the road, is being carried out with the object of increasing the efficiency of internal-combustion engines. If the bureau, through this work, can assist in lowering the gasoline consumption of automobiles only 10 per cent for given mileage, it will represent a saving to the country of something like $100,000,000 per year.

Varied Research Problems

Large sums are lost each year through the corrosion of underground pipes, conduits and metal structures. Part of this is the result of electrolytic action, while part is caused by conditions of the soil. The bureau has mapped out an extensive program to study this subject, and, if possible, to suggest means for preventing the waste. Pieces of pipe have been buried in different sections of the country, and the effect of the soil in these localities on the metal will be studied.

Most appliances used for heating by gas are operated at very low efficiency, with a consequent waste of gas and also with a very bad effect on persons working in the same room, because imperfect combustion means generation of carbon monoxide, which is extremely poisonous. The bureau has studied the subject of improving both natural and artificial gas burners very thoroughly and has already issued recommendations which will greatly reduce gas consumption and improve the health of the users.

In the field of building construction, more material than is necessary is often used for a wall, column or floor slab, because information concerning the stresses which such structures or members can safely bear, their ability to resist fire, etc., is inaccurate or incomplete. In order more definitely to formulate safe and economical standards in this field, the bureau is investigating the suitability of re-rolled steel as a reinforcement for concrete, the strength of walls and floors, the resistance of buildings to fire and the constitution of cement and concrete.

If, through these investigations and many others similar to them which might be mentioned, the bureau can assist in preventing even a small portion of the avoidable waste in industry, the saving to the citizens of this country thus brought about would more

(Continued on page 1239)

Fixed Nitrogen Research Laboratory Reports Work of Past Year on Fixation Processes and Nitrogen Compounds

IN HIS annual report, F. G. Cottrell, the director of the Fixed Nitrogen Research Laboratory, reviews the work of the laboratory and summarizes the principal investigations which have been conducted in the matter of the fixation of atmospheric nitrogen. Since this is the first year the laboratory has been under the Department of Agriculture, the report is prefaced by a brief statement as to the establishment and previous work of the laboratory.

Seventeen technical reports on the work of the laboratory were prepared during the past year. In the present state of development of fixation processes in this country, fixed nitrogen cannot be produced for fertilizer purposes in competition with Chilean nitrate and with ammonia obtained as a byproduct in the coking of coal, except under unusually favorable circumstances. There is every reason to believe, however, that the cost of fixation can be materially reduced through further study and development. During the past year the laboratory has studied the cyanamide, synthetic ammonia, arc and alkali cyanide processes with that object in view.

Ammonia Synthesis

The direct synthetic ammonia process has received considerable attention during the past year. The main features of this process which require further development and on which the laboratory has been engaged during the past year are: The catalyst problem, involving the large-scale production of an active catalyst, the further development of the present catalyst, and the search for new and improved catalysts; the production and purification of the hydrogen-nitrogen mixture; the development of apparatus which will stand the unusually high pressures and temperatures used; and the removal of the synthesized ammonia from the unconverted gas.

Cyanamide Process

The laboratory has made a rather critical study of the present form of the cyanamide process, from which it appears that improvements leading to a drastic reduction in the cost of operation are rather improbable. The process requires a relatively large amount of electric power for the manufacture of carbide, and hence cheap power is necessary to its profitable operation. Important data on the formation and decomposition of cyanamide have already been obtained, but further study is required to complete the investigation.

Next in importance to the fixation of nitrogen is the transformation of the different nitrogen-containing substances in order to make them more useful in agriculture, in explosives and in the arts. During the past year the laboratory has conducted a number of investigations in this connection.

Urea, for example, is one of the most attractive nitrogen-containing materials from the fertilizer standpoint, but at the present time its cost for such use is prohibitive. The laboratory has developed on a semi-technical scale a process for the production of urea from ammonia and carbon dioxide which seems to possess possibilities of ultimately yielding this material at fertilizer prices.

The laboratory is making a rather extensive study of the chemistry of cyanamide and its derivatives to open up this new and cheap source of numerous, useful compounds. During the past year methods have been developed for the production of free cyanamide (H_2CN_2) in quantity, for the production of urea from cyanamide on a semi-technical scale, and for the preparation of guanidine salts. Cyanamide derivatives which appear to have value as ingredients in explosives have also been studied and the results of the investigations communicated to the ammunition division, ordnance office, War Department. In addition, a theoretical investigation on the chemistry of cyanamide was made for the purpose of clarifying the chemistry of this large group of compounds. This investigation is being continued.

Numbering of Steels Referred to Engineering Standards Committee

After extended discussion of the problem involved in the numbering of steels, the conference called by the American Engineering Standards Committee, at the request of the Bureau of Standards, decided the matter could be handled better by a sectional committee of the American Engineering Standards Committee. For that reason no plan or program was adopted so that the sectional committee could consider the matter without limitations as to whether the classification be based on chemical analysis, heat treatment or physical tests.

It was the sense of the conference that there should be a uniform numbering system for forging, casting, structural, tool and other steels, including structural plates.

France and Switzerland are the only two countries which have given serious consideration to this problem, it was brought out, but it is believed something can be learned from the experience in those countries. It was the general opinion that a code of numbering would be useful only when based on definite specifications. It was suggested that the American Society for Testing Materials and the Society of Automotive Engineers be named as sponsors for the consideration of the problem.

Proposes Government Operation of Muscle Shoals

Representative Dickinson Introduces Bill to Form Federal Operating Company for Production of Explosives and Fertilizer—Farm Bloc Withdraws Support of Ford

A GOVERNMENT - CONTROLLED corporation to produce nitrate for war purposes and cheap fertilizer for farmers has been proposed as a solution of the Muscle Shoals problem by Representative Dickinson, Republican, of Iowa, a leader of the "farm bloc," who introduced a bill to put his plan into effect.

In a statement introducing the bill, Mr. Dickinson expressed the feeling that the general criticism to which the Ford offer has been subjected is so strong as to endanger the future disposition of the plant and that the importance of an early conclusion in this is a matter so grave that he is led to the conclusion that some plan of federal operation is the only solution that will insure early completion and operation for the production of farm fertilizer at the lowest possible cost.

Provisions of Bill

The bill provides that a government-controlled corporation, to be known as the Federal Chemical Corporation, to consist of five members, three to be appointed by the President, the two others to consist of the Secretary of War and the Secretary of Agriculture, shall be given full power to complete and operate the plant for the manufacture of fertilizer at the lowest possible cost, for distribution among the farmers, with further power to sell the excess water power under conditions, limitations and safeguards of the national water-power act.

The proposed bill will conserve the $100,000,000 of government funds invested in a nitrate plant at Muscle Shoals for future war-time needs, and during peace provide for the operation of the plant for the manufacturing of fertilizer.

Fertilizer is to be manufactured and sold without profit except a 4½ per cent interest charge on any additional funds necessary to complete and equip the plant for such purpose. No item of war expenditure to date has been converted to the needs of agriculture. The decline in soil fertility endangers our food production.

The placing of the Muscle Shoals plant in the hands of any individual tends to monopolize such production, besides putting in his hands immense water power of great value for manufacturing purposes.

Would Complete Dams

Dams on the Tennessee River contemplated in 1918 would be completed under Mr. Dickinson's bill, and surveys would be made for storage reservoirs. Wherever private interests benefit from the establishment of these reservoirs the bill stipulates they shall bear a proportionate share of their cost.

Another section of the measure provides that, subject to the approval of the President, the corporation be authorized to negotiate with the Alabama Power Co. to settle "the difficulties existing between the Government of the United States and the said power company by virtue of the joint ownership of the power plant at Gorgas, Ala., and it is authorized to sell the interest of the Government of the United States in said plant to the said Alabama Power Co."

Disposition of Plants

Nitrate Plant No. 1 under the plan would be remodeled to manufacture explosives and fertilizer, and Plant No. 2 would be used altogether for the production of fertilizer to be sold to consumers directly or through agencies in various parts of the country. The corporation also would be authorized to fix prices for fertilizer charged by private manufacturers who buy raw materials from the Muscle Shoals plant.

Discussion of Ford Offer Revived

The breach between Senate farm bloc members over the Muscle Shoals project was reopened last week in an hour's tilt between Senator Heflin, Democrat, of Alabama, who again urged acceptance of Henry Ford's development offer, and Chairman Norris of the Agriculture Committee, who opposed the Ford proposal.

Senator Heflin asserted, and Senator Norris denied, that Mr. Ford proposed to cut fertilizer prices in half if his offer for the power plant should be accepted. Senator Heflin scored the government development project in the bill of Representative Dickinson, and declared that the Norris government operation bill would block developments of power or fertilizer.

See Surrender of Farm Bloc

Representative Kearns of Ohio, member of the House Military Affairs Committee, commenting on the Dickinson bill, said:

"I note that Representative Dickinson, a member of the farm bloc of the House, has introduced a bill providing for government ownership and operation of the nitrate plants and part of the water-power projects at Muscle Shoals, Ala. This, the newspapers state, means that the farm bloc has abandoned its support of Henry Ford. I am glad the truth in regard to the so-called Ford offer for Muscle Shoals is finding the light.

"The advocates of the Ford offer urged the acceptance of it to save the government from government operation of the nitrate plants. The advocates of government operation of the nitrate plants urged scheme to save the government from endowing Henry Ford with a government subsidy.

"Neither course is necessary. Congress has already provided sufficient funds to carry on the work of completing the Wilson Dam at Muscle Shoals up to September, 1923. Doubtless a further appropriation will be made by this Congress, available within the next fiscal year. That is all that need to be done about Muscle Shoals.

Should Wait for Water Power

"Very important experiments on a commercial scale in the manufacture of fertilizer materials are now going on under scientific leadership here and abroad. It is practically a certainty that long before the Wilson Dam can be completed scientific knowledge in relation to the production of atmospheric nitrogen will be tremendously advanced. This is no time to make plans for nitrogen fixation which could not in any case be carried out for 3 or 4 years. Any plans made now would quite likely be utterly obsolete by the time the power becomes available through the completion of the dam.

Ford Proposal Unfair

"The Ford propagandists have been diligent in getting to the public statements relative to the making of fertilizer at Muscle Shoals, but in none of these statements that I have read or heard have they told the farmers the truth about the Ford offer. Mr. Ford's proposition does not guarantee the manufacture of fertilizers, but he does have in mind, if he should get these properties and a hundred-year lease of the water power at Muscle Shoals, the carrying on of a gigantic manufacturing plant for his own selfish purposes. I cannot bring myself to believe that the government ought to finance his scheme for him. I do not believe he ought to be given something that no other man or set of men can be given in the United States. My only object in opposing the Ford offer is to call the attention of the public to the true facts, and whenever the country knows the truth in connection with the Ford offer I do not believe there will be one fair-minded and unprejudiced man in the entire United States who will say the Ford offer ought to be accepted."

Chemical Engineers Oppose Licensing Measures

At the Richmond meeting of the American Institute of Chemical Engineers held Dec. 6 to 9, the following resolutions were passed:

Resolved, That the American Institute of Chemical Engineers reiterates its opposition to the licensing of chemical engineers and to the activities of those agencies that are fostering this movement. And be it further

Resolved, That the American Institute of Chemical Engineers encourage and lend its moral support to legitimate efforts to defeat or repeal such legislation as far as chemical engineers are concerned.

G. E. Co. Establishes Prizes for Electrical Advances

Charles A. Coffin Foundation Will Furnish Rewards for Service and Inventions in Electrical Field

Prizes to encourage and reward service in the electric field will be given annually, it is announced by the General Electric Co., from the income of a $400,000 fund in honor of Charles A. Coffin, who founded the company.

The foundation will be controlled and administered by a foundation committee appointed by the board. This committee, within the limits of the purposes for which the foundation is created, will have power to change the conditions applicable to the distribution of the fund and the amounts for each particular purpose.

The income of the foundation will be distributed in four ways—to employees of the General Electric Co., public utility companies, electric railway companies and American technical schools.

To Reward Employees

Eleven thousand dollars in prizes will reward the most signal contributions by employees of the General Electric Co. toward the increase of its efficiency or progress in the electrical art. Particularly, the prizes are to further encourage suggestions from workmen. With each prize the company will give a certificate of award. Foremen's prizes are to be awarded for the best department, taking into account its appearance, efficiency of operation and conditions which add to the better conduct of the work and the welfare of the employees.

Recognition for Public Utilities

A gold medal, to be known as the "Charles A. Coffin Medal," will be awarded annually to the public utility operating company within the United States which, during the year, has made the greatest contribution toward increasing the advantages of the use of electric light and power for the convenience and well-being of the public and the benefit of the industry. The company receiving the medal will also receive $1,000 for its employees' benefit or similar fund.

A gold medal, to be known as the "Charles A. Coffin Medal," will be awarded annually to the electric railway company within the United States which, during the year, has made the greatest contribution toward increasing the advantages of electric transportation for the convenience and well-being of the public and the benefit of the industry. The company receiving the medal will also receive $1,000 for its employees' benefit or similar fund.

To Aid Technical Students

Five thousand dollars is to be awarded annually for fellowships to graduates of American colleges and technical schools who, by the character of their work and on the recommendation of the faculty of the institution where they are studying, could with advantage continue their research work either here or abroad; or some portion or all of the fund may be used to further the research work at any of the colleges or technical schools in the United States. The fields in which these fellowships and funds for research works are to be awarded are electricity, physics and physical chemistry. A committee appointed by the foundation committee will award such fellowships and funds for research work, with the advice and co-operation of a committee of three, one to be appointed by each of the following: National Academy of Sciences, American Institute of Electrical Engineers, Society for the Promotion of Engineering Education.

This committee is to be known as the Charles A. Coffin fellowship and research fund committee and the fellowships are to be known as the Charles A. Coffin fellowships. The expenses of the committee are to be paid out of the income of the foundation.

Charles A. Coffin

On May 16, 1922, Charles A. Coffin, in his seventy-eighth year, retired from the active leadership of the General Electric Co. Mr. Coffin has been identified with the development of the electrical industry since 1882. He was the founder and creator of the General Electric Co., of which hs has been the inspiration and leader for 30 years.

Dr. Rosenhain's Lecture Tour in America

Dr. Walter Rosenhain, head of the metallurgical department of the National Physical Laboratory (that British institution corresponding somewhat to the American Bureau of Standards), and widely known for his erudition, will tour the Eastern states during February and March, 1923, lecturing before various universities and educational organizations. His itinerary, as at present arranged, follows:

Lehigh University, Bethlehem, Pa., Feb. 14 to 16; Franklin Institute, Philadelphia, Feb. 15; American Institute of Mining Engineers, annual meeting, New York, Feb. 19 to 23, where he will speak at the banquet, Feb. 21, and deliver the second Institute of Metals lecture on Feb. 20 or 21; Columbia University, New York City, Feb. 23; Yale University, New Haven, Conn., Feb. 26 to 28; Waterbury, Conn., March 1 and 2; Providence, R. I., March 3; Massachusetts Institute of Technology, Cambridge, Mass., March 5, 6 and 7; Schenectady, N. Y., March 8 and 9; Rome or Corning, N. Y., March 10; Case School of Applied Science, Cleveland, March 12 and 13; Detroit, Mich., and Ann Arbor, Mich., March 14 to 19; University of Illinois, Urbana, Ill., March 20 to 22; Chicago, Ill., March 23 and 24; Toledo, Ohio, March 26; Huntington, W. Va. (International Nickel Co.), March 27; Charleston, W. Va., March 28; Pittsburgh, Pa., March 29 and 30; Washington, D. C., March 31 to April 4 or 5; New Haven, Conn., dedication meeting of the American Chemical Society.

The subjects of his lectures are as follows: Hardness and Hardening; The Structure and Constitution of Alloys; Strain and Fracture in Metals; Aluminum Alloys; Metallurgical Research at the National Physical Laboratory.

The subject of the second annual lecture before the Institute of Metals Division of the American Institute of Mining and Metallurgical Engineering is to be entitled "Solid Solutions," with which he expects to deal on theoretical and fundamental lines.

Before the Franklin Institute, he will deliver the second lecture above, "The Structure and Constitution of Alloys," under which title he expects to deal with the constitutional or equilibrium diagrams of alloy systems, their experimental determination and their full interpretation.

Which of the other lectures will be given at the other dates cannot be stated. Engineers who wish to attend any of these lectures given near their home will do well to communicate with W. M. Corse, National Research Council, Washington, D. C.

Materials of Construction Topic Planned for A.C.S. Meeting

A symposium on "Materials of Chemical Equipment Construction" is being planned for the spring meeting of the American Chemical Society by the Industrial Division. The literature upon this subject is so widely scattered that in many cases much time must be spent in duplicating work which has already been done. The symposium will tend to bring together such matter for which chemists are constantly in search. Philip A. Singer, of the Singer-Perlstein Co., Chicago, Ill., will act as chairman of this symposium.

The subject matter of the symposium will cover woods, metals, vitreous materials, coatings, rubber, fabrics, etc. All of these headings will deal with the resisting properties to acids and alkalis, their resistance to temperature, oxidation characteristics, cost, chemical composition, etc.

Prospects Bright for Helium Development

After having listened to extended testimony with regard to the helium situation, the Committee on Public Lands of the House of Representatives on Dec. 14 closed its hearing on the bill providing a comprehensive helium program. It is very apparent that the committee is favorably inclined toward the measure. In addition to the testimony of R. B. Moore, chief chemist of the Bureau of Mines, and of the helium specialists in the army and navy, a representative of the American Investment Corporation, which is interested in the commercial airship, testified. Each of the witnesses sought to prove that helium is essential to the development of lighter-than-air craft, either for military or commercial uses.

Meeting of Chicago Section, American Ceramic Society

Proposed Ceramic Course at New Crane Junior College and Technical Man's Status in Production Discussed

Nearly seventy members of the Chicago Section, American Ceramic Society, attended the annual meeting which opened with a luncheon at the Morrison Hotel, Saturday, Dec. 2. It is not possible to attribute the large attendance entirely to the fact that a handsome pottery lamp base was to become the property of some lucky member, for the enthusiasm continued unabated even after C. A. Underwood's name had been drawn from the hat. The proposed course in ceramics at the new Crane Junior College is a subject which is of direct interest to every ceramic man and the technical program presented many interesting and instructive features.

Officers for the ensuing year were elected as follows: Chairman, B. T. Sweely; vice-chairman, W. W. Wilkins; secretary-treasurer, H. E. Davis; councilor, C. W. Parmelee.

Proposed Ceramic Course

Facilities for technical education in ceramics are increasing every year, but so far there has been little attempt in this country to provide training for craftsmen in the industry. It is felt that a course in ceramics in some of the technical secondary schools would prove of great value in arousing interest in the ceramic industries. Some of the young men might wish to pursue their studies further along this line at the universities, while others might seek employment with ceramic plants, where their training would be of benefit not only to themselves but to their employers as well.

A. Meyer, assistant principal of the new Crane Junior College in Chicago, has made a thorough study of the whole situation and is most enthusiastic over the possibility of establishing a course in ceramics in this school. In his address he pointed out how such a course would fit in very nicely with the curriculum and stated his belief that the appropriation could be obtained without difficulty if the matter were presented to the proper authorities. After a number of members had brought out the value of such training from different points of view, it was resolved to appoint a committee to draw up appropriate resolutions urging the establishment of this course, and to bring the matter to the attention of the proper officials of the Chicago Board of Education. The committee consists of H. T. Bellamy, chairman; G. G. Lawson and H. C. Beasley.

The paper on the design and construction of a new enamel smelter which was presented by H. E. Davis, of the Northwestern Terra Cotta Co., is of considerable interest and is abstracted on page 1211 of this issue.

Defects to which enameled steel ware is subject were discussed by B. T. Sweely, of the Cribben & Sexton Co., manufacturer of stoves and ranges. The importance of proper pickling conditions was stressed and recommendations were made for the proper application of the ground coat. Mr. Sweely stated that flat ware should never be burned to exceed 1,600 to 1,625 deg. F. if the steel is to be kept straight. With hollow ware, temperatures of 1,700, 1,750, 1,800 or even up to 1,850 deg. F. may be used. He attributed fish scaling to a condition where the coefficient of expansion of the enamel is lower than that of the steel. While this is by no means the only factor, it is a very important one and this trouble can be largely overcome by having the expansivity of the enamel equal to or greater than that of the steel.

Incidents from actual experiences were used most effectively by E. O. Herman, of A. D. Little, Inc., to show how the technical man may be of greater value to the production department.

Co-operation Between Plant and Laboratory

In general, the production man is chiefly interested in more pieces and lower costs, while the laboratory technical man is concerned with quality. Unfortunately in many cases the two types of men cannot understand each other because they really speak different languages, and often little attempt is made to view problems from the standpoint of the other man. Co-operation in such cases is obviously difficult, if not impossible.

There is an opportunity for a technical man with the proper training to act as interpreter between the research or laboratory man and the production man. Endless tact and patience are required for such work, but it results in proper recognition of the value of the technical department by the production and sales departments and thus reacts for the good of the whole organization. Necessary steps in obtaining recognition were summarized as contact, conference, confidence and co-operation.

Mr. Herman also pointed out the importance of going out after problems so that the technical control will function as a preventive and not only as a curative agent. The accounting department and salesmen's meetings offer fertile fields for discovering worthwhile problems. In order to accomplish these results, however, it will be necessary for the technical man to study many subjects, particularly those relating to the non-technical phases of business.

New Paint Plant of Pittsburgh Plate Glass Co. Nearly Complete

The Pittsburgh Plate Glass Co. is completing in Milwaukee, Wis., the first unit of what will be the largest single paint and varnish plant in the United States, Ludington Patton, vice-president of the company, asserts. All the scattered paint and varnish laboratories of the company will be consolidated at Milwaukee.

Determination of Dye Strength Standards Delayed by Lack of Funds

Work of the interdepartment committee of chemists appointed to determine for the Treasury Department the commercial standards of strength of dyes in use prior to July 1, 1914, which is to be the basis for the assessment of import duties under the new tariff act, has been delayed owing to the difficulty of obtaining some of the old samples and because of the slowness of Congress in authorizing an appropriation for extension of the Customs Division's laboratory at New York.

This work, however, is expected to be finished early in the new year, at least so far as affects the colors which are imported in large quantities. Dyes which were imported in single strength prior to July 1, 1914, but now are imported in double concentrations will be assessed for duty at twice the rates mentioned in the tariff act. The committee in charge of determining standards of strength is composed of Dr. G. W. Knight, chemist in charge of the New York customs laboratory; Peter Feiberger, specialist in dyes attached to that laboratory for special assistance in administering the new tariff on coal-tar products; W. A. Watson, color specialist of the chemical division of the Tariff Commission, and G. Appell, of the chemistry division of the Bureau of Standards.

The Customs Division is working on permanent regulations for the administration of the coal-tar rates. One of the important clauses which has received tentative approval for these regulations is that whenever a color which has been imported as non-competitive, thus paying duty on United States selling price, is found to be competitive with a domestic product, which would cause the higher American value to be assessed under the law, 30 days' notice of this fact shall be given importers in order that imports in transit may be entered before the higher rate becomes effective. This tentative decision has been reached on the ground that such a change would be one of classification and not of appraisement, and changes of classification affecting rates for many years have been given 30 days' notice by the Treasury Department.

To Protest Freight Rate on Empty Carboys

Empty carboys should take a lower freight rate than loaded carboys, in the opinion of the traffic committee of the Manufacturing Chemists' Association, but before filing a formal complaint to secure such an adjustment in rates, the committee will await a report from the carboy test committee, which now is conducting experiments in loading and packing. At present returned empty carboys take a higher classification than do the loaded carboys. The committee voted to recommend a petition for the reduction of the carload minimum of 24,000 lb. on empty returned carboys, to 17,000.

Photography Holds Floor at Rumford Hall

Four Papers on Various Phases of the Art and Its Application Presented at Joint Meeting

Friday, Dec. 15, was photographic night at the Chemists' Club auditorium, when the Society of Chemical Industry held a joint meeting with the Technical Photographic and Microscopical Society and heard four excellent papers on photochemistry, color photography, motion pictures and the application of microscopy and photomicrography to the paint and rubber industries.

Dr. A. B. Hitchins, of the Ansco Co., was the first speaker and made some informal remarks on the importance of motion pictures to industry. He emphasized the value of the cinematograph in motion study, in sales promotion, general publicity and educational work. One of the most interesting points brought out by the speaker was his mention of a motion picture history which is now being compiled.

Photographic Emulsions

"Photochemistry and Photosensitive Material" was the subject of a paper by F. F. Renwick, of E. I. du Pont de Nemours & Co. He described briefly the process of manufacturing photographic emulsion by adding a solution of silver nitrate to a solution of potassium bromide, iodide and gelatine. After mixing, the emulsion is ripened—that is, maintained at a definite temperature for a definite time, during which period the grains of silver bromide grow and their sensitiveness increases. The emulsion is then allowed to solidify and is pressed through a die by a hydraulic ram, forming shreds which are washed in cold water, drained and then remelted. A small amount of chrome alum is added to act as a hardener and the emulsion is coated on the film.

This is the process in a few words but, simple as it sounds, it is one of the most complicated and least understood manufacturing processes in industrial chemistry. A slight variation in the temperature or time of digestion, size of grains, quality of gelatine or other raw material, age of emulsion or the extent of the washing to remove soluble bromides, all exert a tremendous influence over the quality and properties of the finished product. The speaker emphasized the importance of obtaining exactly the right grade of gelatine and stated that it is impossible to obtain American-made gelatine which is as satisfactory as the imported material. Mr. Renwick showed some slides illustrating the apparatus used in the large-scale manufacture of emulsions and concluded his talk with some illustrations showing the value of dyes as sensitizers.

Color Measurement

Dr. Herbert Ives presented a talk on color measurements, treating it from two standpoints—the artistic and the physical. Considered from the artistic standpoint, it is a hopeless task to attempt to duplicate in photography the thousands of colors that exist in nature. Dr. Ives explained briefly how, by means of three dimension co-ordinate charts, any shade may be resolved into its constituent primary colors and synthesized.

The value of the microscope in industrial problems was brought out in a paper by Henry Green, of the New Jersey Zinc Co., who described the newly developed product known as 1-A zinc oxide, which is used as a pigment filler in rubber and paint. This grade of zinc oxide is so finely subdivided that it is really in a class by itself, only gas black being of a degree of subdivision to compare with it. Mr. Green showed a number of slides which illustrated very graphically the remarkable degree of subdivision which has been obtained in this pigment, and showed by tests on automobile tires how it improves the quality of the rubber in which it is used. He also discussed the relation of pigment size to the hiding power and plasticity of paints.

Badische Plants Closed by Strike

All the works of the Badische Anilin und Soda Fabrik at Ludwigshafen and at Oppau are closed as a result of a strike which throws about 22,000 men out of work. It is reported that a number of workmen in other industries in Ludwigshafen have begun a sympathetic strike, but their efforts to make it general have so far failed. Mannheim, up to the present, is free from strikes. Statements that the movement is Communistic are made in pan-German circles, but should be received with caution. The strike in the aniline works originated owing to the refusal of the management to reinstate three dismissed members of the workmen's council.

Arsenic Situation Clarified

(Continued from page 1234)

cents and sell calcium arsenate in the South for 14 cents, but with 10-cent arsenic and 14-cent calcium arsenate the manufacturer should be able to make a legitimate profit.

Producers to Increase Output

Hamilton M. Brush gave some high spots in the history of the arsenic industry as viewed by the largest single producer. From 1910 to 1913 arsenic was purely a byproduct and was sold or given away in order to get it out of the plant. The price then was about 3 cents per pound. It is not until the price gets up to 6 or 7 cents that any arsenic can be recovered at a profit and it is only after the price is up to 10 cents that the smelter can begin to make money. The present production of the American Smelting & Refining Co. is about three times what it was in 1911 and twice what it was last year. Sales in 1922, which were six times those of last year, averaged 7½ cents a pound. However, the sales record, both as to volume and price, showed tremendous fluctuation from month to month, making it practically impossible for the producer to predict either market or price. He expressed the belief that if it were possible to stabilize the arsenic market at a price somewhere between 8 and 10 cents per pound, it would be possible for the producing interests in this country to take care of any possible demand from the insecticide manufacturers. Mr. Robertson, of the United States Smelting & Refining Co., confirmed Mr. Brush's statement as far as his own company was concerned. Their production is now sold up to June, 1923, and average sales have been at 8.30 cents. A representative of the American Metals Co. stated that its production in Mexico at one time had varied between 200 and 500 tons per month.

For the purpose of preparing a summary of the meeting to be given out to the press and also to act as a co-operative agency to work with various governmental departments, the following standing committee was appointed by the chairman: B. R. Coad, of the Department of Agriculture; George F. Loughlin, of the U. S. Geological Survey; H. M. Brush, of the American Smelting & Refining Co.; F. Y. Robertson, of the U. S. Smelting & Refining Co.; R. N. Chipman, of the Chipman Chemical Engineering Co.; Frank Hemingway, of the Sherwin-Williams Co.; O. A. Hasse, of the Glidden Co., and W. O. Tuck of the Corona Chemical Co., representing the Pittsburgh Plate Glass Co.

Bureau of Standards Trying to Eliminate Waste

(Continued from pgae 1235)

than pay the cost of many research institutions as large as the Bureau of Standards for a number of years.

New Divisions

Two new divisions, the work of which is of great interest to the public, have been added during the year. The first is the Division of Building and Housing, while the second is that of Simplified Practice.

The Division of Simplified Practice is working in close co-operation with American industries to eliminate useless sizes of the commonly used industrial products and is directing the attention of manufacturers to the advantages of concentrating on the sizes and types in greatest demand.

The variety of the bureau's work is indicated by the fact that its report covers, besides those activities just mentioned, investigations in the fields of weights and measures, electricity, heat and thermometry, optics, chemistry, engineering physics, structural, engineering and miscellaneous materials, metallurgy and ceramics.

Association for Advancement of Science Plans Meeting

The Boston meeting of the American Association for the Advancement of Science, to be held Dec. 26 to 30, promises to be of considerable interest to chemists. There will be an extensive symposium on the progress of chemistry in which some noted chemists will take part. In addition, there will be a symposium on photochemistry and photochemical reactions. The American Physical Society has invited the visiting chemists to attend a symposium upon ionization potentials and atomic radiation. The meetings will begin Wednesday at 9 a.m. in the Massachusets Institute of Technology, and will continue until Friday evening, or possibly until Saturday. The titles of the papers to be presented in the symposia are given below. In addition to these papers there will be a considerable number of reports upon research work in progress in different institutions.

PHOTOSYNTHESIS AND PHOTOCHEMISTRY

Thursday afternoon will be devoted to the symposium on photochemistry and photochemical reactions. Among the speakers scheduled are S. E. Sheppard, of the Eastman Kodak Co., and H. A. Spoehr, of the Desert Laboratory.

PROGRESS OF CHEMISTRY

The symposium on the progress of chemistry will extend over all three days. The program follows:

"Compressibilities and the Size of Atoms," by T. W. Richards, Harvard University.

"Proteins and the Theory of Colloidal Behavior," by Jacques Loeb, Rockefeller Institute.

"X-Rays," by William Duane, Harvard University.

"X-Rays and Crystal Structure," by George L. Clark, Harvard University.

"The Chemistry of Volcanic Action," by A. L. Day, Geophysical Laboratory.

"Chemistry at the Fixed Nitrogen Laboratory," by F. G. Cottrell, director of the laboratory.

"The Chemistry of the Photographic Process," by C. E. K. Mees, Eastman Kodak Co.

"The Properties of Elements and of Groups of Elements in an Electronegative Condition, With Reference to the Constitution of the Metallic Compounds," by C. A. Kraus, Clark University.

"Changes in Volume During the Solution of Solids," by Gregory P. Baxter, Harvard University.

"International Critical Tables," by E. W. Washburn, National Research Council.

"The Present Status of the Theory of Complete Ionization," by D. A. MacInnes, Research Laboratory of Physical Chemistry, Massachusetts Institute of Technology.

"The Present Status of the Theory of Incomplete Ionization," by James Kendall, Columbia University.

"Ionization Potentials and Chemical Action," by W. A. Noyes, Jr., University of Chicago.

"The Separation of Isotopes," by R. S. Mulliken, University of Chicago.

"The Structure of Atoms and the General System of Isotopes," by William D. Harkins, University of Chicago.

The members of Section C are invited to attend a symposium on "Ionization Potentials and Atomic Radiation," to be held by Section B. The speakers are Paul D. Foote, K. T. Compton and Henry Norris Russell.

On Friday evening the section will be entertained at a smoker to be given by the Northeastern Section of the American Chemical Society.

German Potash Prices Jump 145 Per Cent in Month

According to cable advices received by the Department of Commerce, German potash prices effective Dec. 1 were approximately 145 per cent higher than those of Nov. 1.

November potash deliveries were stimulated by impending increases in price and freight rates, which increases became effective Dec. 1. Export sales also increased, and orders were received from countries which had not been previously purchasing.

A decreased demand for coal-tar dyes is reported for the month of November.

Personal

Prof. DUFF A. ABRAMS, head of the Structural Materials Research Laboratory, Lewis Institute, Chicago, Ill., gave an interesting address on the subject of "Some of the Subtle Properties of Concrete," at a meeting of the Engineers' Club, Trenton, N. J., Dec. 7.

R. L. AGASSIZ, president of the Calumet & Hecla Mining Co., New York, and Calumet, Mich., has been elected president of the Copper and Brass Research Association.

C. H. BRANDES is returning to New York the latter part of December after a 4 months' business trip in Europe.

GELASIO CAETANI, recently appointed Ambassador from Italy to the United States, expects to arrive about Dec. 20. He has accepted the proposal of the American Institute of Mining and Metallurgical Engineers to give a dinner in his honor at a convenient date after his arrival.

M. G. DONK, for the last 2 years a chemist connected with Edgewood Arsenal and previous to that time connected with several large private chemical works, has been added to the staff of the chemical division of the Tariff Commission. He will specialize in heavy chemicals. The Tariff Commission also has added to its chemical division Mrs. FLORENCE BURLINGAME, who for several years was a chemical research assistant employed by the War Trade Board. She will have charge of the chemical statistical work of the Tariff Commission.

ELLERY K. FILES, who has been connected with the pyroxylin department of the Duratex Co. of Newark, N. J., has just been appointed manager of that company's rubber department.

Dr. KUNO B. HEBERLEIN will return to New York the latter part of this month after a 2 months' business trip to England.

FRANK W. MCSPARREN, Cornell '14, formerly with the National Aniline & Chemical Co. and the du Pont company, has joined the chemical division of the U. S. Tariff Commission.

Dr. WALTER ROSENHAIN expects to arrive in America early in February and will remain about 2 months. His itinerary and titles of his lectures are given elsewhere in this issue.

THOMAS W. STREETER, vice-president of the American International Corporation, has been elected chairman of the executive committee of the Simms Petroleum Co., 120 Broadway, New York.

W. E. SYMONS, treasurer of the American Welding Society, New York, has resigned.

ALBERT THOMAS, director of the International Bureau of Labor, Geneva, Switzerland, arrived in this country on Dec. 12, and is now touring the principal cities of Canada and of the United States as far west as Chicago. He expects also to visit Havana. On Jan. 19 he will address the New York Conference of Business Paper Editors.

Obituary

Dr. HERBERT CLARK EMERSON, 57 years old, president of Springfield Hospital, war-time fuel administrator of Springfield, former member of the board of health and health physician of the city, an analytical and consulting chemist, died recently at his home.

SPENCER B. NEWBERRY, president of the Sandusky Portland Cement Co., Sandusky, Ohio, died at Cleveland, Nov. 28, at the age of 65.

JAMES REAVEY, for more than 20 years assistant chemist for the San Francisco board of public works, died recently at the Morton Hospital, San Francisco.

PETER D. THROPP, of Trenton, N. J., head of the Trent Rubber Co., the Eureka Flint & Spar Co. and a number of other prominent local companies, died at his residence recently from a stroke of paralysis. He is survived by his wife, a son, a daughter and three brothers.

Prevailing Prices and Market Letters From Principal Industrial Centers

Facts and Figures of the Arsenic Shortage

Government Estimates of Existing Stocks, Production and Manufacturing Requirements—Causes of Present Shortage and Possible New Sources of Supply

AT THE conference of the producers and users of arsenic held in New York, Dec. 13, George F. Loughlin, of the United States Geological Survey, gave a valuable report on the arsenic situation. According to the estimate of V. C. Heikes of the Salt Lake City office of the Survey, the production of refined and crude arsenic during the current year amounted to 10,947 short tons. The sales of crude arsenic amounted to 1,366 tons. All the crude arsenic sold was used in making sodium arsenate, a weed killer, either at the place of manufacture or at places nearer the consumer. The production of refined white arsenic having a purity of 99.5 per cent or more amounted to 9,581 tons, valued at $1,486,000, or 7¾c. a pound. The stocks of domestic arsenic on hand Oct. 1 were reported as 1,230 tons, and the quantity to be made between Oct. 1 and May 1, 1923, was estimated at 3,400 tons.

Supplementing this report, C. R. DeLong, of the Tariff Commission, stated that during the first 9 months of 1922 the imports of all forms of arsenic into the United States amounted to 3,500 tons, of which 2,600 tons was received prior to July 1. The difference, 900 tons, represents the proportion of imports which has not yet entered into consumption. Mr. DeLong also reported that late consular dispatches from Japan indicated there were no stocks on hand and that current production, which is proceeding at a rate of 130 tons per month, is under contract until April, 1923. Nor were either Spain or Mexico in a position to furnish any appreciable quota of arsenic, according to Mr. DeLong's statement.

Domestic Producers

Six Western smelting plants that handle copper and lead ores and are equipped with arsenic refineries made white arsenic, crude and refined, in 1922. The American Smelting & Refining Co., which operates the plants at Globe, Colo., and Tacoma, Wash., reported the largest output. The Anaconda Copper Mining Co. had some difficulty in getting sufficient labor to operate at greater capacity its ore-reduction plants at Anaconda, Mont., but reported the second largest output of refined arsenic and the largest output of unrefined arsenic. At the plant of the United States Smelting, Refining & Mining Co. at Midvale, Utah, the output consisted of refined white arsenic, of which a normal quantity was sold. All the company's crude material was worked up into sodium arsenite solution, many thousands of gallons of which was distributed to railroad companies for killing weeds on rights of way. This weed killer is also made in large quantities by the Chipman Chemical Engineering Co., which purchases crude arsenic for shipment to several of its plants in Eastern and Western states.

Wide Fluctuations in Price

But few commodities in the chemical market have shown as radical price variations as has been the case with

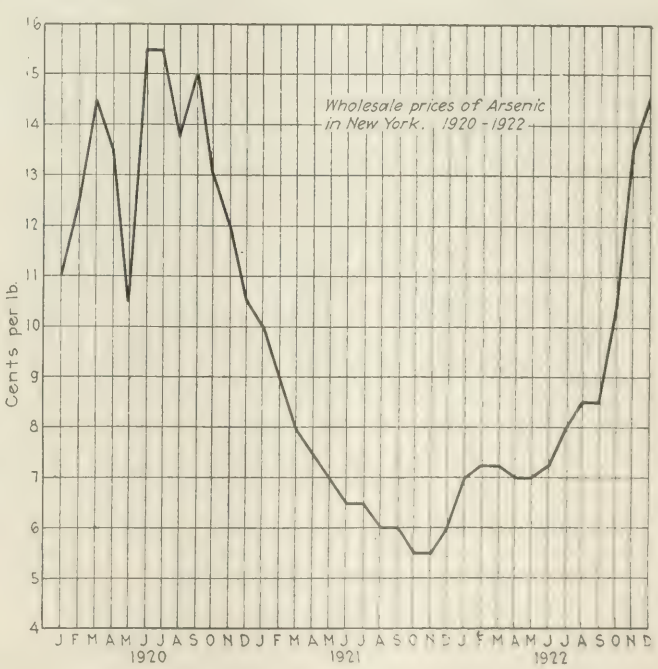
"Chem. & Met." Weighted Index of Chemical Prices

Base 100 for 1913-14

This week	168.73
Last week	161.72
December, 1921	145
December, 1920	245
April, 1918 (high)	286
April, 1921 (low)	140

The marked advance in this week's index resulted largely from the 25 per cent increase in the price of methanol—from $1 to $1.23 per gallon. Other important commodities to show increases were ammonium sulphate, formaldehyde, aniline and linseed oil.

Production and Imports of White Arsenic 1910-1922
Production
Imports
Thousands of Tons
Year
1910 1911 1912 1913 1914 1915 1916 1917 1918 1919 1920 1921 1922



white arsenic. The fluctuations since 1920 are shown in the accompanying chart. During 1922 the range has been from 6c. per pound in January to 15½c. in December. In July the price was 7⅜c. per pound, but in August it suddenly jumped to 8½c., just as the manufacturers of insecticides decided to buy, and it rose rapidly until December. The average price per pound to consumers, however, seems to have been between 7 and 7⅜c., and the maximum price for wholesale lots is understood to have been 8½c. Contracts were said to have been made in October for German and Japanese arsenic, to be delivered in November and December, at 9½@10c. a pound, but dealers predict still higher prices at the beginning of the insecticide season next spring. Lead arsenate, as paste, was quoted at 8@14c. a pound. Red arsenic was quoted at 12 @13c. a pound, and the quotations on calcium arsenate ranged from 11 to 20c. a pound and at the end of November, 10 to 12c. was bid. Elemental arsenic was quoted at 17c. a pound.

Increased Consumption Indicated

In 1922 about five times more lead arsenate was made than all the other arsenical compounds put together, including calcium arsenate, paris green and bordeaux mixture. The reports indicate, however, that during the period from Oct. 1, 1922, to May 1, 1923, the output of calcium arsenate will be larger and that of lead arsenate may be somewhat smaller than heretofore. The makers of plate glass bought their usual quantity of refined arsenic, about 1,000 tons.

The use of arsenic in the United States and abroad in weed-killing compounds has increased during the last year. In the Southern states the cotton boll weevil is being fought with calcium arsenate, of which about 8,000 tons was distributed to the cotton growers in 1922. According to reports received at the Delta laboratory of the United States Department of Agriculture at Tallulah, La., no calcium arsenate remained in the warehouses after September. Dr. B. R. Coad, in charge of that laboratory, reports that the demand for calcium arsenate in 1923 is expected to be twice as great as in 1922. The use of arsenic as a larvacide in mosquito-control work is being extended in the malarial region of the South.

Cause of Shortage of Supply

Though the unusually large demand for arsenical compounds for use as insecticides is doubtless the principal cause of the shortage of arsenic, there are a number of other causes. Among these are the reduction in the quantity of copper ores treated at Anaconda, Mont., and at Tacoma, Wash., the small supply of arsenical dust from the lead smelters in Montana, Utah and Colorado, and the decrease in the imports from Canada, Japan and Mexico. The present demand for arsenic amounts to 12,000 short tons a year, whereas the supply available in 1921 from both domestic production and imports amounted to only 6,455 tons.

Some New Developments

The arsenic plants at smelting works in the United States have an annual producing capacity of 18,300 tons of white arsenic, but their actual output must depend largely on the plans of two smelting companies that contemplate reducing ores and speiss directly for their content of arsenic. At Toulon, near Lovelock, Nev., arsenical ores were reported to have been successfully treated and to have yielded some white arsenic in 1922. The owners of this plant expect that it will produce considerable arsenic in 1923. The American Arsenic Co., at Gold Bar, Wash., was producing red arsenic (realgar) in commercial quantities in 1922, according to a report from the company's engineer. The milling plant on the property has been equipped with a flotation unit and turns out over a ton of powdered realgar a day. The Salt Lake Insecticide Co. is erecting at Salt Lake City a plant for making arsenical compounds directly from ore. The owners estimate that the plant will make a daily output of about 15 tons of calcium arsenate. All the ore to be treated is to be mined at Gold Hill, Utah, from the largest known deposit of basic iron arsenate in the United States.

Wood Chemicals Quoted at New High Levels in the New York Market

A 25 Per Cent Advance on Methanol and a Corresponding Increase on Formaldehyde Feature an Otherwise Colorless Market

PRODUCERS of methanol announced another sharp advance in prices, due, it was stated, to higher producing costs in the face of an increasing demand. The new level represents the highest price of the year and shows a net gain of 62c. per gal. since January, 1922. Along with the advance in alcohol came a corresponding rise in formaldehyde. Prices showed a gain of 1¾c. per lb. and brought the price up to the highest level of the year. The producers report a well sold up condition at the works and all indications point to even a higher market before the turn of the year.

Heavy Chemicals Show Firmness

Trading, in general, was along moderately active lines, probably on account of the approaching holiday season and inventory period. Prices throughout the list, however, showed every sign of firmness, and leading producers were convinced that the new year will bring higher prices on many commodities. White powdered arsenic continued along former strong lines without any evident sign of relief. Spot supplies are very scarce and producers report they are heavily sold ahead through April and May, 1923. Imported material has been quite slow to arrive. Although barium chloride, prussiate, bichromates, permanganate of potash, oxalic acid and nitrite of soda have undergone very little change, prices are fractionally easier in several instances. The alkali market remained quotably unchanged during the interval.

High Spots in the Market

Alcohol—Several large producers announced a new increase in methanol. The 95 per cent product is quoted at $1.23@$1.25 per gal. in barrels, with 97 per cent held around $1.25@$1.27 per gal. Demand is very strong. Denatured and ethyl remain quotably unchanged.

Arsenic—Round lots on spot are exceedingly difficult to locate. Several odd-lot transactions were reported among second hands at 14¾@15c. per lb. Goods afloat were heard around 14¾c. per lb. The two leading producers announced that their production was under contract at prices considerably less than 10c.

Bichromate of Soda—Prices remained unaltered during the week at 7⅞@7½c. per lb. on spot. Contracts for 1923 were quoted around 7½c. per lb. f.o.b. works.

Carbonate of Potash—A slightly easier market prevailed in the calcined 80-85 per cent material. Quotations ranged around 5¾c. per lb. Hydrated 80-85 per cent was somewhat firm at 7c. per pound.

Caustic Potash—Demand has slackened considerably and prices were fractionally lower on spot. Imported 88-92 per cent goods were quoted at $6.25 per 100 lb. Shipments were at the same level.

Caustic Soda—The export market showed signs of easing off, due to the lack of interest. Standard brand goods were held around $3.50@$3.60 per 100 lb. Domestic material continued quite firm at $3.75@$4 per 100 lb. ex-store. Producers quote contracts at $2.50 per 100 lb., basis 48 per cent f.o.b. works, carload lots. Demand for contracts was reported very strong.

Fluoride of Soda—Imported material was quoted down to 9c. per lb. Lack of interest from consumers and competition were directly accountable for the low figure.

Formaldehyde—Large producers announced a new price of 16c. per lb. in carloads and 16½c. per lb. for lesser quantities f.o.b. works. Higher producing costs were responsible for the latter advance. Resale lots were around the market at 15c. per pound.

Permanganate of Potash—An easier tendency featured this market and prices were quoted down to 15c. per lb. on spot. The general range was around 15@16c. per pound.

Sal Ammoniac—Several sales for

white granular were recorded at 6½c. per lb. on spot. Gray material continued quite scarce at 8¼c. per lb. Domestic producers quote the white material at 7¼c. per lb. and the gray at 7⅞c. per lb. f.o.b. works.

Coal-Tar Products

Coal-tar crudes and intermediates continued along moderately active lines and producers were very optimistic regarding the general volume of business transacted. Spot supplies of toluol and benzol were practically inexistent and producers report a heavily sold up market. Manufacturers of cresylic acid reported material sold up as far ahead as March, 1923, and refused to quote for shipment. Phenol, aniline oil, beta naphthol and salicylic acid are showing considerable activity and prices continued very steady.

Prices Advance in Firm Market at St. Louis

Volume of Business Slackening Off, However, as Inventory Season Approaches

St. Louis, Mo., Dec. 14, 1922.

Further advances in prices on a number of the more important chemicals have taken place since our last report, and in general the market has maintained the very firm tone which has prevailed for some time. The activity of the market is about the same as it was 2 weeks ago; however, a slackening off in business would not prove at all surprising, as it is generally expected at this time of the year which is influenced by the approach of the inventory season.

Alkalis Keenly Competitive

Keen competition for business has shown its effect in the alkali market by a decline in prices. Both *caustic soda* and *soda ash* have suffered a decline due to the too earnest desire for business on the part of the producers. *Caustic soda* is now being quoted at $3.90 for solid and $4.25 for flake in 5-drum lots delivered to the consumers' door. Only routine business is being done even at these low prices. *Soda ash* 58 per cent light in bags sells at $2.05 and barrels at $2.30 in 5-bbl. or bag quantities, delivered. *Bicarbonate of soda* is holding firm at $2.25 per 100 lb. and considerable trading is reported. *Sal soda* is in good demand and prices are firm at $1.65 per 100 lb. in barrels.

General and Special Chemicals

The heavy mineral acids are holding their own, and *sulphuric acid* particularly is quite active. Prices remain about the same. The demand for *citric acid* is routine and supplies are more readily procurable. There is still a tremendous scarcity of *white arsenic* in this market. An advance in *carbon tetrachloride* has taken place since our last report and the demand is along routine lines. The *copperas* situation has eased a bit, but prices still remain very firm. There has been no change in the *cream of tartar* and the *tartaric acid* situation since our last report. *Glycerine* contracts are being made now and one large producer is advising the trade that protected contracts for 3 months are the most advantageous to the buyer at this time, since a decline in price is looked for within the next 3 months. Some contracts have been made for 6 months on a flat basis of 18c. with no protection against decline, but most business is for 3 months at 18½c. with protection. A good volume of business is being transacted. *Yellow prussiate of potash* is still in the same tight position it was in a few weeks ago, and very little spot goods are available. *Sulphur* is very quiet at present, with no price change and only routine business being transacted. The *zinc dust* market has improved a great deal during the past 2 weeks. *Zinc sulphate* is maintaining a very active position and prices remain unchanged, the market being very firm.

Oils, Naval Stores and Paint Materials

Castor oil is moving in good volume and prices remain firm at 13½c. in drums for No. 1 grade. *Linseed oil* has not changed in price and is still being quoted at $1 per gal. for single-barrel lots, and 92c. in 5-bbl. lots for the raw oil with the usual differential of 2c. per gal. for boiled over raw. *Turpentine* has suffered a further decline and is now quoted at $1.42 in 5-bbl. lots and $1.48 in single barrels. This is a decline of 10c. per gal. over quotations 2 weeks ago.

Barytes, *blanc fixe* and *whiting* remain firm and in good demand. No price changes have been reported. *Zinc oxide* has been in active demand due to buyers trying to cover requirements against an advance in price which is daily expected. Heavy buying in imported dry earth colors is reported. This, too, is due to an expected price advance that is sure to come with the advance in foreign exchange.

Steady Market for Steel as Output Continues High

December Production Shows Slight Increase Over November and October—Steel Prices Unchanged

Pittsburgh, Dec. 15, 1922.

Steel ingot production in November was at the same rate as in October, about 40,000,000 tons per annum. Thus far this month there seems to have been, on the whole, a slight increase. The current production is fully absorbed. No steel is accumulating at mills and with better car supplies the relatively small tonnages accumulated some time ago are nearly all moved. It is normal for buyers to prefer shipments to be decreased in December on account of the annual inventory, but there is no evidence of any such desire this year. In the case of some commodities a considerable portion of the current deliveries is at prices below those now ruling, and if customers should request postponement of delivery in such cases the rejoinder of the mill would be a suggestion of cancellation.

The finished steel market is quite steady on the whole. Pipe and wire mill products are not merely steady, they are strong, merchant pipe being at 66 per cent basing discount, wire at 2.45c. and nails at $2.70. Tin plate is firm, quantity differentials, from the basis price of $4.75, being smaller than usual. Sheets are fairly steady at 2.50c. for blue annealed, 3.35c. for black and 4.35c. for galvanized. Here and there a mill may be shading slightly, but the market as a whole is quotable at the figures named.

The Steel Corporation's unfilled obligations decreased by 62,045 tons in November, against increases of 210,680 tons in October and 741,502 tons in September. The bare figures do not reflect the trade condition. The showing for September and October was swelled by the heavy business done in rails and track fastenings for shipment to the middle of next year, while November witnessed much heavier shipments, at about 81 per cent of capacity, against 76 per cent for October and 67 per cent for September. Counting out rails and track materials, actual bookings were not much less in November than in either of the two months preceding.

Lower Coke Prices

Connellsville coke has continued to decline. Consumption has increased but little in the past few weeks. Production increased rather sharply until 2 or 3 weeks ago, when it appeared that there was an excess and there were reports that merchant operators intended to curtail. This they do not seem to have done, however. In November producers were making predictions that market prices would advance in December, because snowstorms and bad weather would slow down railroad movement, but the weather has not co-operated. Furnace coke, quotable a week ago at 6.75@$7, a decline of 50c., is now down to the point of being easily obtainable at $6.50 if not at less, while foundry coke is off 50c., at $7@$7.50. There is little demand. Furnaces in general are covered to the end of the year, at considerably higher prices.

There has been a small-sized buying movement in foundry iron in the past 10 days, after an entirely one-sided market had existed for a long time. The decline at last went far enough to interest foundries in a moderate way, and there was partial covering of first quarter requirements by several important interests. Valley foundry iron went at $25 furnace. Both sellers and buyers felt that they were doing backlog business, sellers expecting their later sales to average up and buyers expecting their later purchases to average down. There was little business done in basic. The market is quiet again, with bessemer at $27.50, basic at $25 and foundry at $25 to $26, f.o.b. valley furnaces, freight to Pittsburgh being $1.77.

General Chemicals

Current Wholesale Prices in New York Market

		Carlots F.o.b. N. Y.	Less Carlots F.o.b. N. Y.
Acetic anhydride, 85 per cent	lb.	—	$0.39 – $0.41

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

TARRANT CITY—The National Cast Iron Pipe Co. has tentative plans under way for the erection of an addition to its foundry, work to commence early in the coming year. Arrangements are being perfected for an increase in capital from $500,000 to $1,000,000 for general expansion.

Arkansas

LITTLE ROCK—The Independence Mineral Co., A. G. McGill, president, has plans under way for the development of sperrylite ore properties in Independence County, where a tract of more than 100 acres of land has been secured. It is purposed to install a plant for the production of platinum. T. W. Berr is manager.

California

LOS ANGELES—The Blue Tank Pipe Line & Refinery Co., Long Beach, has acquired a tract of about 15 acres of land at Wilmington, Los Angeles harbor, as a site for the construction of a new refining plant, estimated to cost in excess of $750,000, with machinery. The work will include an oil pipe line, pumping plants and a large tank farm.

STOCKTON—The National Paper Products Co. has awarded a contract to the Davis-Heller-Pearce Co., Delta Bldg., for the erection of an addition to its plant on Church St., near McDougall St., estimated to cost approximately $125,000, with equipment.

TEHACHAPI—The Blue Diamond Materials Co. has arranged for the operation of a local limestone plant for raw material supply.

SACRAMENTO — The Sacramento Pipe Works, Inc., R St., near 7th St., manufacturer of wrought steel pipe, has plans in progress for the construction of a new plant in the vicinity of B and 16th Sts., consisting of a number of buildings, with main structure, 150x230 ft.

SANTA ANA—The Shell Oil Co., 343 Sansome St., San Francisco, is planning for the establishment of a new storage and distributing plant on local site, to consist of a number of buildings, with capacity of 100,000 bbl.

Connecticut

NORWICH—The local mill of the Ironsides Board Corp. has been acquired at public sale by James E. Smith, an official of the Chesapeake Paper Board Co., Woodall and Claggett Sts., Baltimore, Md., for a consideration said to be $195,000. The property includes paper mills, warehouses, mechanical buildings and other structures, and will be remodeled and improved for a branch plant. Additional equipment will be installed to replace certain machinery exempted from the sale.

Delaware

WILMINGTON—J. E. Rhoades & Sons, 11th St. and the Baltimore & Ohio R.R., manufacturers of leather products, have awarded a contract to J. A. Bader & Co., Lackey Bldg., for the erection of a 1-story addition to their tannery, totaling about 5,500 sq.ft. of floor space.

Idaho

LEWISTON—The city water department, E. G. Wagner, superintendent, has preliminary plans under way for the installation of a filtration plant at the municipal waterworks, to cost about $500,000, with equipment.

Illinois

TAYLORVILLE—The Hopper Paper Co. will soon take bids for the erection of a 2-story addition, 80x160 ft., estimated to cost close to $65,000. Billingham & Webb, Press Bldg., Kalamazoo, Mich., are architects.

CHICAGO—The United States Industrial Alcohol Co., 27 William St., New York, N. Y., has commenced improvements to the property at Archer and Western Aves., recently acquired for its local branch works, to include the erection of a number of buildings, estimated to cost about $100,000. Eugene C. Acker & Associates, Chicago, are contractors.

CHICAGO—The Advance Pattern & Foundry Co., 2734 West 36th Place, has superstructure work under way on a new 1- and 2-story foundry addition, to cost approximately $50,000.

Indiana

SHELBYVILLE — The Kennedy Paper Co. has plans under way for the erection of a new local plant, 1-story, 50x130 ft., and will break ground at an early date. Rubush & Hunter, American Central Life Bldg., Indianapolis, are architects.

Kentucky

LOUISVILLE—The J. F. Kurfees Paint Co., Market and Floyd Sts., has acquired property adjoining its plant, 61x200 ft., as a site for the erection of a new 5-story addition, estimated to cost approximately $200,000, with machinery. It is purposed to double the present capacity.

Louisiana

MONROE—The Sterling Gas Products Co., St. Louis, Mo., will commence the immediate erection of new carbon and gasoline plants, with complete refining facilities, estimated to cost in excess of $1,000,000, with machinery. The B. W. Rumberger Engineering Co., Monroe, is engineer and contractor.

Maine

PORTLAND—Frank B. Converse & Co., 27 South St., Boston, Mass., has acquired the tanning plant of the Casco Tanning Co., Forest Ave., Deering Park section, for a consideration said to be $150,000. The new owner plans for extensions and improvements, and will soon resume production at the tannery, operating in conjunction with its other such plants.

Maryland

BALTIMORE—The Holtite Mfg. Co., Warner and Ostend Sts., manufacturer of rubber specialties, has filed plans for the erection of a 1-story and basement addition, 50x155 ft., estimated to cost about $15,000, exclusive of machinery.

Massachusetts

MALDEN — Wadsworth, Howland & Co., 139 Federal St., Boston, Mass., manufacturer of paints, varnishes, etc., has superstructure work in progress on a new 5-story building at its local plant, 53x190 ft., and plans to occupy the structure at an early date.

Michigan

RIVER ROUGE—The Ford Motor Co., Highland Park, Mich., will commence the immediate erection of its proposed new glass plant, with gas producer plant here, with main building 258x360 ft., estimated to cost approximately $1,500,000. The general contract has been awarded to the Everett Winters Co., Book Bldg., Detroit; Albert Kahn, 1000 Marquette Bldg., Detroit, is architect and engineer. The company is also considering the erection of a new cement plant at River Rouge, to cost in excess of $500,000. Albert Kahn is likewise engineer for this structure.

MONROE—The Monroe Paper Co. is considering tentative plans for the rebuilding of the portion of its plant, destroyed by fire, Dec. 3, with loss estimated at $50,000.

DETROIT—The Charles B. Bohn Foundry Co., 733 Hart Avenue, manufacturer of brass, bronze and other metal castings, has plans under way for the erection of a new addition. Christian W. Brandt, 1114 Kresge Bldg., is architect.

Minnesota

HIBBING—The Oliver Iron Mining Co. is perfecting plans for enlargements in its local plants to cost in excess of $130,000, to include the installation of a new crushing and screening plant at the Hull Rust mine, estimated to cost about $98,000, with machinery; extensions and improvements in the crushing and screening plant at the Morris mine; mechanical buildings and shops.

Nevada

EUREKA—The Eureka Smelting & Refining Co. has plans under way for the construction of a new smelting plant, with capacity of about 2,500 tons per day, estimated to cost about $1,200,000. F. L. Torres is president.

New Jersey

PERTH AMBOY — The United Lead Co., Maurer, has work nearing completion on a new 1-story plant addition at its local works, 300x300 ft., and plans to occupy the structure at an early date.

NEWARK—J. H. Armitage & Sons, 240 Thomas St., manufacturers of hatters' glaze, etc., have filed plans for the erection of a new 1-story plant addition. Charles P. Baldwin, 45 Clinton St., is architect.

CHATHAM—The Franken Color Works, Inc., Summit Ave., is planning for the rebuilding of the portion of its plant recently destroyed by fire. An official estimate of loss has not been made.

ELIZABETH — The Bullet Proof & Non-Shatterable Glass Corp., 47-55 South Spring St., manufacturer of special laminated glass, has preliminary plans in progress for enlargements in its plant. A sale of stock is being arranged to carry out the work.

JERSEY CITY—The National Air Cell Co., Henderson St., manufacturer of asbestos products, will commence the immediate rebuilding of the portion of its plant recently destroyed by fire.

PERTH AMBOY — Henry Maurer & Son, Maurer, near Perth Amboy, manufacturers of fire brick and other refractory products, has acquired a tract of property totaling about 10 acres in East Brunswick Township, to be used in connection with expansion in operations.

NEWARK—Fire recently destroyed a portion of the plant of the Fernando C. Mesa Co., Chancellor Ave. and Coit St., Irvington, manufacturer of electrical porcelain products, with loss estimated at about $70,000.

New York

PORT RICHMOND—The American Linseed Co., 297 4th Ave., New York, will soon take bids for the erection of a 2-story addition to its local plant, 60x110 ft., estimated to cost about $30,000.

NEW YORK—The Sterling Products Co., 690 10th Ave., is concluding negotiations for the purchase of the plant and properties of the Charles H. Phillips Chemical Co., 128 Pearl St., for a consideration said to be close to $5,000,000. The Sterling Company plans for the sale of stock issue of about the amount noted to finance the acquisition, including proposed extensions and improvements.

BROOKLYN—Fire, Dec. 6, destroyed a portion of the experimental laboratory of the Brooklyn Rapid Transit Co., 85 Clinton St., at 500 Kent Ave., with loss approximating $10,000, including instruments, chemicals, oils, greases, etc. It will be rebuilt.

DUNKIRK—The Atlas Steel Corp. is planning for the immediate rebuilding of the portion of its plant recently damaged by fire, with loss estimated at about $12,000.

BUFFALO — The Williams Gold Refining Co., 2978 Main St., has completed plans and will soon break ground for the erection of a 3-story addition, 22x50 ft., to be used as a factory and laboratory for refining and assaying. R. H. Williams is head.

BROOKLYN — The Star Cork Co., 175-77 North 9th St., has filed plans for extensions and improvements in its plant.

North Carolina

ROXBORO—The council is having plans prepared for the installation of a filtration plant at the municipal waterworks to cost about $75,000. Bids will be called during the coming spring. The Ludlow Engineering Co., Wadlovia Bank Bldg., Winston-Salem, N. C., is engineer.

Ohio

ZANESVILLE — The Columbia Chemical Division of the Pittsburgh Plate Glass Co., Frick Bldg., has plans near completion for the construction of a new cement and chemical plant at White Cottage, about 7 miles from Zanesville. It will consist of 11 buildings, 1- and 2-story, and is estimated to

cost in excess of $1,500,000, with machinery. The engineering department of the company, address noted, is in charge.

Oregon

PORTLAND—The Cascade China Co., Vancouver Ave., is planning for the erection of a 1-story addition to its pottery.

Pennsylvania

YORK HAVEN—The Conewago Felt & Paper Co., recently organized under Maryland laws with capital of $300,000, has preliminary plans in progress for the erection of a new paper mill, with adjoining plant for the production of dry saturating felt for use in the production of prepared roofing, estimated to cost close to $100,000, including machinery. A site on Conewago Creek, about 1 mile from the city has been selected, and work will be commenced late in February. E. E. Brunner, president of the York Haven State Bank, heads the company.

PHILADELPHIA—The Pennsylvania Brick & Tile Co. will commence the immediate erection of a new plant at the foot of Westmoreland St. and the Delaware River, for the manufacture of cement brick. It will consist of a number of buildings, equipped for an initial output of 150,000 bricks per day, with automatic machinery for conveying and handling. The works will include a chemical department for the production of an "accelerator" to insure rapid drying and production, and will be ready for service early in March. The estimated cost is placed at $100,000, exclusive of realty. Louis F. Drucker is president.

ST. MARY'S—The Elk Graphite Milling Co., recently organized by officials of the Speer Carbon Co., operating a local plant, as a subsidiary organization, has plans in progress for the erection of a new graphite works in the Rettger section. It is proposed to have the structure equipped, ready for service, early in the spring.

JEANNETTE—The American Window Glass Co., Farmers' Bank Bldg., Pittsburgh, plans for the immediate erection of a 1-story addition to its local plant, comprising a second story on existing 1-story structure, to be used primarily as a cutting department and providing for the employment of about 180 additional operatives. It is expected to be ready for occupancy early in the spring.

PHILADELPHIA—H. M. & C. B. Siner, Church and Tacony Sts., manufacturers of brick, will commence the immediate erection of a new addition to their plant at Devereaux and Langdon Sts., including power house.

PHILADELPHIA—The North American Foundries Corp., now being organized, will soon take title to the plant of the Thurlow Steel Co., 4th St., Chester, recently acquired at a receiver's sale for about $75,000. The works will be remodeled for a foundry for the manufacture of steel and semi-steel castings, and is expected to be ready for service early in February. Edwin H. Gackenbach of Gackenbach & Co., Inc., Widener Bldg., investment securities, has purchased the plant for the new company and is interested in the project.

PHILADELPHIA—Fire, Dec. 7, damaged a portion of the plant of the Atlantic Refining Co., Point Breeze, 33rd and Ritner Sts., manufacturer of refined oils. An official estimate of loss has not been made.

LEWISTOWN—The American Refractories Co., Union Arcade, Pittsburgh, has made additional purchases of property in this section, securing a total of 287 acres of land, to be used in connection with its proposed plant.

Tennessee

CHATTANOOGA—The Industrial Department of the local Chamber of Commerce, Henry Longley, secretary, is interested in a project for the establishment of a local graphite plant for the manufacture of lead pencils and other products. It is purposed to select a site at an early date.

Texas

AMARILLO—The United States Zinc Co., 120 Broadway, New York, has commenced surveys for a new smelting plant on tract of about 40 acres of land near the city recently acquired, to be of 5-block type, and estimated to cost about $400,000. Plans for the structure are nearing completion and ground will soon be broken. The smelter will be operated with natural gas.

SAN ANTONIO—The San Antonio Portland Cement Co. has awarded a contract to the Elder Construction Co., San Antonio, for the erection of an addition to its mill at Cementville, near San Antonio.

NACOGDOCHES—The Yuba Oil Co. has tentative plans under consideration for additions in its local refining plant, recently acquired from the Carolina Oil Co., for a consideration in excess of $100,000, including oil lands. The capacity of the refinery will be considerably increased. C. C. Chappell is manager.

Virginia

ROANOKE—The Nortenga Copper & Chemical Corp., 324 MacBain Bldg., recently organized, has acquired property in Cherokee County, N. C., and plans for immediate development. It is purposed to construct a plant at an early date. The company is capitalized at $300,000. E. A. Schubert is president.

NORFOLK—The Scott Terminal Corp. will commence the immediate erection of a new dehydration plant, in connection with storage terminal, 80x450 ft., estimated to cost about $375,000, including machinery.

Washington

FREEPORT—The Concrete Pipe Co., Kelso, is considering plans for the construction of a new plant in this vicinity, where large contracts for reinforced-concrete pipes have been secured.

Capital Increases, Etc.

THE INTERSTATE REFINERIES, INC., Kansas City, Mo., operating oil refineries, has filed notice of increase in capital from $52,500,000 to $101,000,000 for general expansion.

THE SCIENTIFIC CHEMICAL CO., 141 West 36th St., New York, N. Y., has arranged for an increase in capital from $100,000 to $3,000,000 for proposed expansion.

THE J. T. BAKER CHEMICAL CO., Phillipsburg, N. J., has filed notice of increase in capital from $150,000 to $500,000.

THE WEST DISINFECTING CO., 411 5th Ave., New York, N. Y., has filed notice of increase in capital from $250,000 to $2,500,000.

THE ACME CEMENT CORP., Catskill, N. Y., has arranged for an increase in capital from $1,350,000 to $2,800,000, for proposed expansion.

THE WILCOTT OIL CO., Shreveport, La., has increased its capital to $150,000 for proposed expansion.

THE THREE-IN-ONE OIL CO., Rahway, N. J., has filed notice of increase in capital from $100,000 to $1,000,000 for general expansion. The company specializes in lubricating oils.

THE CHELSEA FIBRE MILLS, INC., 212 5th Ave., New York, N. Y., manufacturer of fibre products, has increased its capital from $2,000,000 to $2,600,000.

THE GOSHEN RUBBER & MFG. CO., Goshen, Ind., has filed notice of dissolution under state laws.

THE STANDARD OIL CO. OF KENTUCKY, Louisville, Ky., has called a special meeting of stockholders, Dec. 21, to arrange for an increase in capital from $12,000,000 to $17,500,000, a portion of the proceeds to be used for extensions.

THE OSBORN PAPER CO., Goshen, Ind., has arranged for an increase in capital from $75,000 to $600,000 for proposed expansion.

THE GLIDO OIL & CHEMICAL CO., Buffalo, N. Y., has filed notice of increase in capital from $25,000 to $75,000.

New Companies

THE NATIONAL GLASS CO., INC., Bridgeport, Conn., has been incorporated with a capital of $50,000, to manufacture and deal in glass products, mirrors, etc. The incorporators are Harry Schwartz and Mitchell L. Stone, 18 Highland Ave., Bridgeport.

THE ACME ALUMINUM FOUNDRY CO., 814 West 75th St., Chicago, Ill., has been incorporated with a capital of $15,000, to manufacture aluminum, brass and other kindred metal castings. The incorporators are Harry L. Ferguson, Daniel J. Kelly and Robert C. Fingal.

THE STANHOPE CHEMICAL CO., Brooklyn, N. Y., care of E. A. Deutschman, 44 Court St., Brooklyn, representative, has been incorporated with a capital of $15,000, to manufacture chemicals and chemical byproducts. The incorporators are C. G. Unger, M. Kempfer and M. L. Nathanson.

THE FRIEDLANDER PAPER CO., New York, N. Y., care of Speiser & Speiser, 170 Broadway, New York, representatives, has been incorporated with a capital of $30,000, to manufacture paper products. The incorporators are B., L., and S. Friedman.

THE BELL CREEK BY-PRODUCTS CO., Montgomery, W. Va., has been incorporated with a capital of $50,000, to manufacture petroleum byproducts. The incorporators are F. E. Smart, J. E. Wilkerson and G. C Humphreys.

THE KYLOID CO., Grand Haven, Mich., has been incorporated with a capital of $100,000, to manufacture composition products. The incorporators are C. R., R. R. and Lionel Heap, all of Grand Haven.

THE AMERICAN WEEVIL EXTERMINATOR CO., Atlanta, Ga., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws with capital of $100,000, to canufacture disinfectants, fungicides, chemicals, etc. The incorporators are H. G. Bickmore, Henry Eyers and H. K. Smith, Atlanta.

THE ANCHOR OIL CO., Jersey City, N. J., care of the United States Corporation Co., 15 Exchange Place, Jersey City, representative, has been incorporated with a capital of $2,250,000, to manufacture petroleum products and byproducts.

THE ISLAND RIVER FLUORSPAR CO., Providence, Ky., has been organized under state laws to operate fluorspar properties and operate a commercial spar reduction plant. The incorporators are J. C. Cannaday, S. K. Holland and Thomas O. Long, Providence.

THE FEDERALOID CORP., Hoboken, N. J., has been incorporated with a capital of 10,000 shares of stock, no par value, to manufacture celluloid and other composition products. The incorporators are Busmarch C. Moore, Abraham Lieberman and Richard W. Gutheil, 15 Newark St., Hoboken. The last noted represents the company.

THE TENNESSEE RUBBER CO., Murfreesboro, Tenn., has been incorporated with a capital of $25,000, to manufacture rubber products. The incorporators are W. S. Winn, Albert D. McKnight and James M. Butler, all of Murfreesboro.

THE WHITE STAR CHEMICAL CO., New York, N. Y., care of W. J. Carey, 220 Broadway, representative, has been incorporated with a capital of $30,000, to manufacture chemicals and chemical byproducts. The incorporators are H. K. Copeland and J. H. Ennis, Jr.

THE CRESCENT TANNING CO., Boston, Mass., has been incorporated with a capital of 1,000 shares of stock, no par value, to manufacture leather products. Benjamin J. Kaplan, 209 Highland Ave., Winchester, Mass., is president and treasurer.

THE OHIO PORTLAND CEMENT CO., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws, with capital of $3,000,000 to manufacture cement.

THE CANTON REFRACTORIES CO., Canton, O., has been incorporated with a capital of $15,000, to manufacture firebrick and other refractory products. The incorporators are Frank E. Bamberger and Frank H. Haldeman, both of Canton.

THE W. H. GAGE GLUE CO., St. Louis, Mo., has been incorporated with a capital of $75,000, to manufacture glue and other adhesives. The incorporators are W. H., C. A. and L. F. Gage, all of St. Louis.

THE MIDWAY CITY GLASS CORP., Huntington, W. Va., has been incorporated with a capital of $50,000, to manufacture glass products. The incorporators are B. W. Walton and R. Taylor Morris, Huntington; and Daniel Howard, New Cumberland, W. Va.

THE CONTINENTAL CORK CO., Brooklyn, N. Y., care of W. N. Veceland, 150 Nassau St., New York, representative, has been incorporated with a capital of $35,000, to manufacture cork products. The incorporators are D. Blois and S. A. Germino.

J. B. CHAPPELL, INC., Philadelphia, Pa., care of Louis Freyling, Ridge and Conarroe Sts., Philadelphia, representative, is being organized under state laws to manufacture paints, oils, varnishes, etc. Application for a state charter will be made on Jan. 2. The company is headed by William H. Chappell and Walter Boshart.

THE GENERAL SUPPLY & CHEMICAL CO., 28 Woolverton St., Trenton, N. J., has been incorporated with a capital of $100,000, to manufacture chemicals, chemical byproducts, etc. The incorporators are Henry M. Tobin and Barnard A. Leyson.

THE SLICK SHINE CO., care of the Colonial Charter Co., Ford Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws with capital of $500,000, to manufacture chemicals and chemical byproducts.

THE LASCO SHELLAC CO., Bush and Severn Sts., Baltimore, Md., has been incorporated with a capital of $100,000, to manufacture shellac, varnish, paints, etc. The incorporators are Louis A. Stabler, H. Pierce Brawner and E. C. Frank.

THE MASSEY OIL & REFINING CO., Scottsville, Ky., has been incorporated with a capital of $100,000, to manufacture refined

petroleum products. The incorporators are W. E. Massey, G. M. Gausch and E. E. Shephard.

THE EMPIRE TIRE & RUBBER CORP., Trenton, N. J., has been incorporated with a nominal capital of $10,000, to manufacture tires and rubber goods, succeeding the company of the same name now operating a plant at North Clinton and Mulberry Sts. The incorporators are W. Hall Appar, 36 East State St., Trenton; William N. Cooper and Thomas H. Bradeley.

Industrial Developments

CERAMIC—Following a strike since Oct. 1 for a wage increase of 7 per cent, general ware operative potters have agreed to return to work at the former wage scale, and all chinaware plants at East Liverpool, O., Trenton, N. J., and other prominent pottery districts are reopening. At Trenton, eight plants are affected, giving employment to more than 1,500 workers, including the International Pottery Co., Maddock Pottery, Cook Pottery Co., Lenox, Inc., Mercer Pottery Co., Anchor Pottery Co., and two plants of the Greenwood China Co.

Following a 2 months' shut-down due to the operatives' strike, the Atlas China Co., Niles, O., has resumed manufacture, giving employment to about 250 men. During the idle period the company has made repairs in the operating machinery and a number of plant improvements.

Chinaware plants at Newell, W. Va., and vicinity are resuming production at full capacity following the termination of the strike of operatives. Orders on hand at the majority of the plants insure this basis of production for an indefinite period.

Despite the strike of the sanitary ware pottery workers, a number of plants at Trenton, N. J., in this line are maintaining production, and a number are declaring for an open shop. The Thomas Maddock's Sons Co. is increasing production and is now giving employment to about 50 per cent of the regular working force. The Trenton Potteries Co. is also advancing manufacture, and has served notice that unless former employees return to their work at once new operatives will be installed in their places permanently.

LEATHER—The Continental Leather Co. is increasing production to a full-capacity basis at its plants at Elkton, Va., and Bridesburg, Pa., following the destruction of its third tannery, at Augusta Springs, by fire on Dec. 2. The first two plants mentioned having been running under partial output and will now take care of the work of the Augusta Springs tannery until it is rebuilt.

Glazed kid plants at Wilmington, Del., are increasing production and plan to add to the present working forces.

The Castle Kid Co., Camden, N. J., is advancing operations at its local plant and is now running on a basis of about 800 dozen cabrettas and kids daily.

OIL—The Sinclair Consolidated Oil Corp. has completed a new casinghead gasoline plant at its properties in the Burbank field, Okla., and will place the unit in operation at once on a basis of 8,000 gal. per day.

Refineries in the Wichita Falls, Tex., district, heretofore discontinuing operations in cold weather, are maintaining full production at the present time and expect to so operate for a number of weeks to come.

The Pennok Oil Co., Tulsa, Okla., is increasing production at its properties.

The White Eagle Oil & Refining Co., Wichita, Kan., is advancing production at its oil refinery and will give employment to a larger working force.

IRON AND STEEL—The Mahoning Valley Steel Co., Niles, O., has arranged for capacity production, and will run the entire 8 mills at its plant for an indefinite period.

The Empire Steel Co., Niles, O., has placed 8 mills in service at its local plant and is adding to the working force.

A number of companies are suspending blast-furnace operations in the Youngstown, O., district. The Shenango Furnace Co. has blown out its 200-ton unit, leaving only one of three furnaces of this company in operation. The Brier Hill Steel Co., has discontinued at its Tod furnace.

The Woodward Iron Co., Woodward, Ala., is continuing capacity operations at its furnaces, and has placed one of the stacks on basic iron to supply heavy orders for this material recently received.

The Falcon Steel Co., Niles, O., has placed another mill in operation at its local plant, making five such units now in service.

The Donaldson Iron Co., Emaus, Pa., is continuing capacity production at its local works, and has recently advanced the wages of operatives 25 cents a day.

The Sloss-Sheffield Steel & Iron Co., Birmingham, Ala., has blown in the fifth blast furnace at its plant, following a short shut-down for repairs.

The Youngstown Sheet & Tube Co., Youngstown, O., has blown in its Hubbard furnace. The unit has been out of blast for a number of weeks past. It will run on basic iron.

Following its proposed schedule, the Reading Iron Co., Reading, Pa., has resumed operations at its puddle mill at Birdsboro, Pa., following a suspension for about 2 years. Employment will be given to about 125 men.

The Republic Steel & Iron Co., Youngstown, O., is maintaining full operations at its local plant, with eight mills in service on the new side.

The Slatington Rolling Mill Co., Slatington, Pa., has resumed operations at its plant, following a short suspension due to fuel shortage.

METALS—The Anaconda Copper Mining Co., Butte, Mont., has resumed operations at its Berkeley property, giving employment to about 400 men.

The Davies & Thomas Foundry Co., Catasauqua, Pa., has resumed production at its plant, following about a week's shutdown due to machinery breakage.

The International Nickel Co. is maintaining capacity operations at its Port Colborne, Ont., refining plant. The rolling mills at Huntington, W. Va., are also running under a heavy production schedule.

The American Smelting & Refining Co. has adopted a capacity schedule at its East Helena, Mont., works for the first time in about 24 months. Employment is being given to close to 500 men.

The United Verde Extension, Jerome, Ariz., is advancing production at its local plant. Since August the rate of increase in output has run from 250,000 to 300,000 lb. of copper per month.

MISCELLANEOUS—The Grasselli Chemical Co. has resumed operations at its plant at Terre Haute, Ind., following curtailment for a number of months past. Employment will be given to about 200 men at the present time, and this number will be increased at an early date. The company has adopted a rule to employ only American labor at the factory.

The West Virginia Chemical Co. has resumed operations at its sulphuric acid plant at Fairmont, W. Va., on a full-capacity basis, following part-time production for a number of weeks past. Practically all former employees are again at the works and it is expected to maintain the present schedule for an indefinite period.

New Publications

BOOKS

PETROLEUM: WHERE AND HOW TO FIND IT. By *Anthony Blum*. 367 pages. Published by the Modern Mining Books Publishing Co., Chicago. Price, $2.

The author of this book is a geologist and petroleum engineer, who for "a third of a century" has been "engaged in the location, development and operation of mines, in working out oil-bearing geologic structure, locating oil wells, drilling and equipping them and in the production of petroleum." He has had, therefore, an unusual experience to draw on for the preparation of this book, which purports to present the practical aspects of the oil business in a way that will interest the layman. The first part of the book deals with four general phases of petroleum—geologic, constructive, operative and commercial. The purely business aspects are to be found in Part V, under the heading of "Fiscal Features."

THE BUREAU OF MINES: ITS HISTORY, ACTIVITIES AND ORGANIZATION. By *Fred Wilbur Powell*. Institute for Governmental Research, Service Monographs of the U. S. Government, No. 3. Published by D. Appleton & Co., New York.

This is the third of a series prepared according to a uniform plan and in which will be described all of the principal services of the federal government. The purpose is to give, first, the history of the establishment and development of the service; second, its functions, described not in general terms, but by detailing its specific activities; third, its organization for the handling of these activities; fourth, the character of its plant; fifth, a compilation of, or reference to, the laws and regulations governing its operations; sixth, financial statements showing its operations, expenditures and other data for a period of years; and finally, a full bibliography of all the sources of information bearing on the service and its operations. These studies are wholly descriptive—no effort being made to discuss critically conditions and developments within the service. The present volume of 162 pages is a very interesting story of the Bureau of Mines.

A TEXTBOOK OF FIRE ASSAYING. By *Edward E. Bugbee*. 254 pages. Published by John Wiley & Sons, Inc. Price, $3.

The author states in his preface that this book is the outgrowth of a set of mimeographed notes prepared for use in the course in fire assaying at the Massachusetts Institute of Technology. While intended primarily as a college textbook, it is not entirely elementary in character and might well find its place in many industrial laboratories. Written on the assumption that a course in fire assaying is the logical place to introduce the study of metallurgy, the author has laid special emphasis on all of the metallurgical principles involved, such as the thermochemistry of the metals and their oxides, the nature and physical constants of slags, the characteristics of refractories and fuels and the behavior and properties of metallic alloys.

COLORIMETRIC ANALYSIS. By *F. D. Snell*. 150 pages. Published by D. Van Nostrand Co., New York. Price, $2.

It was the endeavor of the author of this book to supply students and practical workers in colorimetrics with all of the important methods and tests which they are likely to meet with in their work. The first chapters deal with the theory, apparatus and its use and the figuring of results. Important quantitative and qualitative determinations such as those for iron, copper, carbon, lead, aluminum, nickel, chromium, cobalt, etc., form the subjects of the other chapters.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold a meeting Dec. 26 to 30 in Boston, Mass.

AMERICAN CERAMIC SOCIETY will hold its annual meeting in Pittsburgh, Pa., Feb. 12 to 17, 1923.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting April 3 to 7, 1923, at New Haven, Conn.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting May 3, 4 and 5, 1923, at the Commodore Hotel, New York City.

AMERICAN ENGINEERING COUNCIL, executive organ of the Federated American Engineering Societies, will meet in Washington, D. C., Jan. 11 and 12, 1923.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its annual meeting in New York City during the week of Feb. 19, 1923.

AMERICAN SOCIETY FOR STEEL TREATING will hold its winter sectional meeting in the City Club, Chicago, Feb. 15 and 16, 1923.

INTERNATIONAL CHAMBER OF COMMERCE will hold its second general meeting in Rome, Italy, March 19-26, 1923.

NATIONAL FOREIGN TRADE COUNCIL will hold its annual conference April 25, 26 and 27, 1923, in New Orleans, La.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS, with headquarters in Chicago, will hold its spring convention in Cincinnati, April 18, 19 and 20, 1923. The major subject will be "Management Problems of the Smaller Plants."

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, East 41st St., New York City; Jan. 5 — American Chemical Society, regular meeting. Jan. 12—Society of Chemical Industry, Perkin Medal. Feb. 9—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting. March 9—American Chemical Society, Nichols Medal. March 23—Society of Chemical Industry, regular meeting. April 20—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting. May 4—American Chemical Society, regular meeting. May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting. May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.

Volume 27 | New York, December 27, 1922 | Number 26

The Centenary of Louis Pasteur

ON DEC. 27, one hundred years ago, LOUIS PASTEUR was born at Dôle, France. His father, JOHN JOSEPH, like his grandfather and great-grandfather, was a tanner. He had also served as sergeant-major under NAPOLEON in the Peninsular campaign, and for it he bore the Cross of the Legion of Honor. There is a legend that he made his own gunpowder in the mountains of Spain, and that old men and women and children followed him and acted as his scouts against the dreadful guerilla commander ESPOZ Y MIÑA. JOHN JOSEPH married JEANNE ETIENNE ROQUI; and of her people, who were plumbers and lampmakers at Salins, it is said that they lived in such amity and good will in their families that "to love like the Roqui" became proverbial.

Their son LOUIS was a good boy. He was deeply religious throughout his life, following ardently the Roman Catholic faith. A deep student, his father frequently urged him not to endanger his health by studying too hard.

But what was the key to his greatness? He showed no sign of brilliancy as a boy. Like JOHN JOSEPH, LOUIS had a taste for drawing and painting, but he was in no way unusual. Many persons are pious and good, although there was only one LOUIS PASTEUR. We think the key to his greatness lay in his passion for work and in the principle which he often repeated: "In the field of observation, chance favors only those who are prepared." He prepared for chemistry by studying and digesting mathematics, physics and crystallography. He urged constantly the aid of physics and crystallography in chemistry—which sounds modern.

Let us follow his work on tartaric and paratartaric or racemic acids. Early as a student of organic chemistry he had been interested in MITSCHERLICH'S work on these bodies and the problem that even that scientist could not solve. The acids seemed identical in the nature, number and arrangement of their atoms, and yet tartaric acid rotated the plane of polarized light, while paratartaric acid remained inactive. Later PASTEUR learned from his friend LAURENT that crystals of very pure sodium tungstate proved, on microscopic examination, to be of three different forms. He published a paper on the rotary polarization of liquids and one on dimorphism, and returned after the interruption of the revolution of '48 to the tartaric acid study. Finally he observed that crystals of tartaric acid and of the tartrates had little faces which theretofore had escaped the attention of observers. They existed on only half the edges or similar angles of the crystals; they were hemihedral in form. He reasoned that this would account for the deviation to the right of the plane of polarization as caused by the tartartes. On the paratartrates he expected to find none of these faces. But alas! close observation proved the paratartrate crystals also to be hemihedral, which was a sore disappointment. Right here we may note the quality of PASTEUR'S genius. He did not stop; and he was prepared. The paratartrate crystals were indeed hemihedral, but the faces of some of the crystals were inclined to the right and of others to the left! Then he sorted them out, one by one, and proceeded with their respective solutions in his polarizing apparatus—and the problem was solved. The hitherto incomprehensible constitution of racemic acid was explained. There was the right-hand tartaric acid, which is the same as that obtained from grapes, and a left-hand acid. The two acids have equal but opposite rotatory powers which neutralize each other when, reduced to an aqueous solution, they are present in equal quantities. There was MITSCHERLICH'S problem solved and the real beginning of stereochemistry.

When we think that in addition to this PASTEUR gave us our understanding of ferments, which promises even greater economies in organic chemical industry; that he discovered the underlying principles of vaccination; that he was the father of biology; that he saved the wine and silk industries of France, put an end to chicken cholera, gave us a vaccine for anthrax and conquered rabies, there is little wonder that a hundred years after his nativity the banners are waving in his honor and we meet to sound his praise.

Absence of Gas Casualties In Military Hospitals

A LARGE part of the propaganda that has been used to create sentiment against chemical warfare has dealt with mysterious gases that have not yet been used, but to which the most deadly character is ascribed. Alleged authorities who, in our opinion, are quite incompetent are quoted in support of the assumption that future methods of warfare will be quite as ruthless as the gases are deadly, and that non-combatants in defenceless towns will be asphyxiated by the million while they sleep. Apparently there is no limit to the imagination of those who draw these gruesome pictures. They wholly disregard the probability that non-combatants will be quite as safe from gas attacks as they now are from long-range artillery and that due warning probably would be given for the evacuation of cities before wholesale destruction was attempted. In short, our friends are creating needless worry for themselves and are crossing bridges long before they are reached.

There are more salient features of chemical warfare to be observed in the casualties of the late war. The argument has frequently been made that chemical warfare was more humane, or, better, less inhumane, than the older and recognized methods. In support of this contention we commend to our anti-chemical warfare enthusiasts a study of the war casualties still receiving attention in military hospitals. The number of gas cases will be found so small as to be negligible, while

the great majority will bear direct testimony to the horrible and inhumane effects of gunfire—shrapnel, high-explosive shells, machine gun and rifle bullets. Eliminate explosives from warfare, and most of the mutilation and maiming of human bodies will disappear. Whatever may be its demerits, gas warfare will not fill post-war hospitals with the casualties of armed conflict. Today there are approximately 20,000 men under treatment in government institutions due to war wounds or disability in military service, but an insignificant and negligible number of these cases are the consequence of gas warfare.

Asking for Bread And Getting a Stone

IT WOULD be impossible as well as futile to pay serious attention to all of the examples of newspaper science that come to our notice, either personally or through the interest of our readers. Most of the specimens merely exhibit laughable ignorance on the part of the reporter or the omniscient conductor of the question and answer column. Occasionally, however, we run across an instance that, in the sheer interest of public safety, calls for exposure and condemnation. We can remain undisturbed or only mildly amused when a newspaper reader is told that sulphuric acid is used largely as an anæsthetic in surgical operations, because we know that the overworked editor strayed into the wrong paragraph in his book of handy reference on scientific subjects. But when an anxious inquirer asks how to make a home-made fire extinguisher and is given a recipe for gunpowder, we protest that the joke is being carried too far.

Being more than merely curious to discover how such misinformation could be dispensed through the columns of reputable newspapers, we pushed the inquiry to a final conclusion. It seems that a central "information bureau" established in the national capital syndicates its service to a number of newspapers in answer to queries that are forwarded to it. The bureau receives several thousand queries a week for information of various sorts. Answers are prepared by a corps of young ladies who depend largely upon government sources of information. But occasionally it is much easier and requires far less time to consult a handy reference work than to make a trip to a government office or try to extract the information by telephone. This is exactly what happened in the gunpowder-fire extinguisher incident. Reference was made to a popular cyclopedia of formulas, and the unsuspecting inquirer was advised to procure "potassium nitrate, 60 oz.; sulphur, 36 oz.; charcoal, 4 oz., colcophar of rouge, 1 oz. Powder separately, dry and mix. This powder is used by placing it in 5-lb. pasteboard boxes, through an orifice in which a fuse is inserted. An extinguisher so made is intended for use in a closed room. It is supposed to act automatically by absorbing oxygen." In the interest of accuracy it must be recorded that the cyclopedia in announcing the formula, stated that "by a slight modification of it we have a recipe for making gunpowder," a bit of information omitted by the newspaper. But even with this saving grace the item is about as useless a piece of information as can be imagined. It is to be hoped that the one who made the inquiry has not yet attempted to use the extinguisher, because if he does he is likely to accelerate rather than extinguish a fire.

No doubt many such examples of newspaper science and misinformation occur in a year, though probably few of them are fraught with possible consequences as dangerous as this one. Chemists and engineers generally should be on the lookout for such items and report them to responsible heads of newspapers publishing them. Conversely newspapers should be encouraged to use the maximum amount of reliable scientific information and advised that local scientists will be glad to assist them in avoiding ludicrous or costly errors.

A Working Balance In Industry

IN ONE of its recent editorials our friend and contemporary *Canadian Chemistry and Metallurgy* very skillfully likens the long-standing controversy of the practical versus the technically trained man in industry to the famous question that Gulliver put to the Lilliputions—viz., Which is the more important end of an egg, the little end or the big end? And just as the conflicting armies of Lilliput forgot that the important thing is the egg itself and not its physical details, so the two parties involved in the other quarrel have lost sight of the fact that they are interdependent and that neither the practical nor the technical man is self-sufficient. Industry depends on both of them and its particular problem is to maintain the sort of balance that promotes co-operation and progress.

We are reminded of a large company in one of our industries that has given serious study to this special phase of human relations. As a result the company boasts of a number of unusual features in its organization. In the first place, its president is a chemist whose name is known to every worker in the industry. So, too, are the general manager of the company's largest works and many of the department heads. Perhaps this is one of the contributing reasons why in the past the company has found it difficult to keep its chemists in the research and control laboratories, so great has been the temptation to enter into operating and executive work. As more and more men left the laboratory it was evident that many of the practical men who had come up from the ranks were being crowded out of positions for which their experience had well qualified them. It was then that the company took notice of this situation and evolved a plan of maintaining what might be called a sort of working balance in industry.

It was decreed that in each department of the plant control should rest with a committee of three men, the superintendent and the two assistant superintendents. One of these men must be a chemist, one must be a practical man drawn from the department's operating personnel and the third must be a mechanical engineer, since in this particular industry much depends upon the construction and maintenance of complicated engineering equipment and apparatus. Instead of crowding out the non-technical man, as previously was the case, this plan opens up a definite pathway for him. He has the opportunity not only to become head of his department but by promotion he may be raised to general manager of the plant or perhaps even to the head of the great organization itself. Likewise the chemist is given a chance to come out of his laboratory shell and to compete for the real plums of his industry.

From the company's viewpoint much is to be gained. The practical man puts to use valuable knowledge and experience gained by hard work and close contact with production. The technically trained man brings a knowledge of basic scientific principles and, more than that, a broadened viewpoint that helps to apply these principles of science to industry. When the proper bal-

ance is reached and these viewpoints are mixed in the right proportion, the industry must prosper. And if we are to judge the effectiveness of this plan by the success of the Standard Oil Company of Indiana, then there are many companies in our industries that would do well to follow this example.

Numbering Of Steel

SPURRED by the activities of the American Engineering Standards Committee, men representing a wide variety of interests recently met in Washington to consider whether it was possible to designate steels by code numbers. That some such scheme would be desirable is generally admitted. In the good old days of straight carbon steels, it was very nice to call them No. 1 temper, No. 2 temper and so on—carbon was the important, the only alloy.

"No. 4 temper" failed to mean anything much when 3 per cent of nickel was added to the metal, so the Society of Automotive Engineers has devised a system of numbering which includes information on the amount of principal alloying element. Such a steel under its nomenclature would be S.A.E. steel 2340. The system is of great value, as is proved by its wide use. So it is rather idle to argue that the steel might better be called 3N40.

But steels of constantly increasing complexity are being offered. The logical system rapidly becomes unmanageable for nickel-chromium steels, with variations in three essential alloys, or for tool steels with four or more. Here lies the advantage of the arbitrary class number adopted by the S.A.E. Nickel-chromium steels are class 3, and tungsten steels are class 7. But even such an artifice has its limitations. Designation 3240 indicates about 2 per cent nickel and 0.40 carbon, but to get any idea of the third essential element, reference to the specification itself must be made.

In passing, it might be remarked that a similar difficulty exists in non-ferrous metallurgy. It is easy to designate deep-drawing brass by 70:30 or naval gun metal by 88:10:2. These are relatively simple combinations of common alloying elements. Several such alloys are standard articles of commerce under well-known names such as admiralty metal or sterling silver—we almost said nickel silver, but reference to a recent list of alloys showed no less than 165 varieties of this! If there is as much difficulty in the designation of time-honored combinations, what is the manufacturer of modern quaternary alloys to do except invent and trademark some word or symbol like duralumin, lynite, 17-S, or Y?

If a logical code indicating the chemical composition of steels and alloys has so far eluded discovery, how much more difficult will it be to devise one which in addition will denote that physical property which, after all, is what is desired and which the chemical composition indicates only dimly. For instance, a steel with 3 per cent nickel (usually $3\frac{1}{2}$ to $3\frac{3}{4}$) and carbon 0.35 to 0.45 is used for heavy forgings, propeller shafts and gun tubes, for gears of moderate size, connecting rods for locomotives, steam and gas engines, and for rolled structural shapes and bars for long span bridges.

There may not be room for argument that S.A.E. 2340 is a neater way to designate this particular composition than 49S2e, class HG, favored by the U. S. Navy. But proponents of simplified practice in metallurgy should always remember that 3Ni-45C-etc. is only incidental. What an ordnance constructor wants is not a chemical analysis, but a gun tube, and reference to his specification shows that the important thing he is after is high strength and ductility in a direction transverse to the "fiber." Bridge engineers, on the other hand, insist on considerable strength and toughness and reliability in a direction *with* the "fiber"—parallel to the rolling. An automotive engineer designing a gear would be interested in toughness, but probably more in resistance to wear and machinability. Finally, the master car builders or mechanical engineer interested in locomotive connecting rods would require stiffness and resistance to fatigue.

How are you going to get all this into one code without resorting to Chinese characters? The point we are driving at, of course, is that the only known way to describe a steel is in a detailed specification, and even that leaves a great deal to such indefinable items as "judgment" and "good practice." So it makes no great difference whether a steel is called S.A.E. 2340, Navy Department 49S2e, or A.S.T.M. A 8-21, as long as the specification is definite and workable. All of the steels might be indistinguishable chemically; but as one might remark, "Good steel is more than low phosphorus and sulphur."

A Lesson From the A.S.M.E. Convention

DOUBTLESS the readers of *Chem. & Met.* are not accustomed to look to the American Society of Mechanical Engineers for constructive thoughts or helpful ideas in the conduct of the chemical and related industries. It is well, however, to remember that the mechanical engineer is so intimately associated with industry in general that the trend of thought in his national organization is likely to merit the careful consideration of industry as a whole. Witness the campaign of two years ago for the elimination of waste in industry, the keynote of which was sounded at an A.S.M.E. convention. At this year's meeting the keynote was "Economics for Engineers," the A.S.M.E. having joined with the American Economic Association in directing the attention of engineers to the study and application of the broad general principles of the science of economics.

Has this intimate relationship any significance for us as chemical engineers? Does it mean only a combination of mechanical engineering and economics, or does it include engineering in its broadest and most inclusive sense? Obviously the latter. The mechanical engineers are merely giving belated recognition from their branch of engineering to the fact that engineers and economists have many interests in common and that both must contribute to the real end of engineering, which is "the art of organizing and directing men and controlling the forces and materials of nature for the benefit of the human race." With this fact clearly in mind, the mechanical engineers have set about recasting their mode of thinking so that the principles of economic science may be given proportionate weight in the solution of engineering problems.

The importance of recognizing this relationship is as great in the chemical and related industries as in any other field of human endeavor. The present need of industrial management here as elsewhere is the recognition of fundamental economic truth, and however belated we may be in realizing this condition, it behooves us to bear the point in mind and encourage economics and technology to travel side by side.

Chemists in Public Life

To the Editor of Chemical & Metallurgical Engineering

SIR:— In your note following the letter on "Appreciation of the Engineer" in *Chem. & Met.* of Nov. 29, when noting the versatility of the engineer and chemist, you fail to recall any noteworthy instance where they have become well known in religious activities. It is well worth mentioning that Dr. Jesse H. Holmes, professor of philosophy and religion of Swarthmore College, received his doctorate in chemistry, with minors in biology, physics and mineralogy, and until 1900 Dr. Holmes spent a number of years in teaching these sciences. Since 1900 he has been teaching philosophy and history of religions, including the study of the Bible.

Why Not Get Away From Traditions?

To the Editor of Chemical & Metallurgical Engineering

SIR:—Why not get away from traditions? Because they are the instruments used in constructing the framework of our social, economic and industrial structures. They are experience.

To the outsider the reason many things are done in industry is obscure. Usually digging deep enough will uncover a sound reason, based probably on experience. Neither the workman himself nor anyone immediately available may be able to give the real reason. Likely as not if asked he will give a wrong explanation.

I presume in the case of the reel oven mentioned in your issue of Nov. 29, it was built with the object of giving what the baker terms a "solid heat." One does not read of "solid heat" and "flash heat" in works on thermodynamics, but they are important nevertheless.

I knew of a reel oven built for breadmaking which had a steel shell covered with insulation; no brickwork at all. In using this it was demonstrated beyond doubt that in order to have the finished loaves weigh the same as exactly the same kind of loaf baked in the ordinary oven of heavy brickwork, it was necessary to allow from a half to one ounce additional weight of dough to each loaf when scaling. And at this time one big bakery was operating at a net profit of one mill per loaf. The significance of this is apparent.

Now as to apparent conservatism. A few years ago the proprietor of one of the big bakeries in the United States said to me, referring to a new type of oven he had installed about a year before: "I'm tearing them out. They're one of the best ovens I ever had, but I can't get them run properly. I have had nothing but trouble with them since I installed them. I can get plenty of men to run the older type as they should be run and I'm going back to them." Here was an instance of a simple type, less efficient, actually producing more satisfactory results than a more efficient one requiring greater skill to produce the best results.

Few industries have made greater advances in the past 40 years than the baking industry. From a trade where mechanical equipment was practically unknown, it has developed until the manufacturing end of a modern baking plant is almost automatic. In at least one year of recent date, statistics show that the baking industry showed a greater return per dollar invested than any other industry in the United States. This affords a pretty fair indication that it has measured up to its opportunities.

The outsider frequently can and does suggest valuable improvements because the man inside is too close to his work to view it in the proper perspective. But sometimes the man inside looks out. A progressive baker wished to eliminate unsightly cracks which, in his eyes, marred the surface of one line of his goods. What suggested a remedy? His observation of the practice of anealing bottles in a glass factory.

Treat that man with suspicion who can "see at a glance" opportunities for improvement. By no means disregard him, but discount him heavily. Improvements can be effected in any plant at any time. Many such which at first sight appear promising prove on closer acquaintance impracticable. Against this appears the unaccountable psychological fact that the same suggestion for improvement that is refused when advanced by the insider is given consideration and executed when put forward by an outsider. Truly a prophet is not without honor save in his own country.

Why does the operating staff in some chemical plants today feel that a specially warm place in the hereafter is reserved for the engineer who designed and built the plant? Isn't it, oftener than not, because the engineer tried to get away from traditions? And when the plant is turned over to the operating crew, where is the engineer? Gone elsewhere, getting away from some more traditions, probably.

"Tradition," says Webster, "hands down the practical arts with more precision and fidelity than they can be transmitted by books." Nothing could be clearer than that. As a rule in the arts the one who really knows cannot and does not express himself in writing. Conversely, the one who writes seldom does so from experience.

Don't try to get away from traditions. They are the tools which countless hands have forged and striven to improve down through the centuries. Master the use of them. With an intimate knowledge of them will come an appreciation of their value. Then, if you can, add to their beauty and utility.

Whitby, Ont. MUNGO E. NASMITH.

Rate of Settling of Clay Suspensions

The rate of settling of clay is thought to be an important matter in connection with the use of clays as a filler in papermaking. The rate of settling of clay in a medium is to a certain extent dependent on the hydrogen-ion concentration of the suspending medium. The rate of settling of six clays has been studied over a wide range of hydrogen-ion concentrations. For each clay-water mixture, there is a definite hydrogen-ion concentration at which the rate of settling will be a maximum, and also a definite concentration at which this rate is a minimum. In the purification of clay, these two points should be known in order to effect the separation of clay particles from quartz and mica particles most efficiently.

Art and Science of Leather Manufacture—II

By F. L. Seymour-Jones

Preliminary Wetwork: Soaking, Sweating, Loosening Hair by Enzymes, Acids and Liming, Sharpening Agents, Unhairing, Fleshing, Deliming, Drenching, Puering and Bating, Scudding, Pickling—Rounding—Splitting*

IN WHATEVER WAY a hide or skin enters a tannery, the first step is to restore it to as near its original condition as possible. In olden times this was accomplished by pegging down the hides in the tannery brook and permitting them to remain there until sufficiently softened. River pollution laws and the loss of hide substance in such a process have caused this method to be abandoned.

Washing or Soaking to Restore Original Condition

Fresh hides are washed in several changes of cold, fresh water, to remove all blood and dirt and to cleanse the hide thoroughly, no special treatment being necessary. A few hours is sufficient; long soaking, or the use of warm or stale water, leads to putrefaction and much damage.

Salted hides require longer soaking, not only to remove the salt but also to plump the fiber so that it may regain its original condition after the dehydration effected by the salt. Longer soaking is possible, owing to the antiseptic powers of the salt. Usually 3 to 4 days' soaking, changing the water at least daily, and preferably with frequent handling (i.e., hauling the hides out and replacing) is adequate. Frequently the soaking is completed by running the hides in a wash wheel—an open-sided drum, through which a stream of water passes—for a few minutes. Salt is, of course, readily soluble in water, and will diffuse the more rapidly the more often the water is changed or the hides handled.

Dry salted and dry hides require more drastic treatment, and are frequently very difficult to soak back into suitable condition. Putrid or stale soaks were largely used, and are still occasionally to be found. In these the dissolved organic hydrolysis products from the hides are permitted to accumulate, and exert—probably by providing suitable nutriment for bacteria—a softening action on the hide. Naturally the danger of damage by bacterial action is great, and hides so treated are liable to much loss of valuable leather-forming hide substance.

Putrid soaks have largely been replaced by the use of chemicals. A great variety have been suggested. Probably the best are dilute organic acids (e.g., formic) or sulphurous acid up to 2 per cent strength. The hides are treated in these liquors for 1 or 2 days, whereby they are swollen and well plumped. Caustic soda (0.1 per cent) and sodium sulphide (up to 0.5 per cent) are largely used, and exert also a preliminary liming effect.

Mechanical Softening

The chemical softening is frequently accompanied also by mechanical softening. For hides the faller stocks are used, kneading and pounding the hide. Skins are frequently "worked on the beam"—i.e., stretched and worked with a blunt knife on a curved-surface table. Both hides and skins may also be tumbled in water in a revolving drum, the mechanical action greatly facilitating the softening (Fig. 5).

The chief danger in soaking, apart from too violent stocking, lies in bacterial action in the soak waters. As previously mentioned, the majority of common disinfectants are barred owing to their tanning action. Sulphurous acid, very dilute phenol, and borax are used as antiseptics here. Even with dilute carbolic acid, the subsequent liming is slowed down considerably. Borax is somewhat costly.

Methods of Removing Hair or Wool

The hides and skins having been brought back to a softened condition, the next operation is to remove the hair or wool. While hair is a byproduct of only small value, the wool of sheepskins is normally of considerably greater value than the pelt, and consequently more care is taken in preserving it than in looking after the skin.

The oldest method of removing hair or wool is that known as sweating, in which a mild putrefaction develops. The hides or skins are hung up in a closed chamber, known as a sweat pit, maintained at an even temperature by double walls or other suitable means. The temperature is kept at 15 to 20 deg. C. by means of steam pipes below the lattice floor, and cold water sprinklers so placed that they do not play on the hides. The air is thus kept saturated with moisture. There is practically no ventilation, and the ammonia liberated by the putrefaction plays a considerable part in loosening the hair. The stench from sweat pits in full operation is terrific, and here lies one cause why tanning in many countries is classed as an offensive trade.

Wool skins (sheep) are treated in a similar manner, a somewhat higher temperature being used. The proc-

FIG. 6—HIDES ROPED TOGETHER OR TOGGLED PRIOR TO REELING IN LIMES

ess is then known as staling. The whole process necessitates very careful supervision to insure that hides are removed before putrefaction has gone too far; otherwise irreparable damage to the grain ensues. In some cases much damage to pelts has been caused by nematode worms during the staling of sheepskins.

While with very careful control sweating offers the advantage, for heavy leather at least, that comparatively little hide substance is lost, its merits are greatly outweighed by the danger of damage to the goods and the excessive and close supervision necessary. Consequently it has very largely been abandoned, and is now used only occasionally for heavy hides, though still to a large extent for sheepskins.

One recent scientific innovation for unhairing is the use of enzymes. A preparation, in which trypsin is the active constituent, has been placed on the market under the name of Arazym. It works quite effectively, though further investigation is necessary to elucidate the nature of enzyme unhairing. Trypsin readily dissolves the young keratin of the hair roots and lower portion of the epidermis, but does not so readily attack the collagenous matter of the true skin unless present in fairly large concentration. Work is in progress along these lines in several laboratories at present, and interesting results may be expected in the course of the next year. Dr. H. C. Ross, working in England, recently patented the use of thrombase for unhairing. Since thrombase is an enzyme developed naturally in the skin itself, this process promises to be of much interest. It is still too recent to permit of any discussion of its practical value.

Another old method of unhairing, which has spasmodically attracted the attention of chemists in recent years, is by the use of dilute acids. A hundred and fifty years ago it was common to unhair in spent, fermented tan liquors, or in barley or grain mash. The process was superseded by the more simple and foolproof method of liming. Acid unhairing is effective, but there is danger that the grain membrane may also be split off from the skin in the form of blisters. The proper conditions for its safe working have not yet been developed.

The standard method of depilation consists in the use of solutions of lime, with or without sharpening agents such as sodium sulphide, sodium hydroxide, arsenic sulphide, etc. Straight limes (i.e., saturated solutions of slaked lime) unhair very slowly under sterile conditions, and there is no doubt that bacteria in the limes, together with degradation products from the hydrolysis of the keratins of the skin (also those from the hide substance), play an important part in unhairing.

There are endless ways of working the limeyard, of which one or two typical may be outlined. The three-pit system is perhaps the most common. In this the hides pass first into an "old" lime liquor (twice before used), then to a medium lime (once used) and finally to a fresh lime. The liquors are always kept saturated, an excess of solid calcium hydroxide being in the pit. The hides are placed in the pit flat, and are hauled (drawn out) and set (replaced) at frequent intervals to hasten the process. Frequently they are roped together, end to end, and reeled over a pulley from one pit to the next. (Fig. 6.) A limeyard in which the packs of hides are handled with an electric traveling crane is shown in Fig. 7.

In another method one pit only is used; the liquor is bettered from time to time by the addition of fresh lime. In this way hydrolysis products tend to accumulate in the lime, providing a fertile culture medium for those bacteria which flourish in lime liquors. Formerly such pits were rarely cleaned out. The three-pit system offers distinct advantages in that the spent liquor is run off after three packs.

Sodium sulphide is now almost universally added to hasten the unhairing action. In water this substance hydrolyzes to form equimolecular proportions of sodium hydrosulphide and hydroxide. Stiasny showed 16 years ago that so long as the proportion of hydroxyl ion to hydrosulphide ion exceeded unity, the unhairing action was good, the optimum being at unity. Where hydrosulphide ion is in excess, unhairing is poor. Consequently when used alone the water used must be soft; otherwise part of the hydroxyl ions are removed in softening the water, and the ratio $[OH]^-:[SH]^-$ becomes less than one, and unhairing is slow.

Sodium sulphide used alone has a very powerful solvent action on the epidermis and hair, and further draws the grain up into rucks. Its use in this respect is usually confined to cheap classes of skins. These are either dipped for a few minutes into a very concentrated solution, or a lime-sulphide paste is swabbed on the flesh side, and the skins piled. The hair can then be brushed off—the brush being made of fiber—or washed off in a wash wheel.

Used in conjunction with lime, the sulphide is employed in dilute solution, 2 oz. per hide being usually sufficient. It is impossible to give exact quantities, as practice varies so enormously.

The use of arsenic sulphide is almost entirely confined to goatskins and the finer quality of sheep. It is

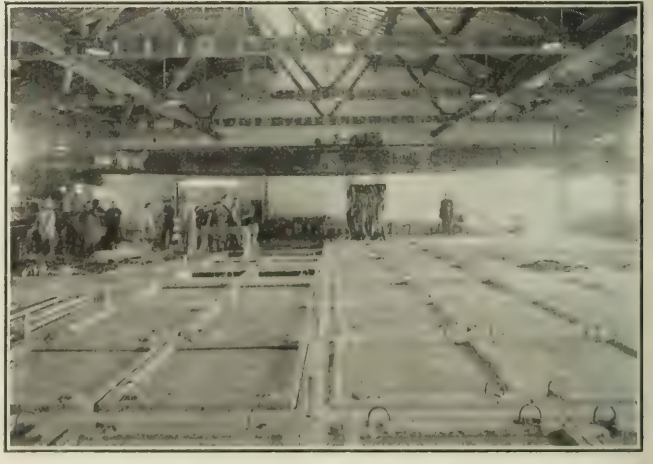

FIG. 7—LIMEYARD WITH ELECTRIC TRAVELING CRANE

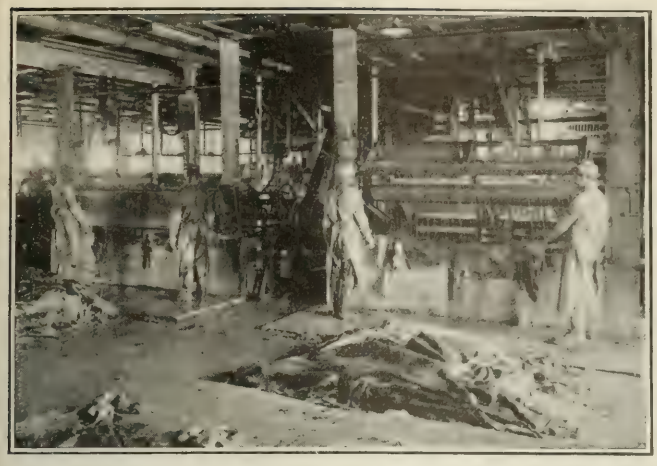

FIG. 8—UNHAIRING WHOLE HIDES

slaked in with the lime, the reaction being highly complicated and the products variable, according to the amount of arsenic used, temperature of slaking, etc. There is no doubt that it provides a finer grain for glazed kid and similar leathers. But it is probable, in the light of recent research, that the result might be obtained by other and cheaper means. The object is to insure that calcium, rather than sodium collagenate, is formed in the limes, by combination between the kation and the skin protein, in accordance with Loeb's work.

Other alkalis can be used for unhairing. Sodium hydroxide swells and plumps (renders firm) the pelt, but unhairing is slow unless the solution is concentrated,

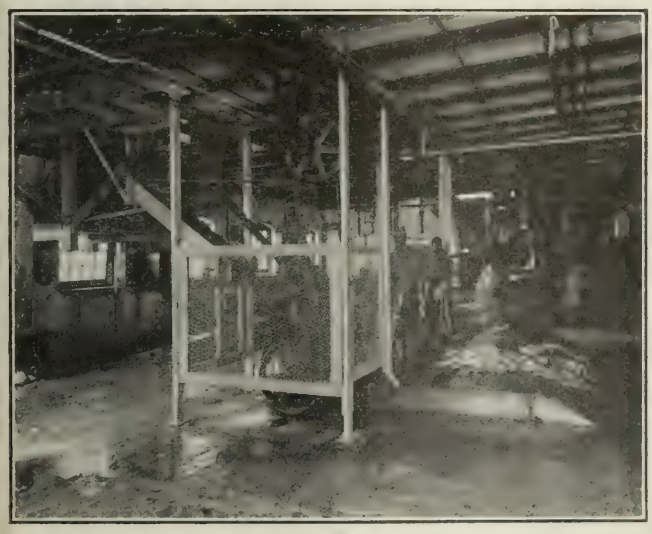

FIG. 9—FLESHING

when the hair is dissolved off. Ammonia readily unhairs, but does not swell or plump the hide. Lime is in general the most suitable. It has very limited solubility and consequently excess can be used with little danger of subsequent damage. It is as near a foolproof material as is possible under technical conditions, although it is by no means difficult to ruin goods in the limeyard.

Stiasny's work showed that liming effects depended largely on the concentration of hydroxyl ion. Consequently anything which can, by interaction with the lime, increase this, will act as a sharpening agent—e.g., sodium oxalate, sulphate, thiosulphate, etc.

The time and nature of liming vary according to the nature of product desired. For sole leather, where a plump, firm product is the object, liming is short and sharp, to loosen the hair and plump the goods. For dressing and harness leather, more mellow liquors are used, to open up the goods to a greater extent. Generally the time varies from 1 week to 3 weeks.

Sheepskins, if they come from a fellmonger (wool puller), have usually been preserved in "gathering limes" after the removal of the wool. Consequently the time of liming will vary according to the amount they have previously received.

FIG. 10—TRIMMING ON THE BEAM

Temperature also plays a part in liming. Although lime is more soluble in cold water than in hot, this is offset by its increased action at higher temperatures. From this a liming process has been devised. Hides are given a very short liming in a lime-sulphide liquor, then pass to warm water (35 to 45 deg. C.) for 12 hours or so, after which they can readily be unhaired.

An ingenious chemical method was devised by Pullman and Payne. The hides are treated first in a sodium hydroxide liquor, followed by a calcium chloride liquor, the object being the formation of lime in the skin. Unless the goods have been treated in a putrid soak, they will not unhair by this method. This process is advantageously used for tanning skins with the hair or fur on.

Various mechanical devices have been brought for-

FIG. 11—INSPECTION BEFORE TANNING

FIG. 12—DELIMING IN DRUMS

ward for hastening liming. A revolving paddle below a false bottom is effective, though likely to be choked by the excess of solid lime. Circulating the liquor with air blast (Forsare process) and suspending the hides combined with a rocking motion (Tilston-Melbourne process) are recent innovations and have met with some application in England. At the limeyard shown in Fig. 6 each vat is thoroughly stirred or plunged with compressed air just before reeling in a string of hides.

From the foregoing it will be seen that liming accomplishes more than merely loosening the hair. With sharp, caustic limes, the hide is swollen and plumped, and the fibers opened up to receive the tan more readily. Long mellow liming tends to remove the interfibrillary substances, and hence to soften the pelt. Greasy skins, such as pig and sheep, have part of their grease converted into lime soaps, whence it is removed by subsequent scudding. There is much to justify the saying that good leather is made before it enters the tanyard.

Unhairing, Fleshing and Deliming

The loosened hair is removed by hand, with a blunt knife over the beam, or, more generally, by machine. One common type consists of a revolving roller fitted with spiral knives which sweeps down a rubber or pneumatic bed on which the hide is laid. Fine hairs are often deep rooted and resistant, and frequently have to be removed afterward by going over the hide with the hand knife. Fig. 8 illustrates the unhairing of the whole hides by machine.

Fleshing may precede or follow liming. In this process all flesh, fat and tissue adhering to the flesh side of the hide are removed, either by hand over the beam with a knife or by machinery. Various types of machines have been developed. All have spiral knifed rollers, against which the hide is pressed by a pneumatic roll, a semi-cylindrical beam, etc. It is usually necessary to finish this operation by hand on the beam. (Fig. 10.) A thorough inspection often follows (Fig. 11) before the hides enter the tanning liquors.

Since all tanning is carried out in an acid medium, and lime precipitates nearly all tannins, it is necessary to remove lime from the skins before proceeding further. For sole leather a surface deliming is often sufficient, while for lighter leathers all lime must be removed to reduce the swelling of the skins and render them soft and flaccid.

The straight chemical process consists in the use of acids. The hides or skins are first washed with water, but removal of lime by this means is slow and always far from complete. Boric acid is used to a limited extent; it is very safe and suitable but somewhat expensive. The common mineral acids, sulphuric and hydrochloric, find most application, but have to be used with care. Excessive concentration of acid (even "dilute" acid) gives a very strong and undesirable swelling. The stock is usually suspended, drummed or paddled, and the acid added very slowly. Organic acids, acetic, lactic, formic, butyric, etc., are being increasingly used with advantage, the chief objection to them being their cost. Even these must not be used in excess. Where skins are being tanned to last for many years (e.g., bookbinding leather), it is essential that *all* treatment with mineral acid be avoided. In the course of time these rot and decay the leathers, leading to that peeling and rubbing away of leather-bound books so familiar today. Many acids of the aromatic series have been suggested, and have a certain antiseptic action, but they have met with little general application. Sulphuric acid, used with caution, is still the most general.

The use of drums and paddles is illustrated in Figs. 12 and 13 respectively. Fig. 13 also gives a closer view of the crane shown in Fig. 7.

Drenching, Bating and Puering

Drenching, though it usually follows (and occasionally replaces) bating, is strictly a deliming process. The drench consists of a fermented infusion of bran, the active agents being *bacterium furfuris* α and β, isolated by J. T. Wood. The cerealin of the bran produces glucose from the starch present, which is in turn attacked by these bacteria. Much gas is evolved, chiefly hydrogen, together with carbon dioxide and nitrogen. Lactic and acetic together with smaller amounts of formic and butyric acids are formed, and these exert the deliming action.

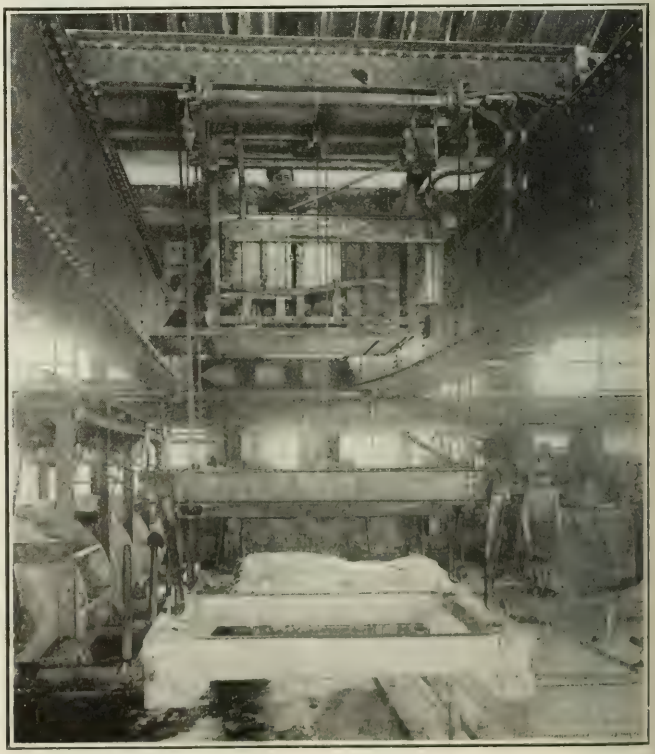

FIG. 13—DELIMING WITH PADDLES

The process is confined to skins, which are drenched in pits, being permitted to rise to the surface, and paddled or poled down again. The temperature is kept about 30 deg. C., and the process lasts 12 to 24 hours. The bran particles have a scouring and cleaning effect on the pelt.

Drenching must not be carried too far, otherwise small blisters form on the grain of the skin, due to the evolution of gas *in* the skin substance. In thundery and sultry weather the drench is apt to sour very rapidly. Some noxious fermentation sets in, and the skins rapidly become glassy and fall to pieces. The cause of this is still obscure.

In no process in the whole of leather manufacture has science done more to improve matters than in bating. Strictly speaking, bating consists in treating hides with infusions of fermented hen and pigeon dung, and puering in similar treatment with dog dung. Both processes are identical in principle, and bating is commonly used in this country to cover not only these two but also the modern method of using artificial (enzyme) bates.

Bating proper, with hen and pigeon dung, is confined to harness and dressing leather, where a mild softening action is required. The strength of the bate varies considerably with the choice of the tanner, the nature of the materials and the effect desired. It is carried out either in the cold by suspending the hides in the bate liquor for 4 to 8 days, or by paddling and drumming the hides at a temperature of about 35 deg. C. The excreta are usually fermented in water for a week, and strained through rough cloth to remove dirt and sediment before use. This process is now largely superseded by the more hygienic enzyme bates.

Puering with dog dung is still extensively used for certain classes of goods, goat and to a lesser degree sheep. The dog dung is mixed to a paste with water and kept in the dark as much out of contact with air as possible. The paste is diluted with water as required, and is strained before use. The skins remain in the liquor for several hours, at a temperature of 20 to 40 deg. C. according to type of stock, and are occasionally stirred or paddled. The completion of puering can be determined only by the feel of the pelt; it should be soft, flaccid and in a completely fallen condition.

Enzyme Bates

During the course of the last 30 years J. T. Wood has made extensive studies of bating and finally traced the main activity of bate liquors to the presence of enzymes. Since that time various enzyme bates have been put on the market, notably "oropon" and "pancreol," consisting usually of trypsin, together with ammonium chloride and a filler of woody fiber or other suitable material. The latter is supposed to furnish a greater surface for the enzyme, as Wood found that the activity of a puer liquor was greatly diminished by filtration, and increased again on the addition of an inert powdery material.

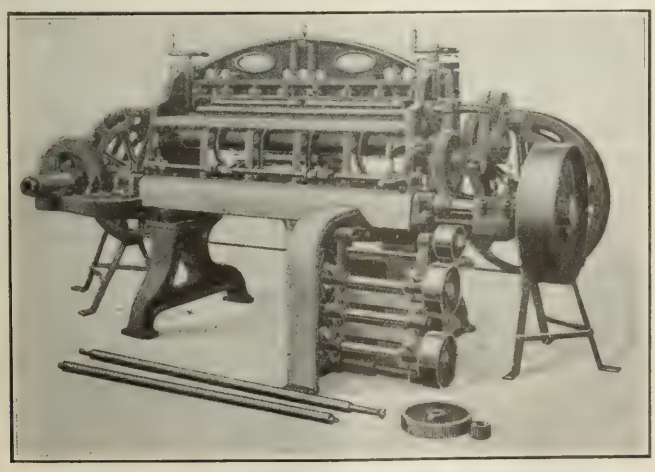

FIG. 14—BELT KNIFE SPLITTING MACHINE

What happens in bating has only recently come to light. It is now known that trypsin hydrolyzes the elastic fibers of the skin, thus loosening the skin structure and removing the binding material of the collagen fiber bundles. This is not all, for skins can be bated without removal of elastin, the finished product being apparently identical in feel and nature. Recent work by J. A. Wilson indicates that commercial bates do *not* digest elastin, while trypsin does; this may be due to absorption of the enzyme by the filler. Probably also the enzyme removes the interfibrillary matter of the skin.

Many patent and secret bates have been put on the market, frequently consisting of various mixtures of fermented or fermentable matter. In general most of these are more of the nature of drenches, but they have met with some application in practice.

Puering is of especial importance in the manufacture of glove leather, to obtain the necessary "stand"—i.e., the skin will not spring back on being stretched. Since the elastic fibers are confined to the grain layer of the skin, it has been suggested that puering may be more effectively carried out by applying a trypsin paste to the grain.

Scudding

Though rarely carried out in this country, the process of scudding usually follows bating in foreign countries. For greasy stock, especially that from animals fed on artificial feeds, it is necessary to remove as much of the skin fats as possible after puering. It is carried out either by hand, over the beam with a blunt knife, or by machine. The machines used are either of the spiral blade type, or, for sheepskins, consist of a number of small, stiff, revolving brushes.

Pickling Prior to Chrome Tanning

Prior to chrome tanning the stock is pickled in a bath of sulphuric acid and salt, followed by a brine bath, just as in the preservation of skins for export by pickling, described in the previous article.

Plumping, Rounding and Splitting

Where hides have been unhaired by enzyme action or by sweating, it is necessary to plump them for purposes where firm leather is required, such as sole. This is accomplished by swelling them in a dilute bath of sulphuric acid.

Hides are frequently rounded prior to tanning—i.e., the offal (bellies and shoulders) is removed, leaving the butt, which may be further divided along the line of the backbone into two bends. The offal, being of less value and looser texture, receives a cheaper tannage.

Hides and skins may be split out of lime or after a preliminary tannage. The split is horizontal, leaving a grain and a "skiver" or flesh. This is usually done on a band knife machine. (Fig. 14.) The knife runs over two pulleys, like an endless belt, and the hide is fed in between two series of rollers, these being adjusted to get the thickness of split desired. Other types of machine, oscillating knife, etc., are also in use. Hide fleshes and

grains are largely used for upholstery, automobile, and bag leathers. Sheepskin skivers are oil tanned for chamois leather, the grains going for hat linings, pocket books, etc.

Legal Notes

BY WELLINGTON GUSTIN

Junghaus Patent for Luminous Compound Invalid

The U. S. Circuit Court of Appeals has affirmed a decree against the American Radium Co. in its infringement suit against the firm of Hipp, Didisheim & Bro., Inc., and others. Plaintiff is assignee of the Junghaus patent, No. 911,401, covering, as it claims, "certain new and useful improvements relating to improved luminous substance for indicators containing radium for the indicating members of clocks, speed gages, and the like." (279 Federal, 1016.)

Passing over the legal technicalities arising in this case, the patent's validity will be considered. The court found that radium paint, or the luminous material here employed, was old. Phosphorescent paints had long been employed on the hands and dials of clocks, but they were not self-luminous. But it was not long after Mme. Curie discovered radium in 1889 that radium paint appeared. The court says it might well be questioned whether it was invention to apply radium paint, instead of phosphorescent paint. But two distinguished students of radium did apply radium paint before Junghaus, and there was put in evidence the Hammer clock and the Kunz watch.

In 1903 Dr. George F. Kunz, the inventor of a radium paint (letters patent No. 789,912), applied radium paint to the hands and dial of his watch, and that watch was in evidence. Major Hammer put radium paint on his clock in 1903, in much the same way as shown in the Junghaus patent. The court said there was a long list of prior art patents and scientific publication on the subject which might invite discussion, but for these two devices.

OBTAINING HIGH ILLUMINATION BY INCREASING BULK OBVIOUS STEP

Plaintiff contended that Hammer did not think of constructing the dial on his clock so that the luminous substance would be imbedded in the figures on the dial, or that the figures would be imbedded in the luminous substance. Much was argued as to the imbedding of the radium paint. It was contended that the problem which Junghaus was called upon to solve was to apply to the hands of a watch a substantial bulk of a luminous compound, consisting of radium and a radio-responsive material, so as to obtain high illumination, and so that the luminous compound will not extend above the hand, and to apply to the hands of a watch this luminous compound, so that it would extend substantially the full length of each hand, and to obtain this illumination near the indicating divisions on the dial, so that the watch might be readily read in the dark as well as in the daytime.

But there was nothing in the claims about "bulk," and the court concluded that no great importance could have been attached to this feature, else it would have appeared in the claims. The patent states simply: "Preferably the substance is present in some considerable bulk where a high illumination is required."

Obviously to apply the substance in considerable bulk did not require knowledge beyond that of one skilled in the art. This the court says was a mere incidental feature which certainly could not be said to have required inventive genius.

Of course, says the court, it is true that many simple devices have exhibited invention, but on the question of invention a patent case in one art is rarely of much help in deciding whether invention exists in another art. Each case is necessarily controlled by its own facts, and in the case at bar there was nothing left for Junghaus to invent.

Further, the court says that while the decisions of foreign courts are not controlling and often not persuasive, because of a different attitude or a different record, it is sometimes comforting to know that other judicial bodies have come to practically the same conclusion as itself, and the fact that the German and Swiss courts, familiar as they must be with the watch industry, have decided adversely to Junghaus is of special interest.

Cargo Owner Not Entitled to Recover on Policy to Ship Owner

In a suit in admiralty brought by the Virginia Carolina Chemical Co. against the Chesapeake Lighterage & Towing Co. and Fireman's Friend Insurance Co. a decree was had in the U. S. District Court against the insurance company and in favor of the chemical company. On an appeal this decree has been reversed and the case remanded with directions to dismiss the suit, by the Circuit Court of Appeals. (279 Fed., 685.)

The suit as against the Chesapeake company proceeded on the theory that it agreed on due consideration to procure insurance for claimant shipper covering a shipment of kainit. It was admitted this company fulfilled its obligation by procuring or maintaining the Fireman's Friend policy. Therefore the suit shifted to one of damages on insurance. But the court held that a contract by a carrier to obtain insurance for the benefit of the cargo owner is not maritime, and a suit for its breach is not within the Admiralty jurisdiction.

Again, it holds that to entitle a cargo owner to maintain a suit on a maritime policy issued to the carrier he must, under the terms of the contract, have become the insured, when the cargo went on board the carrier's vessel.

And a marine policy issued to a ship owner covered any property on which the insured had agreed with the shipper to provide insurance, and also its legal liability where it had not so agreed, but provided it should not cover "where the assured, or any carrier or other bailee, has insurance which would attach if this policy had not been issued." Here the court held that a cargo owner could not recover on such policy for loss of cargo as "the assured," where it had other insurance, nor through liability of the shipowner where the latter was not charged with any fault.

The Graphical Study Of Operating Efficiency

The Description of a System of Graphs Which Were Developed to Analyze Labor Costs, and Which in Addition Reveal Lack of Smoothness in Operating and the Causes for Lost Time

By A. R. Blakey

IN THIS ARTICLE we shall discuss some recent studies in the field of cost accounting and plant development work, rather as an aid to the operating heads and supervisors than as a help to the accounting department. The studies were designed to indicate opportunities for improving costs by bringing some of the salient facts graphically before the operating executive. The following description is therefore given more to explain the time card and graphic representation of plant troubles than as a significant contribution to cost finding.

The industry under consideration was of the continuous process type and the finished products of several plants were quite similar in percentage consumption and size of containers. The problem as originally faced by the company was to determine at various major points the cost of operation and compare the costs of the several plants with the view of establishing, by comparison, friendly competition for lowest costs and bringing to light those methods which produced the best operating results.

Standardizing Nomenclature and Cost Procedure

Naturally the first step was the standardization of cost procedure and nomenclature. Consequently a very detailed flow sheet of all operations was constructed. It showed them in a logical order and included flow lines for transportation and handling into and through the plant. Following this, a very definite set of rules was laid out and a standard nomenclature adopted for all plants in referring to costs. There was a good deal of discussion as to whether the operations should be numbered according to some systematic code. The decision was finally affirmative, because it would much simplify the recording of time in the field to use a number rather than a word description. Therefore the next step was an examination of the flow sheet and the writing in of numbers to cover all operations represented thereon according to some definite system. The rules adopted in assigning code numbers are given in large part in the footnote.[1]

To make the code numbers available, large placards about 3 ft. square carrying both the description of the work and the several code numbers applicable to it were placed in each department or location where such work was carried out.

A Simple Yet Comprehensive Time Card

Now we have nomenclature, how shall we get the true facts coming in and how shall we visualize them? The answer to question No. 1 is Time Cards, and to question No. 2 Plant Graphs, both of which are described herewith. To anyone who has had field experience with the ordinary time card, the idea of having the individual workman fill out a daily card appeals about as much as ice cream for breakfast. It just doesn't work well. Therefore it was perhaps to be predicted that the regular payroll time cards which were distributed at first, showing total hours worked, together with so-called distribution cards one for each code worked under on which to be written name, payroll number, date, occupation number plus hours spent, etc., were doomed to failure. Cards were lost, torn and soiled, and the men hated them naturally. The clerical work was excessive. The difficulties were somewhat intensified by the awkward plant layout, which was not compact and prevented a centralized distribution of cards.

The time card which finally was worked out and proved very successful combined the ordinary payroll card with the distribution information necessary. The card was designed also to minimize clerical effort by the operator. The time spent on a task could be chalked off on the card directly and at the time of the change of assignment rather than waiting until the end of the day and estimating the time spent on the several codes.

With this card we obtained not only the duration of the task but its sequence in the day's work. We obtained the exact time and duration of such and such a shut-down and what its effects were on the following operation, and how the time of its occurrence was related to some necessary or inherent shut-down of operations or to transportation upon which it was depending. In this way we could look up and down the line and see graphically its cause and effect. The card used is shown herewith. It is divided into two main parts, the upper portion acts as the man's payroll card, the lower portion has the clock spread out upon which he chalks off sequence and duration of events for distribution purposes opposite the proper code.

All extensions and arithmetic were done by the office force, and the operator simply chalks off that portion of the clock used in the performance of a given task opposite its code number.

On the reverse side of this card is the "overtime" side, which is quite similar to the straight time side except that it does not repeat name, etc., and the Time Lines begin with 3 instead of 7 o'clock.

How the Executive Gets His Information

So the information was collected on the time consumed in a given task, the ordinary labor charges for the cost accountant. The next step was to portray graphically the workings of the whole plant in one concise picture for the executive and at the same time retain all details of each individual worker. This was accomplished by projecting vertically each individual's time card in its proper place on a "flow sheet" of the

[1]Some of the rules used in assigning the code numbers were as follows:
Use definite groups of numbers for different departments.
All major codes to end in even hundreds as: 100, 200, 300, etc.
All major codes ending in one (1) represent transportation to that operation.
All major codes ending in 2, 3 4, 5, 6, 7 and 8 represent sub-operations at major points.
All major codes ending in 9 represent indirect or non-productive labor, the nature of which may be serialed as 209-2, etc.
All major codes ending in 50 represent repairs, the nature of which to be shown by serial, the serial corresponding to the number painted on machine or part repaired, as 250-5, etc.

GRAPHICAL TIME CARD SHOWING BOTH TIME CLOCK DATA AND DISTRIBUTION TO CODE NUMBERS

plant, allowing one horizontal line for each time card and having the vertical lines representing time lines for the day. The graph given herewith is such a plant picture.

At first sight it might seem rather a laborious task, but the actual construction of the chart was accomplished by a young grammar school graduate during the forenoon, during which time he also completed the distribution of the payroll.

In further explanation of this plant graph and method of plotting, let us consider the Dynamite Mixing House. Here we find there were three men engaged in mixing dynamite from 7 o'clock a.m. until noon without any interruptions. After lunch there were no empty hods for conveying the mixed powder to the packing machines, so the house was idle and the two truckers were there waiting for a delivery until 1:30 p.m. The house then produced until 2 p.m., when they began to clean up, spending one hour and a half at this, during which time the truckers also helped. From 2 to 3 you will note two of the men left the operation and assisted in cutting slugs in Dynamite Box Pack No. 114 and returned at 3 o'clock to their original station and helped in cleaning up.

In Dynamite Box Pack No. 312 you will note there were seven men working without any hold-up except lunch and the clean-up at end of day. From this it is seen that for each man in the house there is a distribution line, and laid off on this line are the intervals as shown on the distribution half of his time card. In making a composite plot of a house these man lines are built one on top of the other corresponding in number to the number of men. The truckers who delivered from building to building appear on the graph only when actually in the house helping the operator with his work.

The time card shown represents the work done by one of the men in Dynamite Mix House No. 310.

In studying these graphs from day to day, the tendencies of the plant are clearly visualized.

The idle intervals showing up in the Gelatin Cartridge are caused by the fact that the Mixing House just

ahead is under capacity for the cartridge machine. When the reserve Mixing House is thrown in and the cartridge machine kept at capacity, then we have idle intervals in the Mixing House, showing that this section of the line has a poor capacity balance.

Extension of the System Possible

The above system is quite flexible and can be made as detailed or as simple as desired. Instead of having each individual worker make out his distribution, the foreman can make it out for the whole house as the day progresses, where there are not many workers—exactly as each house is here represented. The usual method is for the foreman to write up his house report at the end of the day, giving production figures, time of shutdowns, man-hours, etc., but it is largely guesswork except the production figures; besides, the present house reports are usually such that they do not lend themselves to a continuous record of the events of the day.

If the lower half of each house report had the "time lines" laid off on it so the exact time and duration of these events could be chalked up for each house as they occur, a much more intelligent study with very little work could be made of the average plant which does not care to go into much detail. These house reports could then be assembled quite similarly to the graph shown and the salient points of operation could be quickly noted.

Kenvil, N. J.

The Hygroscopicity of Tetryl and Tetranitraniline

By L. Grier Marsh
Assistant Explosive Chemist, Pittsburgh Station, U. S. Bureau of Mines

THIS WORK is for the main part a continuation of the study of the hygroscopic properties of organic explosives, which on the suggestion of Dr. Charles E. Munroe, chairman of the committee on explosives investigations of the National Research Council, was begun by Huff in his determination of the hygroscopicity of TNT[1] and continued by the author in a previous work on the hygroscopicity of picric acid.[2] The procedure followed in all cases is essentially the same and involves a study of the hygroscopicity from the calculated vapor pressures of saturated aqueous solutions of the substances investigated, and also experimentally determined data on the amount of moisture taken up by each compound by methods previously outlined in detail and briefly summarized below.

The hygroscopicity of TNA has been given by Flurscheim[3] as 0.12 per cent for a material made on a laboratory scale and exposed in an atmosphere of 85 per cent humidity for a week. The uncrystallized material was found to absorb under the same conditions about 0.023 per cent. Constant weight with 0.13 moisture was obtained on a sample of (green) commercial material that had been completely dried in the laboratory at 95 deg. C. A more finely divided yellow TNA became constant after 32 days with 0.19 per cent moisture.[4] The solubility of TNA in water was given as one part in 50,000 at 13 deg. C.

Comparatively little work has been published on the properties of tetryl. Flurscheim states that pure tetryl takes on about 0.30 per cent of moisture at constant weight determined under the same conditions as TNA and that the uncrystallized material attains constant weight with an increase of about 0.024 per cent. Taylor and Rinkenbach, in the Bureau of Mines Explosives Chemical Laboratory, are at present investigating the solubility of tetryl and TNA, and they find the solubility of the pure tetryl in water at 32 deg. to be 0.0088 gram per 100 grams of water. The TNA used had a solubility of 0.0175 part per 100 grams of water.

Calculated Hygroscopicity

Assuming the existence of a close relationship between the hygroscopicity of compounds not forming crystalline hydrates and the vapor pressures of their saturated aqueous solutions and the applicability of Raoult's law to the compounds in question, for the purpose of comparison, the vapor pressure of a saturated aqueous solution of tetryl at 32 deg. can be calculated and a measurement of its hygroscopicity correspondingly determined. From Raoult's law

$$\frac{P_1 - P_2}{P_1} = \frac{n}{N + n}$$

where the solubility of tetryl in water at 32 deg. is taken as 0.0088 per cent and the vapor tension of water at the same temperature as 35.372 mm. of mercury,[5] the vapor pressure of a saturated aqueous solution of tetryl in water at 32 deg. is found to be 35.3718 mm. of mercury, or 99.9994 per cent of that of pure water. The TNA solution had a vapor pressure of 35.3716 mm. of mercury, which is 99.9988 per cent of that of pure water.

TABLE I—VAPOR PRESSURES OF SATURATED SOLUTIONS

	Vapor Pressure of Saturated Aqueous Solutions, Mm. of Mercury	Ratio to Vapor Tension of Pure Water, Per Cent
Picric acid	35.3265	99.872
TNT	35.371427	99.9983
Tetryl	35.371804	99.9994
TNA	35.371591	99.9988

The difference in vapor pressures is so slight that either compound can be only slightly hygroscopic. A comparison between the vapor pressures of saturated aqueous solutions of the different compounds at 32 deg. C. is shown in Table I.

Materials

The experimental work was carried out on both the pure tetryl and TNA and also on two commercial grades of each material containing the ordinary impurities characteristic of each compound.

The purified tetryl was prepared by the following method: Commercial material was dissolved in hot benzene, the solution filtered and permitted to cool. The mother liquid was then decanted and the crystals permitted to air dry. The dried tetryl was then dissolved in hot alcohol, the solution cooled and filtered, the tetryl redissolved in hot alcohol and thrown out of solution by the addition of an equal volume of cold water. The product thus obtained was filtered off, washed once with cold water, twice with cold alcohol, and permitted to dry in a sulphuric acid desiccator for a week.

The pure TNA was prepared by dissolving commer-

cial TNA in hot glacial acetic acid, filtering the solution, crystallizing in the cold, washing the product three times with cold glacial acetic acid and drying in an oven at a temperature from 45 to 50 deg. C. for three days.

The analyses of the different materials are given in Tables II and III.

The determination of the insoluble matter in TNA was made by the use of hot benzene as a solvent, while acetone was used for tetryl.

Experimental

The method used was that designed by Taylor and Cope and given in detail in a previous paper.[6] The essential features of this method involve the determination of the increase in weight of two gram samples of each material after intervals of 5, 17, 24, 41, 48 and 72 hours, where the material is exposed in open porcelain crucibles over water in sealed quart jars, and the jars submerged under water in a large thermostat at a temperature of 32 deg. C. automatically controlled, within a range of 0.10 deg. C. Blank tests on empty crucibles were run in conjunction with the regular tests.

These blanks are necessary especially with materials of low hygroscopicity, as there is a small gain in weight due to the deposition of a film of moisture.[7] This condensation is due to the slight fluctuations in temperature.

The results obtained are shown in Table IV.

Conclusions

The results obtained show that both pure tetryl and TNA are non-hygroscopic and that the ordinary commercial products are slightly hygroscopic, due to the impurities present.

Wood Distillation in 1921

Reports made to the Bureau of the Census show a decrease in the activities of the establishments engaged primarily in wood distillation during 1921, as compared with 1919. The total value of products reported amounted to $9,258,500 in 1921, and to $32,545,300 in 1919, a decrease of 71.6 per cent.

Of the 90 establishments reporting products valued at $5,000 or more for 1921, 35 were located in Pennsylvania, 17 in New York, 12 in Michigan, 4 in Louisiana, 3 each in Alabama, Florida, Georgia, New Jersey and Wisconsin, 2 each in Mississippi and North Carolina, and 1 each in Kentucky, Tennessee and West Virginia. Of the active establishments in 1919, 20 were idle in 1921.

The decrease in production has been accompanied by decreases in number of persons employed, in the total amount paid during the year in salaries and wages, and in the cost of materials.

The returns indicate that the combined output of all establishments was approximately 34 per cent of the maximum capacity, based upon a demand requiring full running time; 44 establishments with 36 per cent of the products being above the said average, and 46 with 64 per cent below.

Detailed statistics of products of the wood-distillation industry for the years 1921 and 1919 are given in the following table:

	1921	1919	Per Cent of Decrease
Products—total value	$9,258,500	*$32,625,300	71.6
Wood alcohol:			
Crude, gal.	5,684,500	9,104,000	37.6
Gal.	5,009,300	6,980,700	28.2
Value	$2,307,500	$5,593,500	58.7
Average unit value, gal.	$0.46	$0.80	....
Made and consumed, gal.	675,200	2,123,300	68.2
Refined, gal.	1,111,700	7,391,000	85.0
Gal.	995,300	6,984,700	85.8
Value	$727,500	$8,381,900	91.3
Average unit value, gal.	$0.73	$1.20	....
Made and consumed, gal.	116,400	406,300	71.4
Acetate of lime, lb.	57,927,000	168,956,000	65.7
Lb.	53,563,000	153,910,000	65.2
Value	$736,100	$2,682,200	72.6
Made and consumed, lb.	4,364,000	15,046,000	71.0
Chemicals, in order named as to value: Acetic acid, formaldehyde, methyl acetone, acetone, and acetone oil	$411,000	$2,023,300	79.7
Turpentine (from wood):			
Gal.	441,800	1,534,300	71.2
Value	$233,200	$1,207,700	80.7
Rosin (from wood):			
Bbl. (280 lb.)	52,400	234,000	77.6
Value	$199,400	$2,742,500	92.7
Charcoal†:			
Bushels	19,990,000	48,056,000	58.4
Value	$4,049,500	$8,221,400	50.7
Other wood products and derivatives‡	$588,700	$1,220,200	51.8
All other products	$5,600	$552,600	98.1

* Includes byproducts from other industries to the amount of $79,991.

† Does not include products of the charcoal (other than wood distillation) industry to the value of $447,234 for 1921; and $589,418 for 1919.

‡ Includes for 1921: Tar, 1,569,186 gal., $185,450; tar oils, 400,414 gal., $92,400; wood creosote, 92,916 lb. $15,100, and miscellaneous wood products, $295,750.

The Production of Nitrogen and Hydrogen for Synthetic Ammonia Manufacture*

By Hugh S. Taylor
Professor of Physical Chemistry, Princeton University

The Production of Nitrogen and Hydrogen for Synthetic Ammonia Represents at Least 75 Per Cent of the Cost of Production of Ammonia and Yet It Has Had but Little Attention in the Literature—The Efficiencies of Various Methods of Production and Their Future Developments

THE production of 1 ton (2,000 lb.) of fixed nitrogen, as ammonia, involves the theoretical consumption of approximately 430 lb., or more than 82,000 cu.ft., of hydrogen, measured at ordinary temperatures and pressures. One-third of this volume of nitrogen is also required, which may be in part produced simultaneously with the hydrogen or may be wholly supplied from a nitrogen-producing plant. The German synthetic ammonia plants in 1918 had a capacity of 650 metric tons per day. The process is now operated on a technical scale in the United States (at Syracuse, N. Y.) and is being developed in France, England and Norway. The importance of this division of gas technology is, therefore, readily grasped.

The gas mixture is required for the synthetic operation in a high state of purity. Inert gases, such as the argon group and methane, act as diluents and, in a circulatory system, necessitate a periodical blowing-off and loss of gas in order that the inert constituents do not accumulate beyond a working maximum. Water vapor, oxygen, carbon dioxide and carbon monoxide are catalyst poisons which when present continuously in concentrations of 0.01 to 0.1 per cent lower the efficiency of the synthesis quite markedly. Hydrogen sulphide and sulphur compounds are permanent catalyst poisons, cumulative in effect and eventually necessitating, if permitted to intrude, a renewal of the ammonia-making catalyst.

As a result of the large volume requirements of gas and the high purity essential to successful synthesis, the problem of preparation of the gas mixture is the most important in the cycle of operations from elementary nitrogen to fixed nitrogen product, whether this be ammonia, nitric acid, oxides of nitrogen, ammonium sulphate or other fertilizer compound. It has been computed[1] that the preparation of the compressed nitrogen-hydrogen mixture involves as much as 75 per cent of the total cost of the ammonia produced. The attention which has been paid in past discussions to the actual synthetic operation as compared to the gas preparation is out of all proportion to its relative importance and cost in the cycle of reactions. Recent literature abounds in discussion and reports of the ammonia-making processes. Scant attention has been paid to hydrogen and nitrogen technology.

A Review of Existing and Possible Processes

The Liquefaction Process

The earliest synthetic ammonia plant, the Badische Co., at Oppau, operated on hydrogen obtained from water gas at 20 atmospheres pressure by liquefaction of the carbon monoxide in a liquefaction system of the Linde type, diagrammatically shown in Fig. 1. The nitrogen was obtained by fractionation of the liquid air, *h*, *i*, boiling under a partial vacuum, used to establish the low temperature (—205 deg. C.) necessary for the separation of the carbon monoxide from the hydrogen. The carbon monoxide was employed, after being vaporized, to drive a gas engine and thus produce the power requisite for compression of the water gas and of the air employed in the liquid air cooling system. Also the power requirements for a pressure water scrubber to remove carbon dioxide and an ammonia refrigeration system to remove water vapor were supplied from the same source.

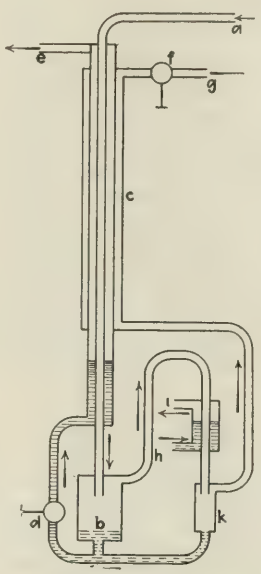

FIG. 1
LINDE LIQUEFACTION SYSTEM FOR HYDROGEN PURIFICATION

The normal purity of the hydrogen obtained corresponds closely to a gas of the following composition: $H_2 = 97$ to 97.5; $CO = 2$ to 1.7; $N_2 = 1$ to 0.85 per cent. Approximately 40 per cent by volume of the original water gas is received in this form from the liquefaction system. This gas, before use in ammonia synthesis, must be freed from the residual carbon monoxide, this being achieved of late by the Badische Co. by solution in ammoniacal cuprous formate under a pressure of 200 atmospheres. In the earlier stages of the process the carbon monoxide was absorbed at 200 atmospheres in hot caustic soda solution with the formation of alkali formates. Thus purified, the hydrogen residue contains less than 0.1 per cent carbon monoxide and admixed with the theoretical ratio of nitrogen from the liquefaction system was so used in the synthetic operation.

The Water Gas Catalytic Process

The liquefaction process was discarded at Oppau in favor of the water gas catalytic process. In essentials this process consists of the oxidation at 500 deg. C. of the carbon monoxide in water gas by steam in the presence of a catalyst (oxide of iron), the reaction occurring being representable by the equation

$$H_2 + CO + H_2O = 2H_2 + CO_2$$
Water gas

The reaction is an equilibrium process and the final composition of the gas is dependent on the steam-water gas ratio, the temperature of operation and the efficiency of the catalyst. Furthermore, by using water gas admixed with semi-water gas (a gas containing the

*Paper read before the American Institute of Chemical Engineers, Buffalo, N. Y., June, 1922.

[1]Nitrogen Products Committee Report, British Munitions Inventions Department.

products of both air-blow and steam-run in the water gas process) a product may be obtained containing the bulk of the nitrogen required in the subsequent synthesis requiring only small amounts of nitrogen from the liquefaction of air for purposes of exact ratio adjustment. Details of plant, materials, engineering and operation of this process have already been discussed before this society[2], so it is not necessary to recapitulate such in this article. Fig. 2 shows the process diagrammatically. Emphasis only need be laid on the factor which accounted for the change from the liquefaction process to the catalytic process. The factor involved is the water gas: hydrogen ratio or, in other words, the ratio of fuel consumption to hydrogen yield in the two processes. Whereas somewhat less than 40 per cent by volume of the original water gas is received as hydrogen in the liquefaction process, the yield in the catalytic process, as can readily be seen from the previous equation, is equal theoretically to that of the water gas consumed. In actual practice it is possible to receive unit volume of hydrogen by the expenditure of 1.25 volumes of water gas. The fuel bill, therefore, should be just one-half that obtaining in the liquefaction process. The purity of the product corresponds approximately with that from the liquefaction process, so that no advantages accrue to the catalytic process in that respect.

The Steam-Iron Process

The industry of oil hydrogenation for the production of soap stock and of edible fats has made but little use of hydrogen from either of these two sources. This should, in the main, be attributed to the nitrogen and carbon monoxide present in the hydrogen so obtained. In ammonia synthesis nitrogen is a reactant; in oil hardening it is a troublesome inert, present to the extent of several per cent, depending on the nitrogen content of the original water gas. Until recently the methods technically developed for the removal of 2 to 4 per cent carbon monoxide have been operated at 100 atmospheres pressure or upward, generally at the working pressure of the ammonia synthesis operation. Such pressures are entirely unnecessary in technical hydrogenation and therefore involve unnecessary compression costs.

Operation of the carbon monoxide purification processes at lower pressures is less satisfactory. Hence the additional objections to these two processes of hydrogen manufacture for hydrogenation work. The chemical method of hydrogen production for the oil-hardening industry has therefore been what is variously known as the steam-iron process or the iron-contact process. It consists in the production of hydrogen by the interaction of steam and iron at temperatures in the neighborhood of 700 deg. C. The contact mass is regenerated by reduction of the iron oxide in a stream of a suitable reducing gas, normally water gas, whereupon the cycle of operations may be repeated. The hydrogen thus produced is easily obtained in a high state of purity. The gas can leave the producing system containing less than 1 per cent impurity, of which the bulk is carbon dioxide, easily removable, with but small fractions of 1 per cent of carbon monoxide and nitrogen. With special precautions these impurities can be diminished still further, even in the production process. As will be shown, also, newer methods of purification are capable of easy and cheap removal of carbon monoxide not in excess of 1 per cent, even in the presence of several per cent of carbon dioxide. The steam-iron process, therefore, without special refinement, is capable of yielding hydrogen of a purity sufficient for ammonia synthesis purposes.

The non-utilization of the steam-iron process in nitrogen fixation work is to be attributed to three main factors, (*a*) the fuel cost, (*b*) the intermittency of the process and consequent high operating cost and (*c*) the high cost of plant and of renewal of plant. These factors merit detailed consideration.

The fuel cost is high, since in the best practice hitherto attained in this process at least 2.5 volumes of water gas have been normally consumed in the production of 1 volume of hydrogen. The process at present, as regards fuel cost, ranks on a parity with the liquefaction process and is considerably inferior to the catalytic process. I have attempted elsewhere[3] to show that the high ratio of water gas consumed to hydrogen produced was to be attributed to the equilibrium relationships in the essential reactions of the process in both steaming and reducing phases. These reactions may be formulated by means of the following reversible equations:

$$3Fe + 3H_2O = 3FeO + 3H_2$$
$$3FeO + H_2O = Fe_3O_4 + H_2$$
$$3Fe + 3CO_2 = 3FeO + 3CO$$
$$3FeO + CO_2 = Fe_3O_4 + CO$$

Accepting the most recent and reliable data obtained by a single investigator covering these several equilibria[4], I have computed the following tables of hydrogen and carbon monoxide consumption at equilibrium and the consequent water gas: hydrogen ratio deduced upon the assumption of such equilibrium conditions in the reducing phase.

Fe_3O_4-FeO Reaction

Temperature	Per Cent H_2 Consumed	Per Cent CO Consumed	Water Gas:H_2
570	27	47	2.7
650	41	55	2.1
750	58	67.5	1.6
850	75	75	1.33

FeO-Fe Reaction

Temperature	Per Cent H_2 Consumed	Per Cent CO Consumed	Water Gas:H_2
570	27	47	2.70
650	30	44	2.70
750	35	40	2.66
850	38	36	2.70

From these figures it is evident that, assuming equilibrium, only by operating at high temperatures and on the Fe_3O_4-FeO cycle alone, a ratio of water gas consumed to hydrogen produced equal to that yielded by the water gas catalytic process would be attained. The disadvantage of working on the Fe_3O_4-FeO cycle is made apparent by referring to the preceding equations, whence it is clear that only one-quarter of the output per unit of contact mass is obtained as compared with that yielded by the complete Fe_3O_4-Fe cycle.

Peculiar Conditions at the Start of Steaming and Reducing Periods

Recent investigations by Richardson, Vibrans and Bell[5] on actual plant operations as well as in laboratory trials have shown that in the first minutes of either the reducing phase or alternatively of the steaming period the conversion of the reacting gases is greater than that calculable from the above equilibrium figures or from

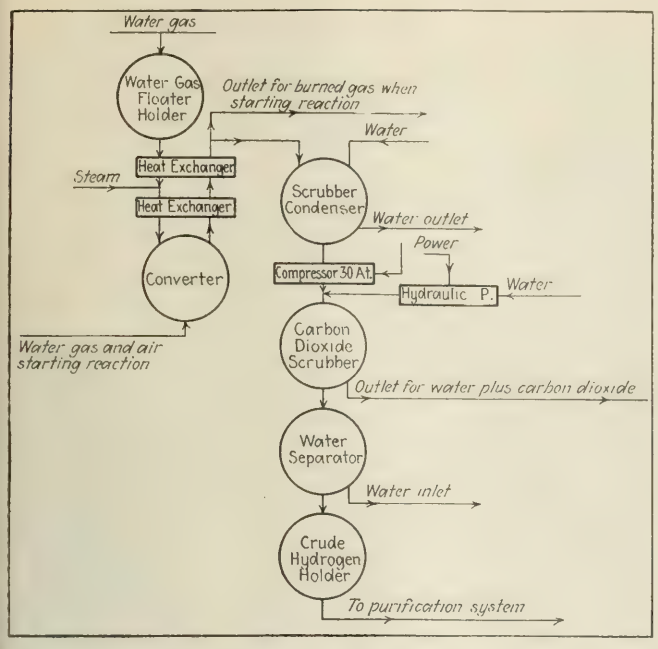

FIG. 2—FLOW SHEET OF THE WATER GAS-CATALYTIC PROCESS

any such data to which a degree of reliability can be assigned. It was found that the oxidation of the water gas to carbon dioxide and steam was much more nearly quantitative than the equilibrium figures would suggest. The implication of these results is that under conditions such as prevail in the first moments of the respective reactions it should be possible to obtain almost unit volume of hydrogen by the expenditure of a unit volume of water gas. For every molecule of water gas oxidized in the reducing phase a molecule of hydrogen accrues in the steaming phase. With such a water gas: hydrogen ratio, the steam-iron process is immediately on a parity with the catalytic process as regards fuel consumption. In addition, the gas purity and ease of purification of such hydrogen give to it a measure of importance worthy of serious consideration.

The explanation of the divergence between experimental results and theoretical equilibrium data is deserving of attention. At the moment, I incline to the view that complete consumption of the hydrogen and carbon monoxide of the water gas is approached in the early moments of the run, because in those moments the experimental conditions are such that the criteria for equilibria are not fulfilled. In any of the reactions involved as, for example,

$$Fe_3O_4 + CO = 3FeO + CO_2$$

it may readily be shown that, for a definite equilibrium ratio between the two gases, it is demanded by the phase rule that *two* solid phases shall be present. At the outset of a run this condition is apparently not fulfilled; the gas in its travel through the retort system is then continually in contact with only one solid phase. At the beginning of the reducing phase this is the ferrous-ferric oxide Fe_3O_4. Only when the two solid phases Fe_2O_3 and FeO are present should the equilibrium be established. With only Fe_3O_4 present, oxidation of the carbon monoxide continues until either the carbon monoxide is completely converted to the dioxide or reduction of the ore is carried to the stage throughout the contact mass at which equilibrium relationships are possible.

The direction which development work in the steam-iron process should take is, therefore, obvious. Work should be directed toward devising working conditions such that the circumstances prevailing in the earlier moments of the process as at present conducted could be continuously maintained. The reorganization of the steam-iron process which such a study would involve would undoubtedly bring with it many improvements in the chemical engineering aspects of this industrial process, which hitherto has been left far too much in the hands of the empiricist, without attention from scientifically trained men. Diagrams of the multiple and single retort units as now operated are shown in Figures 3 and 4 respectively. In such a reorganization, the intermittency of the process, which is quite unnecessary, could be eliminated. Operating costs should thereby be lowered. Cost of plant and of plant renewal would also receive attention. It is not too much to hope that the steam-iron process technologist would profit, in respect to plant and plant renewal, by the experiences of others in the matter of heat-resisting alloys and the economies resulting from their substitution for cast iron.

Given a steam-iron process so modified as to give a fuel:hydrogen ratio comparable with that now attainable in the water gas catalytic process, the advantages would all be with the steam-iron process. The expensive

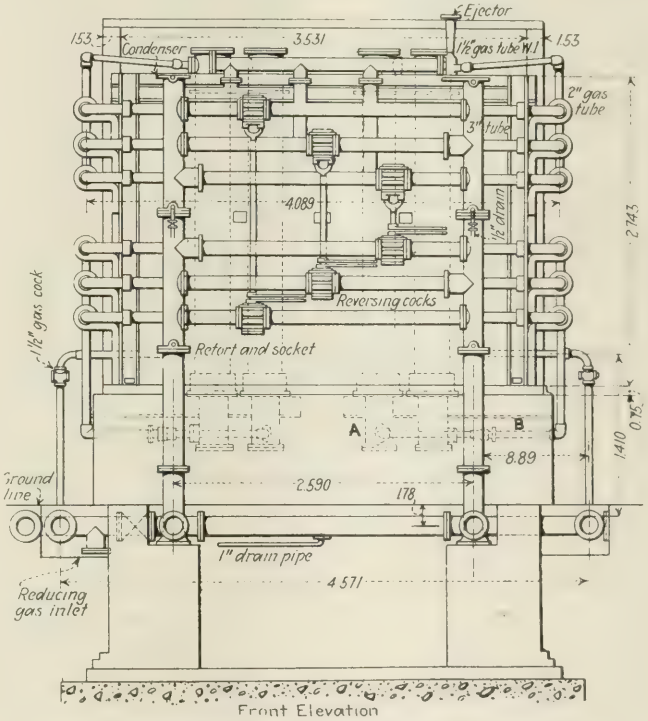

FIG. 3—MULTIPLE UNIT RETORT FOR STEAM-IRON PROCESS FOR HYDROGEN (From *Engineering*)

items in the water gas catalytic process are the purification processes. The removal of upward of 30 per cent carbon dioxide and a residual 2 to 4 per cent carbon monoxide is attained only at an expense somewhat greater than that involved in the production of the hydrogen-rich gas containing these impurities. Steam-iron process hydrogen, on the other hand, contains but 2 to 4 per cent total impurities, of which 1 to 2 per cent is carbon dioxide, 0.1 to 0.5 per cent carbon monoxide and residual sulphur compounds and nitrogen. The Harger-Terry process[6] of preferential combustion of carbon monoxide in hydrogen has solved the problem of purification of steam-iron process hydrogen satisfac-

[6]Brit. Pat. 127,609 (1917); U. S. Pat. 1,366,176.

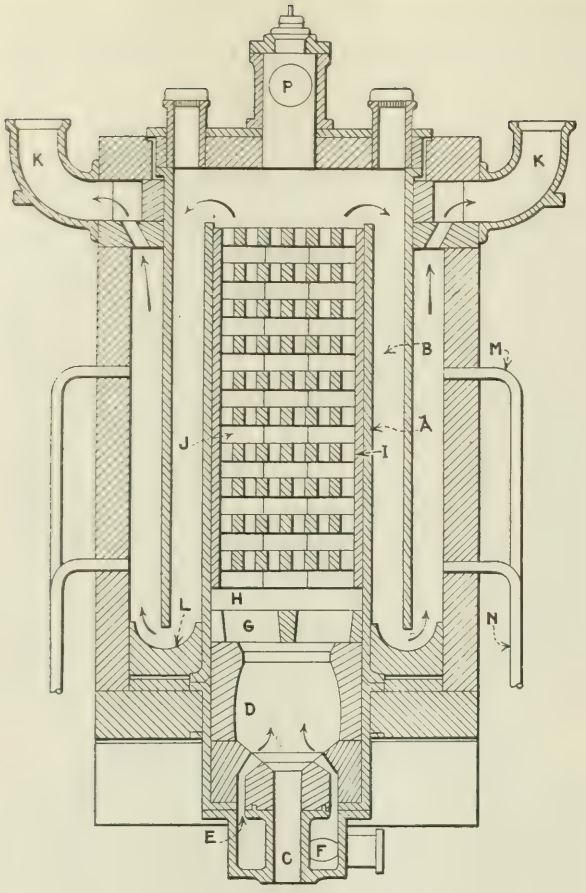

FIG. 4—SINGLE UNIT RETORT FOR STEAM-IRON PROCESS FOR HYDROGEN

torily and cheaply. It has now been operated successfully on a large technical scale in the United States. The process as now operated is applied to the gas leaving the iron oxide box system used to remove hydrogen sulphide from the gas issuing from the retorts. The sulphur-free gas so obtained is admixed with a small percentage of steam and oxygen sufficient to burn twice the theoretical quantity of carbon monoxide present. The mixture is raised to 200 deg. C. by a heat exchanger system and passed over a modified iron oxide catalyst containing suitable promoters at a temperature within the interval 200 to 250 deg. C. In actual practice, on a technical scale a gas containing 0.5 per cent carbon monoxide has been purified so that less than 0.03 per cent of this impurity is left after the passage of the gas through the catalyst system. The carbon dioxide so produced, together with that originally present in the gases leaving the steam-iron process retorts, may be removed in the normal manner. In American practice this usually consists in scrubbing with caustic soda solution in coke-filled towers. In England lime boxes have been mainly used. The gases leaving such a purification system are practically exclusively hydrogen, the impurities, with the exception of nitrogen (which also can, if desired, be kept quite low in concentration), never exceeding in such case more than a small fraction of 0.01 per cent. The product is therefore eminently suitable for ammonia synthesis purposes. A contrast of the purification process involved, carried out wholly at atmospheric pressure, at slight cost, with simple apparatus, with that involved with water gas catalytic process hydrogen, at once establishes its worth. Therefore, the steam-iron process still deserves the most thorough attention of the hydrogen technologist.

Electrolytic Hydrogen

At sources of cheap electrical power the electrolytic method of generating the gas will always be primarily considered. It is for this reason that in developments of ammonia synthesis in Norway electrolytic hydrogen is contemplated. This hydrogen is so pure that many of the problems of ammonia catalysis, bound up with the impurities in chemically prepared hydrogen, disappear. In such places as Norway, power costs are relatively less important. Plant cost, however, represents still quite an item in the economy of the hydrogen production. In America, even the electrical energy from water power is more costly than in Norway. Hence in America, even with water power, and more so with steam power, the electrolytic hydrogen industry for ammonia synthesis must meet competition from other types of hydrogen in both power costs and plant costs.

The electrolytic hydrogen problem must be considered as a hydrogen problem, as estimates of hydrogen costs based upon assumptions of a market for byproduct oxygen will be fictitious. The byproduct oxygen resulting from electrolytic production of the hydrogen will far exceed the extreme *present* oxygen-consuming capacity of any reasonable radius of industrial territory. It is necessary therefore to assume the oxygen wasted to the atmosphere.

The interdependence and variability of power charge, output and capital cost of an electrolytic plant make a complete analysis of the problem diffcult. An excellent effort in this direction has recently been made by Allan[7] based upon the use of off-peak power and of cells with higher than usual amperage. Allan predicates that in many hydro-electric plants off-peak power "could be sold for as low as one mill per kilowatt-hour and probably would not exceed 2.5 mills per kilowatt-hour under the most unfavorable conditions." For successful competition in ammonia synthesis the power costs must be within the above maximum.

The tendency toward high-amperage cells for higher operating efficiency at lower costs as indicated by Allan will certainly be followed in successful efforts to produce hydrogen for ammonia synthesis by the electrolytic method. Indeed it may be stated that the figure quoted by Allan of 1,350 amperes as the normal current capacity of his cell will probably be greatly exceeded. During the war period experiments in the building of 10,000-ampere units were successfully engineered. It was found that a unit of such size could be operated with a voltage drop of 2.5 volts. With an overload, giving a cell operating at 15,000 amperes, a potential of 3 volts per unit was required. Wide flexibility of operating range with minimum variation in working efficiency will constitute an important factor in the design of such cells. It has been stated that the initial cost of such high amperage cells is not at all proportionate to that of the number of 500- to 1,000-ampere cells required to yield the same gas output. Hence a proportionate diminution in initial cost and therefore in interest, depreciation, wear and tear should result. Initiation of electrolytic manufacture of hydrogen for ammonia synthesis will constitute a bold experiment—if successful it will lead to industrial developments far outside the range of ammonia synthesis alone, by reason of the simultaneous oxygen production, uses for which would inevitably be sought.

The Problem of Carboy Closure

Review of the Manufacturing Chemists' Association Report on the Use of Neck Grinding Machines for Carboy Closure

AS PART of a comprehensive program of study in connection with the difficult problem of carboy closure, a sub-committee of the Manufacturing Chemists' Association of the United States has submitted a report entitled "Carboy Neck Grinding Machines and Their Application to Carboy Closure."

In their preliminary study they found it extremely difficult to provide an efficient and suitable closure for carboys with chipped or cracked necks. Many materials have been used to seal the closure, such as plaster of paris, Pecora cement and many special mixtures, but all were found to be unsatisfactory in some respects. It therefore became necessary to eliminate if possible the cracked or chipped necks in carboys. During a general discussion of the subject it was suggested that it might be possible to grind down the necks that were chipped or cracked. Mr. Gayner, of the Gayner Glass Works, said that such a machine was in use in his works, but that it was scarcely sufficiently developed for ordinary use. He nevertheless offered the use of his ideas and experience.

Experimental Work by Merrimac Chemical Co.

Mr. Callahan, of the Merrimac Chemical Co., a member of the sub-committee, undertook an investigation of the proposal. He constructed preliminary machines and after the expenditure of considerable time and money brought the machine to a point of efficiency where it can be considered commercially practicable. A side elevation of the machine finally developed at the Merrimac Chemical Co. is shown in Fig. 1. This diagram reveals the essential principle—that of supporting the carboys on a horizontal carriage and bringing them in contact with rotating cast-iron disks. Two carboys may be ground at the same time by an unskilled laborer and it is reported that the power consumed is relatively small.

Grinding off the chipped neck gives a smooth surface on which to seat a gasket and should eliminate leakages that have been due to chipped or cracked necks. There is a distinct saving in the expense of effecting good closure, because the quantity of plaster of paris is very much diminished. A cleaner and better closure is also obtained.

Machine Eliminates Buyer-Seller Disputes

A factor not to be neglected in connection with the use of this machine is the elimination of all controversy as to the chipping or breaking of the necks of carboys. Frequently a distinctly unpleasant controversy is the result of shipping out carboys with chipped necks. Consumers often claim full credit for returning carboys in good condition when the necks are chipped and the producer is very frequently hard put to know whether he had chipped the carboy necks or whether the consumer actually was responsible. This leads to compromises which are not satisfactory to either side. Under the new régime, if necks were all sent out smooth, then any return carboys which are chipped must be due to improper treatment by the customer or the transportation company.

Several other points about the operation of the machine are worthy of note. In the first place, the carriage on which the carboy rests is given a cross-motion so that the wear is comparatively even over the surface of the grinding disk. In addition the longitudinal movement of the carriage is automatic, which greatly facilitates operating. Finally, the actual grinding is done with a cast-iron disk which is fed with a mixture of sand, emery and water directed on to the disk at the point of contact with the carboy. It is also distinctly worth noting that the machine will grind down the neck of a carboy at the average rate of half an inch in 5 minutes and at an average cost of less than 10 cents per carboy.

Formal Recommendations of the Committee

The following series of recommendations were adopted by the committee and submitted as a preliminary to the more complete report on carboy closure:

1. That glass carboys used for the shipment of corrosive liquids must have an even surface around the

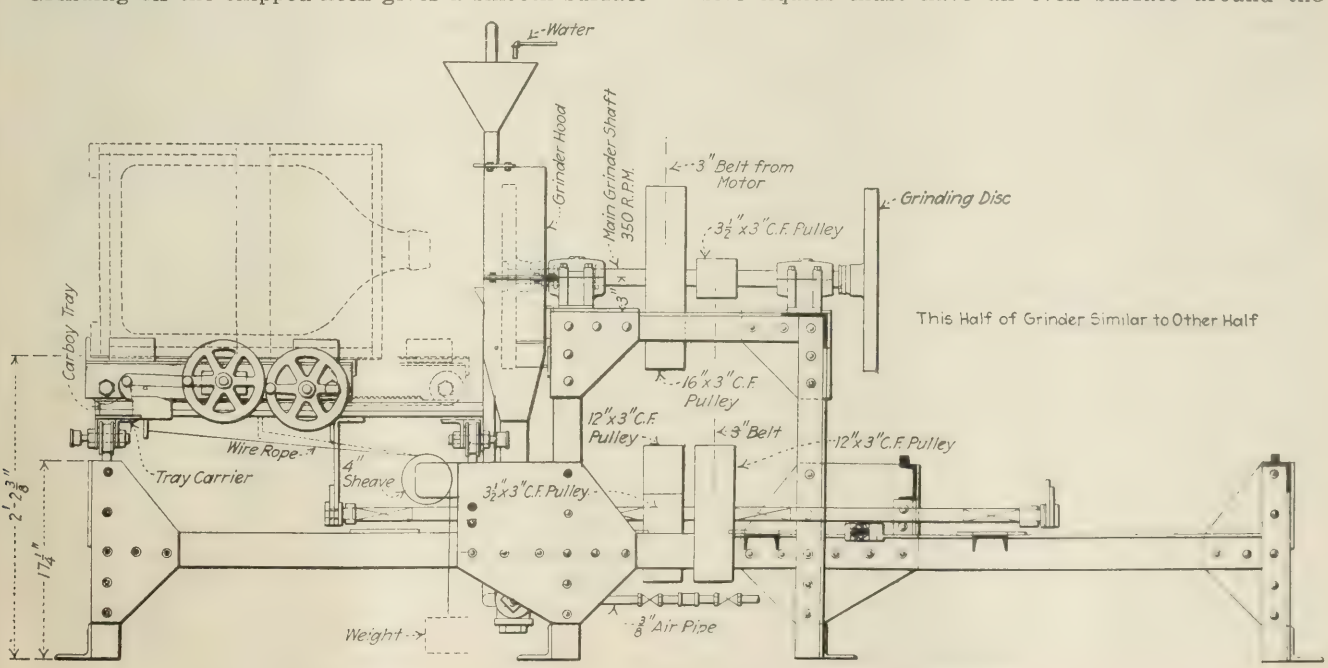

FIG. 1—SIDE ELEVATION OF CARBOY NECK GRINDING MACHINE

mouth on which to seat the gasket; this surface must be at least $\frac{1}{4}$ inch in width for carboys of 7 to 13 gal. capacity and at least $\frac{3}{16}$ inch in width for carboys of less than 7 gal. capacity.

2. That immediate action be taken to advise all users of carboys as to the undesirability of using carboys with chipped and cracked necks, pointing out the practicability of reconditioning such carboys and supplying them with blueprints of the carboy neck grinding machine as developed up to the present time.

3. That the Bureau of Explosives be requested to take appropriate action at some future date such that all concerned will have ample opportunity to prepare themselves for the change, to make the provisions of recommendation 1 obligatory and effective throughout the United States and Canada.

To anyone who has dealt with the problem of carboy closure, this report will appeal as being statesmanlike and progressive. The Manufacturing Chemists' Association is to be commended for furthering such work.

Defects in Baked Enamels

Peculiar Lines on the Otherwise Bright Surface Prove to Be Scratches Caused by a Brass Nozzle—Eliminated by Using an Iron Nozzle

By G. W. Walker
Hupp Motor Car Corporation

CERTAIN peculiar defects having appeared in enameled automobile fenders, an investigation was made to determine, if possible, the cause of these defects. Not all the fenders in the same lot showed the defects—which consisted of lines, some long, others short, in the otherwise bright and uniform surface of the enamel. Along these lines the enamel was "dead"—that is, without luster—and had an appearance as if a thread had been drawn over the wet enamel. These defects appeared through two coats of enamel when baked on.

When the enamel was carefully removed from such lines by use of a solvent, no defect could be found in the metal beneath even on magnification. It was suggested that the metal was "porous," but photomicrographs failed to reveal any pores.

It was noted that these defects generally appeared on certain parts of the fenders and more generally near the crown.

On following through the various operations preparatory to enameling, it was found that an air hose with a brass nozzle was used in the final cleaning operations just previous to enameling. At times the workman would touch the fender with this nozzle, sometimes drawing it along the surface. To test the matter, a fender was selected and the nozzle was drawn several times across the surface. All of these lines appeared in the finished fender, showing through two coats of enamel, with the same appearance as before noted.

The same results were obtained in laboratory experiments. When the corner of a piece of brass was drawn with comparatively light pressure across a piece of sheet metal, which was afterward enameled and baked, the lines appeared through the enamel.

It would appear that small particles of brass worn off by abrasion against the harder sheet metal were sufficient to cause the above defects, but a magnification of 150 diameters failed to reveal any particles. However, when an iron nozzle was substituted for the brass one, the above defects disappeared.

Manufacture of Explosives in 1921

The Department of Commerce announces that the reports made to the Bureau of the Census show a decrease in the activities of the establishments engaged primarily in the manufacture of explosives during 1921 as compared with the year 1919. The total value of products amounted to $59,174,600 in 1921, and to $92,474,800 in 1919, a decrease of 36 per cent. Of the 109 establishments reported for 1921, 24 were located in Pennsylvania, 10 in Ohio, 9 in Oklahoma, 8 in Illinois, 7 in New Jersey, 6 in West Virginia, 5 in Kentucky, 5 in Missouri, 4 in Kansas, 4 in Texas, 3 in California, 3 in New York, 2 each in Alabama, Colorado, Indiana, Michigan, Tennessee, Washington and Wisconsin and 1 each in Arkansas, Iowa, Massachusetts, Minnesota, Montana, Utah and Wyoming. Of the establishments reporting in 1919, 11 were idle or out of business in 1921, 2 new plants being reported for the latter year.

The statistics for 1921 and 1919 are summarized in the following statement. The figures for 1921 are preliminary and subject to such change or correction as may be necessary from a further examination of the original reports.

	1921	1919	Per Cent of Decrease*
Number of establishments	109	118	7.6
Persons engaged	7,926	15,429	48.6
Proprietors or firm members	22	28	...
Salaried employees	2,426	6,152	60.6
Wage earners (average number)	4,478	9,249	51.6
Salaries and wages	$13,610,200	$25,749,200	47.1
Salaries	7,000,000	13,244,200	47.1
Wages	6,610,200	12,505,000	47.1
Paid for contract work	.....	30,500	...

Accelerated Reactions in Pulsating Gaseous Currents

Utilization of Pulsations and Vibrations of Appropriate Amplitude to Accelerate Physical Interchanges and Chemical Reactions Between Gases and Vapors in Checkerworks, Labyrinths, or Piled-up Solids

By Jules Deschamps* and J. F. Shadgen†

MECHANICAL improvements in the design and construction of rotating machines are enabling them gradually to displace similar devices having reciprocating movement. This is particularly true of pumps used for moving liquids or gases. Turbo pumps are supplanting plunger pumps everywhere and fan blowers are becoming more popular than compressors. Ejectors and injectors based on continuous kinetic expansion of gases are even more favored for the entire absence of moving parts. Uniformity of flow has always been considered a desideratum, and gas currents of constant intensity are preferred in all apparatus for blowing or circulation purposes and even in all problems of combustion, condensation, cooling and drying.

The main advantages of all rotary machines are simplicity and cheapness of construction. This is mostly due to the fact that no account need be taken of complications or forces due to inertia. But the efficiency of the rotary machines is usually lower than those built for alternating movement.

It is interesting to observe that nature, with its many complex machines, seldom uses continuous movements. Most physical and chemical actions of life are reciprocating or pulsating, from the walk of the animals to the flight of the birds and insects, from the respiration of the lungs to the circulation of blood in veins and arteries.

Use Continuous Flow for Transportation of Fluids

For the transportation of fluids in pipes there is no doubt that uniformity of flow is quite desirable. No one can contradict the superior advantage of a constant difference in pressure when liquids are to be moved. But if fluids when flowing through chambers are put in contact with other bodies in order to react physically or chemically or to be subjected to any transformation during the circulation, the optimum conditions may be altogether different.

In studying most engineering problems, average results have been derived from the tests of working machines and the solution of new problems based on simplified hypothetical considerations. Consequently the calculated results differ from the actualities. In order that we may approach the test results more closely, the designer uses many coefficients in his empirical equations, paying due regard to the peculiarities of each problem. This is especially true of working formulas used in computing the hydraulics of rivers and streams. Furthermore, when studying a gas within a given space, it is commonly accepted that within that volume both pressure and temperature are uniform at all points. This does not correspond to the conditions really existing; it is merely a gross approximation. For if the theory of probabilities is applied, the proportions of molecules having the same velocity can be calculated and the result leads to the inevitable conclusion that both temperatures and pressures differ considerably from one point to another. Considering that a lack of uniformity exists in simple gas analyses, it is easily understood that outside influences such as light waves or sound vibrations can modify the direct application of the law of Maxwell and consequently the whole equilibrium in the mass, as well as the reactions possible between its constituent elements or between them and other bodies at their natural contacts.

Let us consider some of the effects that can be produced by vibrations of about the velocity and amplitude of sound waves and also by pulsations of more moderate velocity. It is necessary to distinguish between these two types of periodic disturbances. The slow pulsations (produced by an alternative movement of a piston and of the order of one per second) create an increase of pressure, followed shortly afterward by a reduction, acting upon a considerable portion of the gas upon which they are impressed. On the other hand, the quick vibrations, measured by hundreds per second, change the relative distance between neighboring points sometimes no farther apart than the distance between adjacent molecules. Evidently no absolute line of separation exists between the two types of vibrations. Study of one type explains the other just as slow motion pictures illustrate the nature of rapid movements.

Take for instance a cooling or absorption tower filled with inert solids piled up regularly or irregularly. A fine rain of liquid sprays this packing material and drops toward the bottom. A gas or vapor rises from the bottom to the top. Contact between ascending gas and descending spray may produce physical effects such as cooling or solution, or on the other hand a chemical reaction may ensue.

Continuous Flow Produces "Dead Spaces" in Reactors

It is a common observation that there is an economical limit to the height of such towers beyond which the results are not increased in proportion to the expense involved. In other words, two towers of half the height will give a better efficiency than one very tall tower. This is explained by the fact that the descending liquid gathers in large drops after having passed through several layers of fillings no matter how fine and uniform is the original spray. These drops have a tendency to coalesce and the liquid finally streams along certain preferred channels, leaving large areas "dead." To counteract these conditions the tower packing would be divided in successive layers with a free space between them; the shape of the checkerwork has been carefully studied as well as the method of

*Paris, France.
†New York City.

piling. The results of all these palliatives has been disappointing, since the liquid eventually flows over the surfaces of the checkerwork while the gases ascend in the voids offering the least resistance. Hence bad contact and poor efficiencies result.

When a vapor or a gas is drawn through such tower by a constant difference in pressure, a certain equilibrium is established in the flow. All the gas does not rise from the bottom to the top with the same velocity through the various passages of the same horizontal cross-section, because the resistance due to friction on the walls or due to the downpouring liquid differs at these various channels, while the difference of pressure at top and bottom remains the same. Another cause responsible for variable speed in the various channels is the difference in effective cross-sectional area at various heights due to the shape of the piled-up bodies which in turn inevitably creates whirls and eddies.

If we consider a channel such as in Fig. 1 through which passes a stream of gas, it is apparent that the velocity in the sections *x*, *y* and *z* is different from those in the smaller sections *m*, *n*, *o* and *p*. It is doubtful that full expansion follows each restricted area and the equilibrium of flow will probably correspond to the dotted lines, thus illustrating that considerable portions of the contact surfaces are not at all well fed.

Again, consider a pile of irregular solids such as shown in Fig. 2. Two channels, 1-2-3, and 4-5-6 will have quite different average velocity. However, the pressure will be approximately the same at various heights. Consequently there will be little or no flow in the cross-channels 7, 8 or 9, particularly if they connect sections of a different area. Flow channels and surrounding eddies will form and the surfaces along cross-channels will be dead areas with small effect.

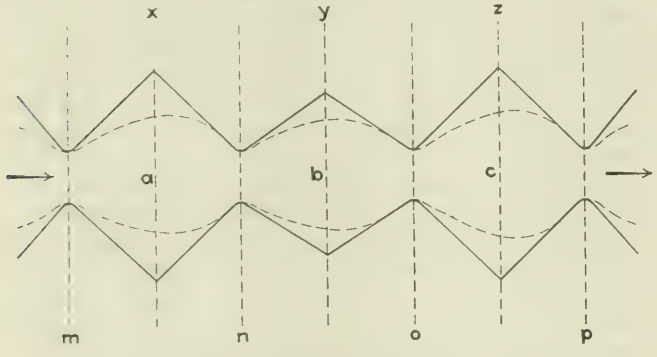

FIG. 1—FLOW OF GAS THROUGH A CHANNEL OF VARYING CROSS-SECTION

Analyze now in a similar way the phenomena produced by a variation of pressure, whether periodic or not, between the top and the bottom of the pile. By suddenly producing a greater difference in pressure any existing balance in the flow channels is overthrown. Channel 4-5-6 has fewer restrictions; therefore the pressure increase will be transmitted through it more easily than in channel 1-2-3. Consequently there will be produced a slight difference in pressure at the points 1 and 4, 2 and 5, and 3 and 6, which in turn will promote cross-currents sweeping through the transverse ways and supply them with fresh gas for reaction or absorption. Further, these lateral flows will also create whirls upon meeting the upward flow. If before these effects die out we suddenly produce a decrease in pressure, the same results will be created in the reverse direction. It follows that no real equilibrium can exist if the speed and amplitude of vibration is correctly chosen.

Every increase in pressure will force the gas into the tightest corners and at the opposite crest of the pulsation wave the products of the reaction will stream out of these dense parts. As these corners and labyrinths are the most drenched by a descending liquid or are those offering the largest surface of contact, the ultimate result will unquestionably be a much higher efficiency in the tower.

This analysis applies to cooling, volatilizing, concentrating or distilling operations—purely physical operations—as well as those chemical phenomena where gases or vapors react with each other in the presence of inert solids. If the gases or vapors passing through the shaft react chemically with the solids themselves (as in gas producers or blast furnaces), further consideration will indicate that the effects will be very similar. In such apparatus a continuous injection at constant pressure will create channels of least resistance through which the most of the gas will stream. But as the gases attack the solids in proportion to their contact surfaces, any restricted area will be widened very quickly. Lateral passages will then be even more ineffective than indicated in the diagram (Fig. 2); furthermore, the vertical channels may become coated by ashes or slags, offering strong resistance to further attack. If these chimneys or channels reach the top of the fuel bed in a gas producer, the air passes through and burns some of the gas already formed.

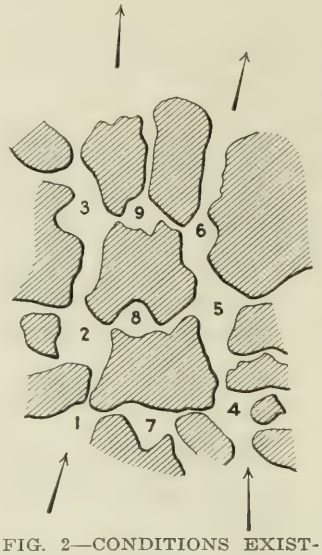

FIG. 2—CONDITIONS EXISTING IN A PILE OF IRREGULAR MATERIAL

To prevent this trouble these channels must collapse. Many recent improvements in producer design aim to favor these collapses by mechanical means (i.e., by stirring or plowing). If air streams up one or more of these large chimneys and if the piled-up solids between these channels are attacked to but a small degree, the zone of combustion is displaced, a poor gas with too much carbon dioxide is generated and coal is lost unburned in the ashes. Widespread disturbances in a blast furnace follow like causes. In order to avoid such bad effects, operators are forced to reduce the rate of blowing with consequent loss of production.

Pulsations in the air supply would force the air to penetrate into the whole mass of piled-up solids. Gases formed in the producer, such as CO and H, consequently cannot stay in the pockets, and corners and channels are not so easily produced. The solids are attacked from all sides simultaneously and the pile collapses by natural shrinkage. Hence producers will operate more regularly and with greater output when operating with pulsating current or blast.

If the solids to be attacked are of a porous nature, gas pulsations will produce additional advantages, since reactions inside the pores will be stimulated. In water-gas producers, for instance, steam is blown through hot

coke periodically. It can be reasonably expected that a pulsating jet will result in more rapid generation of hydrogen, and the correct object may be obtained by a steam injection of shorter duration.

A mixture of steam and air is injected into ordinary producers generating heating gas. By a pulsating current one may send the steam-laden air into the mass of hot coal at various pressures or, better, inject successively a current of dry air and a jet of air supersaturated with steam and give to these impulses variable durations. This latter method of operation will give the steam a better chance to act on the fuel superheated by the injection of dry air. It follows that periodic changes of pressure also create periodic variations of temperature. One may inject gas or vapor by different pulsations into many other industrial processes. If several constituents enter into the reaction, they can act successively or in variable proportions at periodic intervals. Favorable results can be foreseen for pulsations of relatively high frequency, even if the gases react on each other in the presence of catalytic solids.

In large industrial apparatus where gas is injected through several openings or tuyeres, such as an iron blast furnace, variation of pressure inside the mass and a change in the upward paths taken by the blast can be facilitated by dampening the tuyeres for intervals in rotation, thus producing an alternating movement in the gas in the reacting zones. This device may be superimposed on one which actually varies the pressure on the blast main.

Scope of the Process

It is obvious that each industrial application will require individual study to fix the amplitude and frequency of the pulsation promising best results. Attention may, however, be drawn to the fact that in several industries (such as when cooling of coke-oven gas) a sequence of towers is utilized. Pulsating devices attached to each tower may be operated in synchronism or not as seems desirable. By proper regulation, the towers can be operated like a set of lungs that are filled and emptied periodically.

An enormous field is thus laid open and remarkable combinations are made possible. Preliminary investigations on a commercial scale promise most interesting results. Pulsations of moderately long duration have been studied already. Rapid vibrations cannot be transmitted through a checkerwork because the height of an unobstructed channel must be in proportion to the period. In an ordinary tower, short vibrations create mutual interferences and the action is annulled when pressure changes move at different speed through various pathways. Pulsations must be of a duration to produce pressure differences throughout the entire mass; their frequency has to be in proportion to the time required by the gas to flow through the entire checkerwork. That is why the pulsations in gas producers should not be restricted to the steam alone, as the quantity of vapor blown is small as compared to the quantity of air entering the apparatus. Therefore a steam injection would be of too short duration to be of value.

To summarize, it may be said that the nature of the pulsations desired depends upon the effective height of the checkerwork or filling, upon the dimensions of the solids or bricks, and upon the speed of reaction characteristic to the chemical and physical phenomena involved.

The Story of the Production and Uses of Ductile Tantalum*

Within the Past Year Metallic Tantalum Has Been Produced Which Is Ductile and Malleable—Its Production Described and Its Possible Uses Forecast

By Clarence W. Balke
Fansteel Products Co., Inc.

IN THE year 1801 Hatchett discovered the oxide of a new metal in a black mineral which he obtained from the British Museum. He named the metal columbium and the mineral columbite, because the mineral originally came from Massachusetts. A year later Eckeberg made a similar discovery while working with some new minerals from Sweden, and he named the new metal which he discovered tantalum. Subsequently a number of other investigators announced the discovery of new metals in tantalum- and columbium-bearing ores which were all shown to be mixtures of these two, and in 1866 Marignac developed his classical method for their separation, which depends upon the difference in solubility of their double fluorides with potassium.

The first mention of tantalum in the metallic form is that obtained by Berzelius. In 1824 he obtained a very impure product containing not over 60 per cent of metal and having a specific gravity of 10 by reducing potassium tantalum fluoride with potassium. In 1902 Moissan produced a very hard and brittle form of tantalum high in carbon and having a specific gravity of about 12.8. In 1903 Dr. W. von Bolton, working in Germany, developed a process for the production of tantalum of sufficient purity to make it possible to produce drawn filament wire for incandescent lamps, and during the years 1905 to 1911 probably over one hundred million of these lamps were produced. This material as a filament wire was then replaced by tungsten.

About twenty years ago the writer became interested in these elements and devoted a number of years to the study of their various compounds and to the determination of their atomic weights. More recently, believing in the commercial value of this metal, an investigation was begun with the idea of producing the metal in commercial quantities. During the present year this investigation was brought to a successful conclusion and it is now possible to produce tantalum characterized by high purity and capable of being worked into sheet, rod or wire.

Occurrence of Tantalum

The elements tantalum and columbium are usually found associated with each other in their ores. The most important minerals containing these elements are columbite and tantalite, which are really iron salts of columbic and tantalic acids. Usually a part of the iron is replaced by manganese, and small amounts of titanium, tin and tungsten are almost always present. To lesser extent it occurs with rare earths in samarskite and other minerals.

For the production of metallic tantalum tantalite is the most desirable ore and should contain at least 60 per cent of the oxide and only a few per cent of columbium oxide.

The first step involved in the production of metallic tantalum is the extraction of pure compounds of tanta-

*Paper, slightly abridged, presented at the Richmond meeting of the American Institute of Chemical Engineers, Dec. 6-9, 1922.

lum from the mineral tantalite. This involves the separation of the columbium which may be present.

There are a number of methods available with which to attack this ore. As the most suitable method for the separation of tantalum from columbium is through the difference in solubility of the potassium double fluorides, the method employed should be directed toward the easiest method of production of these compounds. The pulverized ore may be fused with potassium bisulphate. On leaching this fusion, the acids of tantalum and columbium remain insoluble and can be dissolved in hydrofluoric acid and treated with potassium fluoride, or the mineral may be fused with acid ammonium fluoride and the tantalum precipitated from the solution of the melt by means of potassium fluoride.

A method which is more easily carried out on a large scale is the fusion of the finely pulverized ore with potassium hydroxide, which converts the tantalum and columbium into soluble columbates and tantalates. The filtered solution containing these salts may be treated with a mineral acid, preferably nitric or sulphuric acid, which precipitates the insoluble acids of tantalum and columbium. After washing, these are dissolved in hydrofluoric acid and the solution is treated with sufficient potassium fluoride to produce the double fluorides K_2TaF_7 and $K_2CbOF_5H_2O$. These two salts are readily separated by crystallization, inasmuch as the columbium salt is about twelve times as soluble as the tantalum double fluoride.

The oxide of tantalum can be produced from this double fluoride by treating the solution of the salt with ammonia, precipitating the acid, which can be washed and then ignited to oxide.

Production of Metallic Tantalum

It is perfectly evident at the present time that the early attempts to produce metallic tantalum, involving such methods as the reduction of the oxide with carbon in an electric furnace, the reduction of tantalum oxide with aluminum by the Thermit process or the reduction of the oxide by means of misch metal (mixed cerium earth metal), could not have given a product characterized by any degree of purity, and most certainly a metal which could not be subjected to any mechanical working.

Metallic tantalum powder can be produced by the reduction of the double fluoride with metallic sodium or potassium. It is impossible by this process to produce a powder characterized by high purity. For best results by this method the reaction should be carried out in a vacuum, the boats or crucibles containing the mixture of double fluoride and metallic sodium or potassium being placed in a tube or furnace which can be evacuated before the mixture is raised to the reaction temperature.

The product from this reaction can be treated with water and mineral acids in order to free the metal powder as completely as possible from adhering salt and other impurities. This powder is then compressed into bars and subjected to heat-treatment and finally fusion in a vacuum furnace, the high temperature of fusion eliminating the impurities which may be present. If this process has been completely successful, the fused metal will be found to be ductile and susceptible to mechanical working.

The most characteristic chemical property of tantalum is its unusual resistance to chemical corrosion. It is not attacked by hydrochloric or nitric acids or by aqua regia, either hot or cold. It is not attacked by dilute sulphuric acid at ordinary or more elevated temperatures, but appears to be slowly attacked by boiling concentrated sulphuric acid. Solutions of caustic alkalis do not attack the metal. Hydrofluoric acid seems to be the only chemical agent which will will attack it, and in the case of very pure metal and very pure hydrofluoric acid the action is very slow. A mixture of hydrofluoric and nitric acids will attack the metal with avidity, causing it to go into solution as tantalum fluoride.

If tantalum is heated in the air, the surface becomes blue at a temperature of about 400 deg. C. and at a somewhat higher temperature nearly black. Above a dull red heat the white oxide is produced and the metal gradually burns. This metal combines with avidity with hydrogen, oxygen or nitrogen. It will take up seven hundred and forty times its own volume of hydrogen, producing a very coarse-grained brittle product.

Tantalum containing dissolved gases will be harder than the pure metal and if their quantity is appreciable the metal may even be brittle, so that all annealing or heating operations with tantalum must be carried out in a vacuum. Tantalum burns readily when heated in chlorine gas, producing the volatile pentachloride. Solutions of chlorine, however, are without any action on the metal. Tantalum is not affected by any of the chemicals or antiseptics used in dentistry or surgery probably without exception.

Physical Properties of Tantalum

It has been possible to produce metallic tantalum of an exceedingly high degree of purity, and to produce it in commercial quantities, having a purity of at least 99.5. The pure worked material resembles platinum very much in color and appearance. Its melting point may at present be taken as 2,850 deg. C. The specific gravity of the worked metal is 16.6. The pure metal is characterized by toughness and by its great ductility and malleability.

It has been found possible to reduce a bar of tantalum about $\frac{3}{8}$ in. in diameter to wire of only a few mils in diameter without any intermediate heating to the annealing or equiaxing temperature, although the material is subject to strain hardening, resembling the more common metals such as silver or copper in this respect. Tantalum, however, resembles tungsten and molybdenum in that they may all be worked severely at temperatures below their equiaxing temperatures. Copper and silver may be worked at room temperature, but these metals become quite rapidly strain-hardened so that a further reduction makes it necessary to anneal the metal. Tungsten and molybdenum must be worked at elevated temperatures in the early stages and if they are to be worked at room temperature in the finer sizes any operation corresponding to ordinary annealing must be avoided. Tantalum may be worked at room temperature to a remarkable extent without annealing.

The tensile strength of drawn tantalum wire may reach 130,000 lb., which is considerably more than that of hard drawn copper, nickel or platinum, but less than that of molybdenum or tungsten.

The linear coefficient of expansion is more than that of molybdenum or tungsten and only slightly less than platinum. For this reason it is possible to seal tantalum into glass.

The electrical resistance is quite high, about eight times that of copper and about three times that of tungsten. The accompanying table gives the physical prop-

	Tungsten	Tantalum	Molybdenum	Platinum	Copper	Nickel

erties of tantalum as far as they are at present known, and also those of a number of other metals in comparison.

High Chemical Resistivity Gives It Many Uses

In considering the possible uses for this metal we must take into account its high melting point, its resistance to chemical corrosion and its tendency to absorb all of the common gases. We must also remember that we are limited by its relatively low temperature of oxidation. Tantalum seems to be a very desirable metal for the manufacture of certain dental instruments and dental spatulas, and undoubtedly for other dental and surgical tools or instruments. The metal is not attacked by any of the antiseptics or chemicals used and can be readily sterilized by heat. A surface film of hard material about as hard as agate can be produced on the metal by proper heat-treatment. It will probably be found possible to harden the material throughout, thus combining all the advantages of tempered steel with absolute chemical inertness.

It has been suggested for use in the manufacture of pens and analytical weights. Its use in chemical laboratories and in the chemical industries as containers, parts of pumps and other equipment will undoubtedly depend upon the cost at which the metal can ultimately be produced.

Tantalum is suitable for cathodes in electrochemical analysis. In some respects it is more suitable than platinum. For instance, zinc may be plated directly upon the tantalum, as it does not alloy with the metal. Gold or platinum can be deposited upon the metal, as they can be removed by aqua regia without attacking the electrode.

Undoubtedly tantalum in the form of sheet, wire or ribbon will find application in the manufacture of radio sending and receiving tubes. The property of tantalum of absorbing gases would seem to make the metal its own "getter" in vacuum tubes, and would tend to maintain the high vacuum required, particularly in the sending tubes. It would seem that some part of the lamp made of tantalum could be so constructed that at all times a portion of the metal would be at the proper temperature to absorb gas and would, therefore, tend to maintain a vacuum equilibrium within the bulb.

Use of Tantalum as an Electrolytic Valve

Tantalum has interesting possibilities on account of its property of acting as an electrolytic valve.

If two plates of bright tantalum metal are placed in an electrolyte and the two plates connected to an electric battery, there is an instantaneous flow of current similar to that between plates of the better known metals. Within a few seconds the current flow will drop to a very small comparative value, providing the battery voltage is not too high. The order of the current flow will become that of 1 milli-ampere and less with impressed direct current voltage up to 75 volts when sulphuric acid of the strength ordinarily used for storage batteries is the electrolyte. This drop in current flow will be accompanied by the formation of a film on the tantalum anode, presumably of tantalum oxide. This film often shows beautiful iridescent colors.

If a tantalum plate and a lead plate are placed in an electrolyte and a source of alternating current of the usual commercial frequency is connected to the tantalum and lead plates, the current flow in one direction will be almost entirely shut off and a pulsating direct current will be obtained. In such a set-up this flow of current is accompanied by electrolytic action with evolution of hydrogen gas at the tantalum and oxygen at the lead. The action of the tantalum is, therefore, such that electrons are permitted to flow from the tantalum to release hydrogen ions but are prevented from passing from oxygen ions into the tantalum.

The current derived from this apparatus may be utilized for charging storage batteries, for the electrodeposition of metals, and various other electrochemical actions requiring a direct current.

It is possible, by using two tantalum electrodes in a single cell, so to rectify the current that both half waves of alternating current pass in the same direction. This current may be smoothed out by a suitable series of inductances and capacities to give what is practically a constant direct current.

The efficiency of tantalum as a valve with respect to leakage of the current varies with the impressed voltage, with the electrolyte, current density, etc. Due to the fact that tantalum is very inert toward the chemical action of solutions, there is a wide choice of electrolytes and the life of the tantalum appears practically unlimited.

For a charging set-up with a 6- to 8-volt battery the energy efficiency is approximately 33⅓ per cent, which compares favorably with rectifiers of the hot and cold electrode type and the mechanically vibrating rectifiers.

The tantalum battery charging rectifier is noiseless in operation, has no moving parts and requires attention in only one matter, which it has in common with the storage battery itself—that of distilled water being added to replace evaporated and decomposed water of the electrolyte.

In addition to functioning directly as a rectifier for obtaining continuous current, apparatus built along similar principles may be used for electrolytic condensers and electrolytic detectors and possibly lightning arresters.

Among other metals which have this property of valve action more or less in common with tantalum are magnesium and aluminum. However, owing to the ready susceptibility of both these metals to chemical corrosion, they have not proved very suitable as sources of direct current. Condensers and lightning arresters for high potential transmission lines are commercially used with aluminum plates.

Recent Chemical & Metallurgical Patents

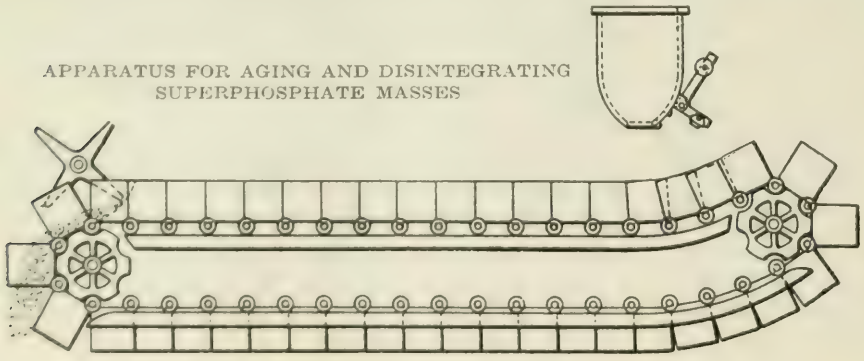
Drying Nitrogen and Hydrogen Prior to Synthesizing Ammonia—F. W. de Jahn of Norway has patented the use of alkali amides such as sodamide as a drying agent for nitrogen and hydrogen gases prior to ammonia synthesis. This is a corollary of his general patent (Serial 200,047) on the synthetic production of ammonia under pressure of 1,400 lb. The drying of the gases takes place at this pressure and no temperature control is necessary. (1,436,949. Nov. 28, 1922. Assigned to Atmospheric Nitrogen Corp. of N. Y.)

Elimination of Phosphorus From Refractory Metals—Ira Paul of Brooklyn has assigned to the Metal & Thermit Co. a patent by which, it is claimed, phosphorus can be separated from vanadium, chromium, uranium and molybdenum and other so-called refractory metals. The process consists in bringing the ore into solution by one of the usual methods and acidifying the filtrate with mineral acid. Alkali is then added until siliceous material is precipitated. After filtration more alkali is added until the solution is only very slightly acid. Alum is then added, and an oxidizing agent such as nitrate, chlorate, etc. The desirable metals are precipitated and may be filtered away from the solution, which contains all the phosphorus in combination with aluminum. (1,437,191. Nov. 22, 1922.)

Process for Aging and Disintegrating Superphosphate Masses—G. A. Bruhn has assigned to the Krupp Co., of Germany, a method for disintegrating and aging superphosphate masses. At present, it is customary to age superphosphate in aging chambers, which permits the crude phosphate and sulphuric acid, after mixing in suitable kettles, to stand for some time. The figure given shows the principle upon which the new apparatus works. The trough conveyor receives the charge from the mixing kettle and allows the material to set in relatively small quantities and the aging thus takes place more quickly than under the old system. It will be noted that as the mix comes down from the kettle onto the conveyor it is forced to spread in the direction in which the conveyor moves, due to the elevation of the charging end. When the mass reaches the discharge end of the conveyor, it is cut with knives or wires and is then ready for storage prior to final mixing. (1,430,621. Oct. 3, 1922.)

Calcium Arsenate Manufacture—C. B. Dickey, assignor to the Pittsburgh Plate Glass Co., has developed an improvement in the manufacture of calcium arsenate. At present arsenic acid is added to a milk of lime suspension and the calcium arsenate thus produced often contains as high as 2 per cent soluble salts of calcium. These are undesirable, inasmuch as they poison the cotton or other plants on which the substance is used as an insecticide. In order to prevent this formation of soluble salt, ordinary salt from 1 to 5 per cent is added to the milk of lime suspension, which produces a suspension of lime containing a concentration of calcium hydrate in actual solution (solution concentration) higher than normal for that temperature of solution. The soluble arsenate is thus reduced to less than 0.5 per cent and if 0.5 per cent of the soluble salt is permitted to remain in the product, it seems to prevent the formation of soluble calcium salt upon standing. In a subsequent patent, No. 1,428,946, issued Nov. 7, 1922, the process of eliminating soluble calcium salt from calcium arsenate already prepared by the usual method is described and consists essentially in adding to the suspension of the calcium salt some ordinary salt. This, as before, increases the solution concentration of $Ca(OH)_2$ and eliminates soluble arsenates. The basic patent was issued Sept. 12, 1922, No. 1,428,650.

APPARATUS FOR AGING AND DISINTEGRATING SUPERPHOSPHATE MASSES



American Patents

Issued Dec. 12, 1922

The following numbers have been selected from the latest available issue of the *Official Gazette* of the United States Patent Office because they appear to have pertinent interest for *Chem. & Met.* readers. They will be studied later by *Chem. & Met.'s* staff, and those which, in our judgment, are most worthy will be published in abstract. It is recognized that we cannot always anticipate our readers' interests, and accordingly this advance list is published for the benefit of those who may not care to await our judgment and synopsis.

1,438,183—Conveying Apparatus.
1,438,190—Grate for Stokers.
1,438,194—Extraction of Grease From Solids.
1,438,221—Manufacture of Linoleum.
1,438,258—Retort Bench and Process of Operating Same.
1,438,342—Reverberatory Furnace.
1,438,357—Extraction of Uranium and Radium.
1,438,421—Oil-Shale Retort.
1,438,471—Wood Impregnation.
1,438,502—Concentrating Liquid Containing Organic Matter.
1,438,537—Separation of Coke From Slag.
1,438,542—Process for Producing Carbon Black.
1,438,558—Recovery of Caffeine.
1,438,565—Recovery of Gaseous Constituents of Oils, etc.
1,438,581—Manufacture of Compressed Hydrogen.
1,438,643—Recovery of Zinc.
1,438,710—Purification of Naphthalene.

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

British Patents

For complete specifications of any British patent apply to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Artificial Silk—A spinning bath for use in the manufacture of artificial threads from viscose consists of an aqueous solution of the acids obtained by sulphonating the condensation products prepared by reacting with phenols on aldehydes and ketones, especially ketoses, aldoses, and more especially the various carbohydrates. The bath may also contain mineral acids or the salts of mineral acids and the soluble salts of the sulphonated acids. With these baths, satisfactory results are obtained even with entirely unripened viscose. In an example, a bath for use in making threads of about 2 deniers contains 10 per cent sulphuric acid, 8 per cent Neradol and 10 per cent sodium sulphate; the bath is maintained at 18 deg. C., and a spinning length of 40 cm. with a normal speed of drawing is employed. (Br. Pat. 184,449; not yet accepted. A. Kämpf. Premnitz. Oct. 4, 1922.)

Artificial Silk—Another bath consists of an aqueous solution of the acids obtained by sulphonating the resinous condensation products prepared by reacting with phenols on wood in the presence of acid catalysts. To the bath, mineral acids may also be added, or the acid may be partly neutralized, or to the bath may be added the salts of mineral acids or of the sulphonated acids above referred to; with these baths, satisfactory results are obtained with entirely unripened viscose. In an example, the bath contains 10 to 12 per cent sulphuric acid, 5 per cent sulphonated acid and 15 per cent sodium sulphate; and a spinning speed of 50 meters and a length of bath of 50 cm. are employed. (Br. Pat. 184,450; not yet accepted. A. Kämpf, Premnitz. Oct. 4, 1922.)

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields
Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Bureau of Chemistry Emphasizes Achievements

Work of Color Laboratory, Carbohydrate Laboratory and Naval Stores Division of Benefit to Important Industries

IN THE MATTER of appropriations for scientific and technological work, Congress is demonstrating less parsimony than was the case a year ago. Practically all of the technical and scientific bureaus are being allowed small increases.

In justifying the appropriations, representatives of the various bureaus have appeared before the appropriations committee to point out the results of their investigations and to indicate the need for continuing the work. W. G. Campbell, the acting chief of the Bureau of Chemistry, laid emphasis on the importance of the work being done in the Bureau's color laboratory. "One of the greatest difficulties confronting the industry in color manufacture," Mr. Campbell told the committee, "is some means by which there can be a definite and correct identification made of colors. We have been working upon methods of identification by which, upon proper analysis, definite colors can be identified and the extent of the impurities made known." He pointed out that some of the work of the color laboratory "has effected tremendous economy in the manufacture of some of these color products or the basic material from which they are made." He cited the work on phthalic anhydride. He also described in detail the efforts being made to develop a stable biological stain. With regard to the manufacture of synthetic thymol.

"This product has been brought exclusively from abroad, but we have found it possible to manufacture from cymene a synthetic thymol which seems to have every attribute of the product upon which we have depended heretofore. Thymol now sells for $4.50 a pound. We calculate it can be made in this synthetic fashion for $2.50 a pound. When it is considered that two million gallons of cymene are wasted each year in the paper factories of this country and of Canada, the economic significance of that work is apparent."

Research on Sugar

H. S. Paine, in charge of the carbohydrate laboratory, told the committee in detail of the very extensive work which the Bureau has done in the development of more effective methods in the manufacture of sugar and syrups. The Bureau has made possible, he said, the use of invertase in the manufacture of cane syrup by methods devised to prevent fermentation on one hand and crystallization on the other. These methods have been seized upon enthusiastically in the cane syrup-producing sections, it was stated. In addition the Bureau is working on a number of the technological difficulties with which the sugar manufacturing interests are confronted. In co-operation with the producers a uniform grade for cane syrup is being developed. Methods also are being developed whereby more sugar can be obtained from the final beet-sugar molasses. "We have been studying this problem and have been making considerable progress," said Mr. Paine. "We hope before long to develop means of making the process practically 100 per cent efficient."

Naval Stores

Dr S. P. Veitch told the committee of the work being done on naval stores. "Rosin," he declared, "is being substituted more and more largely for fossil resins in the manufacture of varnishes and paints. This is due to the fact that these resins are becoming scarcer and are selling for higher prices. Then too, we are learning to use rosin more successfully, modifying it to take the place of resins."

The work of the Bureau also deals with the question of adulteration and misgrading in both rosin and turpentine. In regard to the turpentine situation, Dr. Veitch said: "Turpentine is selling around $1.50 a gallon in the South. By the time the individual user buys it he pays $2 or more a gallon for it. That induces adulteration with material which costs twenty or thirty cents a gallon. Adulteration is increasing some in the South but most of it is taking place in the paint-using districts. In some states I have found, in asking for turpentine, that I have been delivered mineral oil without a bit of turpentine in it. The high prices have driven turpentine from the market in places."

Sodium Nitrate for Sale

The government has called for bids for 10,017 tons of sodium nitrate held in storage at Nitro, W. Va. The material is offered in lots of 100 tons or more. Bids will be received by the Ordnance Salvage Board, Army Building, 39 Whitehall Street, N. Y., until noon, Jan. 8.

Contemplate New Survey of Chemical Schedule

The Tariff Commission is considering a complete survey of the chemical, agricultural and several other schedules of the new tariff act, affecting which several applications for changes in rates of duty have been filed under the flexible tariff section. Decision as to whether this policy shall be pursued by the Commission will be made after the first of the year.

Several members of the Commission are said to feel that to take up first one application and then another, without regard to the schedule affected, and decide their merits individually without reference to the other paragraphs of the same schedule which might be affected would throw the schedules out of balance.

It has been suggested that the schedules in which the greatest number of applications for changes have been made—chemical and agriculture—be surveyed as a whole, with the applications in mind and also with the purpose of detecting other possible weaknesses which might be disclosed by such a survey and corrected on the initiative of the Commission itself.

The objection to this suggested system of handling the flexible tariff section is that a complete survey of any one schedule would consume months of time and that all relief in specific cases would thereby be held up.

Increase in Helium Appropriation Approved by House Committee

An indication of the value attached to helium for Army and Navy use is had in the approval by the Committee on Appropriations of the House of Representatives of the $6,290,000 appropriation from which the funds are drawn for the operation of the helium plant. This is an increase over the amount allowed in the last Navy appropriation bill and will permit of the continuous operation of the Fort Worth plant during the next fiscal year. The plan includes the production of 12,000,000 cu.ft. of helium. Admiral Moffett, testifying before the committee, declared it is essential to have a larger helium supply as it would not be wise to make any further use of hydrogen in the larger ships at this time, as another accident would deal a heavy blow to the whole lighter-than-air program. At the present time the combined helium stocks of the Army and Navy is 1,822,000 cu.ft.

Annual Meeting of the New Jersey Clay Workers Association

Session Is Signalized by a Symposium on the Casting of Ceramic Bodies and a Discussion on the Oil Firing of Kilns for Textile Porcelain, Tile and Terra Cotta

THE ANNUAL meeting of the New Jersey Clay Workers Association and Eastern Section of the American Ceramic Society was held in the assembly room at the new Ceramics Building, Rutgers College, New Brunswick, Dec. 12. More than 100 members and guests were present from all parts of the state, with visitors from other sections.

The morning session was given over to a symposium on the casting of ceramic bodies, and the afternoon to a similar discussion on the oil firing of kilns, both being particularly pertinent topics at this time with labor troubles and difficulty in obtaining coal.

Following regular routine business, President R. H. Minton, General Ceramics Co., Metuchen, N. J., gave an interesting presidential address in the form of a paper dealing with the ceramic history of New Jersey.

Casting of Ceramic Bodies

The symposium was opened by Andrew Foltz, president of the Lambertville Pottery Co., manufacturer of sanitary ware. He described the installation for handling the slip at this plant, the particular departure being in the use of an air compressor for moving the body from the tank to the shops instead of a pump. There is no agitator in the tank and the natural supposition that the slip would be full of air in its flow through the pipes to the shop apparently does not hold; it has worked with entire success.

The tank is operated by air at about 85 lb. pressure. It is provided with an arrangement for blowing the slip back into the blunger, instead of through the fly pipe to the shop, where such is necessary. The tank, below the floor level, is provided with a float or gage to show the amount of slip it contains. The ceramic body used for the manufacture at this plant runs as high as 18 per cent ball clay.

The next speaker, C. S. Maddock of the Thomas Maddock's Sons Co., likewise a manufacturer of sanitary ware, explained the system used at this plant. It employs the Wainford-Darling equipment, with the addition of a pressure valve and return system, both of which have proved very advantageous.

The pipe runs through the shop and there is a common return to the agitator. The slip is delivered to every man by a hose. An overflow system has been installed and many previous troubles have been eliminated, principally pump action regulated and full supply of slip to the men at all times.

Mr. Maddock spoke of the difficulty in casting wares over 1 in. thick, through balling of the body, which causes cracks, and urged that suitable research be carried out in this direction.

Following this speaker, Eric W. Turner, Trenton Flint & Spar Co., read a brief paper on the casting of grog bodies. He said that a cast sagger will carry the load better than either a hand-made or machine-made sagger. It will probably cost a little more, but is well worth it. In the preparation of the grog slip for this service, sodium silicate and carbonate are used as electrolytes, and the proportions depend upon the physical properties of the clay.

A grog slip, it was pointed out, cannot be handled in pipes on account of the friction, and it must be carried to the molds in a suitable vessel and there poured. The molds are of plaster. With regard to the time element, it was stated that shapes up to 1½ in. in thickness may be cast in the same mold every 6 hours, while those from 4 to 6 in. thick require from 16 to 24 hours.

T. A. Klinefelter, Trenton Fire Clay & Porcelain Co., outlined briefly his experience in casting electrical porcelain. He said that it had been found very quickly that the ordinary high-tension body for jiggering was not a good body for casting; on the contrary, it was a very poor one. Pieces to be cast, as a rule, were of very difficult design, such as bushings with heavy corrugations and the like—material that would hang in the mold. Sanitary bodies were tried, but of course these were too porous to stand up under the necessary electrical test. The balling effect in pieces over 1 in. thick, referred to by Mr. Maddock, was another trouble encountered. With such unsatisfactory results, the casting method, he said, was discontinued.

Calcining Solves Difficulties

In commenting upon the last speaker's difficulties, T. A. McDougal, Champion Spark Plug Co., said that a solution to the problem was the calcining of the porcelain body; it is then ground and introduced into the slip to be used for casting. The matter of calcining, he set forth, was being carried out successfully in the spark plug industry, 45 to 50 per cent of the body being so treated and reduced to pass through a 120-mesh.

Frank Dinsmore, Imperial Porcelain Works, Inc., manufacturer of electrical porcelain, said that this plant was casting wares with complete success, the pieces being 2 to 2½ in. thick, and with practically no loss through cracking. An open mold is used for this work. Additionally, pieces 7½ to 8 in. in diameter and 25 to 26 in. long are also being cast, some of these being quite intricate, with corrugations the entire length. In concluding his remarks, Mr. Dinsmore said that the open mold casting method is the only one which will handle the variations in thickness satisfactorily and bring the desired results.

Presentation of Picture for Ceramics Building

Prior to the adjournment for luncheon, Ross C. Purdy, general secretary, American Ceramic Society, presented a large picture of Edward Orton, Jr., the dean of the ceramic industry, to the Rutgers ceramic department. This picture, mounted in an attractive gold frame, was obtained through subscriptions from the former pupils of Dr. Orton, and will hang in the assembly room.

Election of Officers

Officers were elected for the coming year as follows: Andrew Foltz, Lambertville Pottery Co., president; Charles W. Crane, the Crossman Co., vice-president; Prof. George H. Brown, director of the department of ceramics at Rutgers College, secretary and treasurer; the latter has held this office for a number of years.

Kiln Firing and Relative Fuel Values

Following a luncheon, served in the basement of the Ceramics Building, the afternoon session was opened with President-elect Foltz in the chair, the first address being on the subject of "Kiln Firing and Relative Fuel Values," by Francis W. Walker, Jr., Beaver Falls Art Tile Co.

Mr. Walker explained that owing to the disturbed fuel markets, his company had experimented with coal, gas and oil, and had made careful tabulations of the results obtained from each fuel and its relative value in actual operating service. The success with any fuel, he pointed out, depends largely upon the character of furnace and its design, as well as upon the equipment used. For instance, in the case of gas, the consumption is proportionally greater in the up-draft kiln than in those of the down-draft type. The average coal consumption for seventy-three 16-ft. down-draft kilns was 12.8 tons, whereas the gas consumption for these same kilns averaged 360,000 cu.ft., which if expressed in B.t.u., figuring coal at 14,000 B.t.u. per lb. and gas at 1,000 B.t.u. per cu.ft., shows a thermal variation of less than one-half of one per cent.

Taking typical figures for a month, this being September, 1922, it was shown that the total cost of coal firing was $13.14 per ton, including the price per ton, labor cost, maintenance and sagger breakage; in the same month the cost of gas firing, using 28,000 ft. of gas at 45 cents per thousand, was $15.10; and the cost of oil firing, using 197 gal. of oil at 6¼ cents, was $15.69. These results, expressed in terms of percentage, were as follows:

	Coal	Gas	Oil
Fuel	46.2	83.5	78.2
Labor	20.4	6.9	6.6
Maintenance	10.8	1.6	5.5
Sagger breakage	22.6	8.0	9.7
	100.0	100.0	100.0

NEW JERSEY CLAY WORKERS ASSOCIATION AT NEW BRUNSWICK

The average cost of firing with the respective fuels are as follows, showing oil to be the most expensive: Coal, $12.84; gas, $15.25; and oil, $16.59. The problem in the case of gas and oil is one of purchasing economically, while in the matter of coal, all items must be considered, especially that of labor, on account of the disagreeable nature of the work and the overlapping of responsibilities caused in the different working shifts of 8 to 12 hours each, as the case may be.

The application of pyrometric equipment becomes of utmost necessity, particularly when firing with coal. If but a single record is taken, only limited control is possible, and it becomes necessary for the fireman to judge his work in the other parts of the kiln by comparison. Where possible, this should be overcome with the use of either the optical pyrometer or a four-point recorder, a couple in each quarter of the kiln, or both. With regard to the effect of the fuels upon the quality of the ware, Mr. Walker said that he was firmly of the opinion that with very few exceptions equal results can be secured with each character of fuel.

Oil Firing for Textile Porcelain

John A. Williams, Mitchell-Bissell Co., the next speaker, set forth that the use of oil fuel had proved highly successful at his company's plant, which has been operating by this method since early in 1920. The company specializes in the production of porcelain guides for textile mill service.

He said that all equipment had been purchased in duplicate to avoid any possibility of shut-down through failure of apparatus. This includes two oil pumps, two air blowers, two strainers, and so on. Each kiln at the plant is provided with six burners, with air piping, air gage, valves, etc., costing about $300.

The product is a highly vitrified one; it is fired to cone 12 in one burn—that is, the body and glaze are handled all at one time—and results are being obtained with oil fuel that could not, in Mr. Williams' opinion, be duplicated with coal. One man is handling three kilns at this pottery. Two different size tips are used on the oil burners, the smaller one being employed at the beginning of the burn and until its near-maximum is reached, at which time the change to the larger one is made.

On a 13-ft. kiln, using six burners, with an average burning of 44 hours, about 1,760 gal. of oil was consumed for each burn over a period of a year; on a 14-ft. kiln, with eight burners, the average is from 2,300 to 2,400 gal. of oil per burn of 42 or 44 hours. At the present time a price of 7 cents a gallon is paid for the highest grade fuel oil, 36 to 40 deg. Baumé, delivered at the plant. Four pyrometer tubes are installed in each kiln, one in each quarter; also, an indicating instrument is placed in the kiln shed for the guidance of the fireman at all times.

Oil Firing for Tile

Donald Hagar, Mosaic Tile Co., gave a comprehensive outline of the installation for oil burning at this plant, utilizing a low-pressure system, or with air pressure never exceeding 2½ oz., volume, rather than pressure, being relied upon to supply the necessary air for combustion. The pressure on the oil varies from 30 to 45 lb., as the conditions warrant.

All the burners are fitted with mixers for admitting auxiliary air, providing a further regulation for lengthening or shortening the flame. A rotary pump delivers the oil from the storage tank through a heater and thence to a 1-in. circular pipe which surrounds each kiln, and then to the burners through ⅜-in. outlets in each pipe.

Two important factors to be considered were mentioned, these being the atomization of the oil and the amount of air admitted to the burners. The effect of poor atomizing is to facilitate the formation of carbon in the fireboxes and to produce incomplete combustion. This condition can be prevented by controlling properly the temperature and the pressure. With respect to air supply, it was pointed out that the amount of air supplied to the burners bears a distinct relation to the amount of oil consumed. A deficiency in air produces incomplete combustion, while an excess will shorten and intensify the flame, thus using more oil than necessary.

In speaking of the advantages of using fuel oil, Mr. Hagar listed these as a comparison with coal, enumerating as follows: (1) Produces a more intense heat, thus cutting down the burning time; (2) the kiln is regulated more easily, affording a more uniform burn; (3) less labor is required; (4) less space required around the kilns; (5) makes for a cleaner kiln shed; (6) smaller storage space required; and (7) no strikes to interfere with the supply.

With regard to cost, he stated that a rough estimate would show that it cost about $10 more to burn the bisque kilns at the plant with oil than with coal. On the other hand, the cost is reversed in favor of the oil in the same ratio in the glaze kilns.

Oil Firing for Terra Cotta

G. M. Tucker, New York Architectural Terra Cotta Co., gave a brief résumé of the installation at the plant of his company and the results being secured through the use of oil fuel. One of the greatest advantages, he said, was the ease of control of the fires at any stage of the burn, giving a pyrometric curve that is very regular, without the peaks and depressions as found in the case of coal.

The equipment at his plant consists of five depressed oil reservoirs, varying from 10,000 to 25,000 gal. capacity, small duplex pump, and auxiliary piping and apparatus. The oil burner used is of the internal mixer type, in which the oil and air or steam mix before leaving the nozzle. Compressed air is used as the atomizing agent, and the oil employed varies from 18 to 20 deg. Baumé. Mention was made of the advisability of installing equipment in duplicate for emergency service.

The last speaker in the symposium was C. F. Geiger, of the Carborundum Co., who gave a digest of the use of the refractories manufactured by this company for various character of oil-burning service.

Among the speakers of the afternoon session, Ross C. Purdy, general secretary of the American Ceramic Society, tendered an interesting address on the value of technical research, saying that for every dollar so expended many fold return came to manufacturers of ceramic products and the industry as a whole. Mr. Purdy also spoke briefly on the work and aims of the American Ceramic Society.

Denaturing Provisions Make Prohibition Enforcement Easier

Specifications of Benzol Required for Denaturing Alcohol for Rubbing Purposes

With the new regulations affecting changes in formulas for denaturing alcohols for rubbing purposes in operation, the prohibition unit of the Treasury Department believes that practically all has been done that can be safely done to relieve the industrial alcohol business from any possibility of connection with the illicit liquor traffic.

The new regulations, prepared by Dr. Doran of the industrial alcohol division of the prohibition unit, provide that three-eighths of one per cent of benzol shall be mixed with alcohol intended for rubbing purposes. The benzol is difficult to remove and it is easily detected by taste, yet does not injure the alcohol for rubbing purposes.

"Benzol sends its own warning through the sense of taste," said Dr. Doran. "Of course the easiest way to denature alcohol is by use of wood alcohol, but this is both odorless and tasteless and it is this fact which leads to death and injury when chances are taken. The object of denaturization, as we conceive it, is not to murder but to warn."

The specifications for benzol which hereafter must be used in the three formulas of odorless alcohol affected by the order are:

SOLUBILITY

When 10 c.c. of benzol are shaken with an equal volume of water in a glass-stoppered cylinder, divided into tenths of a cubic centimeter, and allowed to stand five minutes to separate, the upper layer of liquid must measure not less than 9.5 c.c.

BOILING POINT

When 100 c.c. of benzol are subjected to distillation in the same manner as described for the boiling point of wood alcohol, not more than 1 c.c. should go over at 77 deg. C., and not less than 95 c.c. at 85 deg. C.

This order, which went into effect December 6, removes the last of the major causes of complaint that industrial alcohol was being denatured and used for purposes violative of the prohibition amendment, according to Dr. Doran.

RECOGNIZE EFFORTS OF INDUSTRY TO CONFORM WITH LAW

The industrial alcohol interests have been striving earnestly to remove their business from any connection with the illicit liquor traffic. Of the approximately 70,000,000 proof gallons of industrial alcohol produced in the United States last year, something more than 50,000,000 proof gallons were completely or partially denatured by the more than 70 formulas, and there were withdrawals of only approximately 3,000,000 proof gallons of the class which caused the trouble to the prohibition unit, and only a small fraction of this was used fraudulently.

ENFORCEMENT BECOMING EASIER

Wholesale and retail druggists are co-operating with the prohibition unit, through their associations, to help drive out the undesirables, the officials report. It is being made more difficult for so-called wholesale druggists to start business in order to become wholesale whiskey dispensers. When the prohibition amendment first became operative, there was considerable trouble with such camouflaged concerns, which started up business in all sections of the country. For the first time, the drug stock jobber made his appearance in the United States. Also, some of the new firms sold drugs at cost, or less, to encourage their liquor business.

These things are being overcome, the prohibition unit reports, and legitimate druggists are assuming command of the situation and following the law closely.

This, with the general improvement in the industrial alcohol situation, is making administration of the prohibition laws much easier and at the same time placing legitimate business on a plane safe from the business pirates who threatened it.

Bureau of Standards Bids Stratton Farewell

A farewell reception in honor of Dr. Samuel W. Stratton, director of the Bureau of Standards and president-elect of Massachusetts Institute of Technology, was held at the Bureau on Dec. 14.

The formal reception, in the industrial building, was followed by a trip through the various laboratories. A collection of exhibits from other buildings had been assembled on the third floor and attracted many of the visitors from the floor below where the U. S. Marine Band was furnishing splendid dance music.

Dr. Stratton has been Director of the Bureau since its establishment in 1901. The sentiment of his staff is well expressed by the following words of appreciation.

> The Bureau is an enduring monument to Dr. Stratton and those who through the early years of development stood for high standards of effort and attainment. Nations and industries, inspired by the Bureau, are founding similar institutions. Endowed research and industrial standardization have grown apace with the Bureau. Within its walls hundreds have been trained. From its staff industry recruits experts, and they carry the spirit of creative research which it is our privilege to cherish. In leaving us, our chief will prize most our assurance that we shall keep burning steadily and pass on undimmed the torch of inspired effort. That torch gives energy and enlightenment—two essentials of life and industry.

E. C. Franklin Elected President of A.C.S.

Bancroft and Hoskins Chosen as Directors—Four Councilors-at-Large Also Elected

Edward C. Franklin, professor of organic chemistry of Leland Stanford Junior University, has been elected president of the American Chemical Society, succeeding Edgar F. Smith of the University of Pennsylvania.

Wilder D. Bancroft of Cornell University was reelected a director of the society and William Hoskins, consulting chemist of Chicago, was made a new director of the society. The following councilors-at-large for the period from 1923 to 1925 also were elected: Roger Adams, University of Illinois; G. N. Lewis, University of California; Ralph H. McKee, Columbia University, and Dr. William McPherson, Ohio State University.

Dr. Franklin, the new president, was born at Geary City, Kansas, in 1862. He was graduated from the University of Kansas in 1888 and received his master's degree in 1890. He was a student at the University of Berlin in 1890 to '91 and received his Ph. D. at Johns Hopkins University in 1894.

He was a member of the advisory board of the Bureau of Mines in 1917 to '18; physical chemist of the Bureau of Standards and consulting chemist of the ordnance bureau of the Army during the war. Dr. Franklin's work on liquid ammonia as an electrolytic solvent is familiar to all chemists. In addition to his university work, he was in industrial work for a number of years, having had experience in the sugar industry and also in the gold mining industry. In the latter work he was stationed at Miramar, Costa Rica, in 1897.

Dr. Franklin was chosen from the four nominees for president of the Society who received the largest number of votes. The choice among these four was determined by a vote of the councilors of the society. The three other leading candidates were James F. Norris of Massachusetts Institute of Technology, Samuel S. Parr of the University of Illinois, and Charles L. Reece, of E. I. du Pont de Nemours & Co.

Canadian Atmospheric Nitrogen Plant Will Resume Operation

Plans are being formulated for the further development of an atmospheric nitrogen products industry in British Columbia. A plant was established four years ago on the site of the British Columbia Electric Railway Company's plant at Lake Buntzen by an American company which operated throughout 1920 and a part of 1921, using the surplus energy generated by the electric company. Operations are about to be resumed with a daily output of about five tons of sodium nitrate and nitric acid. The plant will operate twenty-four hours a day and employ thirty-five men for the present, but should plans materialize the industry will be developed on a large scale.

American Metric Association Plans Meeting in Cambridge

The annual meeting of the American Metric Association is to be held on Dec. 30, at Massachusetts Institute of Technology, Cambridge. United States and Canadian Government departments, industrial and commercial organizations and corporations interested in metrology are especially invited to have representatives present.

The addresses and discussions at all sessions will be confined chiefly to those actually engaged in commerce or industry. Those primarily interested in education, public welfare, and co-operation between nations, are regarded as natural allies in the metric movement.

The Decimal Association of London, working in England for decimal currency and metric weights and measures, has requested the co-operation of the American Metric Society in urging the abandonment of the British and American gallons and the adoption in their place of the international liter as their common unit of capacity.

The liter is less than the Imperial quart and greater than the American quart, and its adoption would thus—in effect—strike an average between the existing British and American practices.

Ask Fertilizer Man's Aid to Relieve Car Shortage

Efforts by Shippers to Sell Carload Lots and Deliver in Off Seasons Would Improve Conditions

A plea for the use of cars during other months than those of the late summer and fall has been made to the National Fertilizer Association by M. J. Gormley, the chairman of the car service division of the American Railway Association. It is a reply to the various complaints which have been lodged with his organization by numerous fertilizer manufacturers who have suffered from their inability to obtain enough cars. While the association is willing to admit that shippers have an important responsibility in obtaining the prompt release of cars, there is a feeling that the great losses entailed by the annual car shortage is so much greater than the relatively small loss resulting from cars being unemployed during certain months that some steps must be taken to increase the amount of equipment available when the freight movement is heaviest.

Mr. Gormley pointed out that from January, 1912, to November, 1922, the country has passed through 87 months of car surplus and 43 months of car shortage. Surplus cars ranged as high as 486,000 averaged monthly, with shortages of about 166,000 cars. During these periods only 64 per cent of the capacity of freight cars was utilized. Car loading reached its peak during the fall of 1920 and figures indicate that approximately 2,250,000 fewer cars would have been used during the year 1921 to handle the same amount of tonnage provided the cars had been as heavily loaded during the entire year of 1921 as they were during the last quarter of 1920. The loading per car of many commodities for the first 6 months of 1922 had declined under the 1921 basis, hence it is timely from both the standpoint of the carrier and the shipper to stress the necessity for greater effort in this regard.

Relief Measures

Directly related to the more efficient use of equipment and the spreading out of the distribution of the seasonal movement of commodities is the willingness and ability of the purchaser to place his orders for full carloads, not in fixed quantities as may be governed by set tariff minimums or trade units. Furthermore, the purchaser should be induced to place his orders in advance of his immediate necessities and wherever possible to carry a stock of the products which will allow the producer to make shipments during periods of the year when transportation facilities are least congested and when thousands of cars or locomotives are normally available to effect quicker dispatch.

New Italian Ambassador to Be Welcomed by Fellow Engineers

American engineers are planning a big reception to Prince Gelasio Caetani, Italian Ambassador to Washington, now on his way to this country. A dinner, at which engineers from all parts of the country will be present, will be given in honor of the new diplomat, himself an engineer, by the American Engineering Council of the Federated American Engineering Societies in Washington on the evening of Jan. 12.

"Joyfully returning to states which have been my second home," said a cable message from Prince Caetani to Colonel Arthur S. Dwight, member of the executive board of the American Engineering Council and president of the American Institute of Mining and Metallurgical Engineers. "Ready to devote myself to the good of both countries. I am looking forward with intense pleasure to meeting old friends at dinner kindly offered. Expect to arrive Dec. 20."

Personal

Ernest G. Jarvis, superintendent of foundries and rolling mills for the McNab & Harlin Mfg. Co., Paterson, N. J., has resigned, effective Jan. 1, 1923. Mr. Jarvis expects to take a much needed rest for a few months and about Jan. 15 will sail for a cruise of South and Central America. After his return he will resume his metallurgical activities in a consulting way.

Dr. Charles F. Kettering, president of the General Motors Research Corporation, addressed the Harvard Medical Society at the Harvard Club, New York, on Dec. 15, on the subject "An Engineer's Perspective of Modern Science."

Dr. Irving Langmuir gave a series of three lectures at the Carnegie Institute of Technology, Pittsburgh, Pa., Nov. 27, 28 and 29, on recent discoveries in electron emission and current control.

A. E. Marshall has resigned as president of Marshall Rieha, Inc., and will in future devote his attention solely to plant design, consultation and report work for the chemical industry. His office is at 3034 St. Paul St., Baltimore, Md.

David J. Price, engineer in charge of development work of the Bureau of Chemistry of the U. S. Department of Agriculture, recently in addressing the Safety Bureau of the Chamber of Commerce, Buffalo, N. Y., declared there is no such thing as a spontaneous explosion and called attention to the danger of dust explosions in various kinds of industrial plants and discussed the methods of prevention that have proved effective.

Dr. J. W. Reedy was recently elected chairman of the University of Illinois section of the American Chemical Society. Prof. A. M. Buswell was chosen vice-chairman, Dr. D. M. Engles secretary and Edith H. Nason treasurer.

Franklin H. Smith, former assistant secretary of the National Lumber Manufacturers' Association, has become associated with the U. S. Tariff Commission as chief of its Forest Products Division. Mr. Smith was for many years connected with the U. S. Forest Service.

Dr. Samuel Wesley Stratton was the guest of honor at a farewell reception at the Bureau of Standards on Thursday, Dec. 14. The program included a most elaborate display of interesting work of the bureau and a visit to a number of the industrial laboratories. Dr. Stratton was presented with a fine silver service from the members of the staff of the bureau.

Hugh S. Taylor has been promoted by the trustees of Princeton University to a full professorship in the department of chemistry, with the title of professor of physical chemistry.

Dr. John E. Teeple expects to sail for London on Jan. 2.

Stanley Woodward, formerly director of purchases for The Barrett Co. and W. B. Harris, formerly general sales manager of the same organization and later assistant to the president, have resigned. Together with T. M. Rianhard, formerly president of The Barrett Co., they expect to engage in the roofing business in Baltimore.

Market Conditions

In Chemical, Metallurgical and Allied Industries

Guessing About Credits

Most Business Failures Are Caused by Lack of Discretion on the Part of Selling Houses

It must be admitted that there is no substitute for good judgment in business, but the average business man can profitably spend a considerably larger share of his time in analyzing the problems of production and distribution. A phase of the latter subject which, according to a recent statement of the National Association of Credit Men, has not received the attention it deserves, has to do with credit matters. The association declares that in the field of credits there is too much guessing and too little critical investigation. In part, the statement is as follows:

"When conceding that a large proportion of commercial failures are accounted for by the indiscretions of the selling houses, then surely the thesis cannot be successfully contested that in credits too much is taken for granted and the surface is too frequently regarded as indicative of the entire situation.

"When serious wastes may happen—and they have happened with us frequently because of these defects—then it is high time for us to become economic observers, closer students of markets, with more individual ability to forecast the future and to appraise the real qualities of a credit risk.

"We cannot regard excessive bad debt losses without conceding that critical investigation was lacking.

"Waste is deplorable, especially when it need not happen, and we appeal to the commercial and credit workers of the nation to increase their powers of economic observation; to develop a critical ability that will insure a proper flow of commodities and a volume of credits that will liquidate with a small amount of loss."

Chemical Exports Holding Their Own

Total Shipments for 10 Months Valued at $87,901,236, Only One-Half Per Cent Less Than in 1921

Exports of chemicals and allied products for the 10-month period, January-October, 1922, compared with the corresponding period in 1921, indicate that chemicals are holding their own, according to C. Concannon, acting chief of the Chemical Division of the Department of Commerce. Total exports for the period were $87,901,236 in 1922, which is not quite one-half of one per cent less than in the corresponding 10 months of 1921.

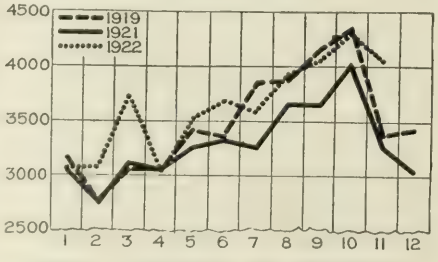
While the percentage of increases in certain classes in 1922 over 1921 are not as high as during the previous period, January-September, the percentage of decreases in others are lower. Of the sodium compounds exported, caustic soda showed a gain of 244 per cent; borax, 190 per cent; sodium silicate, 21 per cent; and soda bicarbonate, 11 per cent; while soda ash recorded a loss of 24 per cent. Sal soda decreased 15 per cent in value, but gained 3 per cent in quantity.

Of the other chemicals recording marked improvement, nitric acid was the most important, advancing over 120 per cent in value, from $18,906 (122,794 lb.) in 1921 to $41,863 (630,646 lb.) in 1922. Shipments of wood and denatured alcohol increased from 344,853 gal., valued at $400,056, to 1,028,181 gal., valued at $735,473; glycerine from 1,411,223 lb., valued at $231,698, to 2,594,808 lb., valued at $381,543; acetate of lime from 15,139,051 lb., valued at $331,960, to 24,653,025 lb., valued at $501,325; bleaching powder from 12,815,794 lb., valued at $363,589, to 33,188,418 lb., valued at $545,483, and copper sulphate from 3,132,306 lb., valued at $196,382, to 4,675,115 lb., valued at $224,647. Benzol, carbolic acid and sulphuric acid all showed decreases in 1922.

A Year of Business Expansion

Freight Car Loadings During 1922 Clearly Indicate the Improvement Over 1920 and 1921

Freight car loadings represent distribution of commodities and therefore constitute an accurate index of the movement of general business. If the total monthly loadings of revenue freight are compared for the years



TOTAL LOADINGS OF REVENUE FREIGHT BY MONTHS, 1919, 1921, AND 1922
(Unit: 1,000 cars)

"Chem. & Met." Weighted Index of Chemical Prices

Base — 100 for 1913-14

This week	168.35
Last week	168.73
December, 1921	145
December, 1920	245
April, 1918 (high)	286
April, 1921 (low)	140

The principal changes reported among the index commodities were for cottonseed and linseed oils. The former was ¼c. per lb. lower than last week, while linseed oil showed a gain of 3c. per gal. Ammonium sulphate showed a net gain of 5c. on the 100 lb.

1919, 1921 and 1922, some interesting information is disclosed. In the first place, it is scarcely necessary to show that 1921 was a year of depression. But it is interesting to note that except for the one month of April (the first of the coal strike) loadings during the current year have exceeded those of 1921 and have very closely approximated the records of 1919. The peak in both cases was reached about the middle of October, but the seasonal drop during November has been less abrupt during 1922 than in 1919.

This indisputable evidence of business expansion is shown graphically in the accompanying chart, which has been copyrighted by the Harvard University Committee on Economic Research.

Alcohol Statistics for 1922

Annual Report of Internal Revenue Commissioner Reviews Production and Distribution of Alcohol

The industrial alcohol and chemical division of the Bureau of Internal Revenue has recently prepared an interesting summary of its operations during the year ended June 30, 1922. At the close of the last fiscal year, it reports, there were seventy-three industrial alcohol plants, seventy-eight bonded warehouses and seventy-four denaturing plants qualified to operate for the production, storage and denaturation of alcohol, respectively, under Title III of the national prohibition act. During the year nine industrial alcohol plants, ten bonded warehouses and twelve denaturing plants were established, while six industrial alcohol plants, eight bonded warehouses and three denaturing plants were discontinued, resulting in a comparatively small net increase over the number qualified on June 30, 1921. For the production of distilled spirits for nonbeverage purposes, other than alcohol, there were operated during the year

two grain distilleries, two rum distilleries and thirty-three fruit distilleries.

Distilled Spirits — During the fiscal year ended June 30, 1922, there was produced 79,906,101.51 proof gallons of alcohol, a decrease of 5,162,674.82 proof gallons compared with the quantity produced during the preceding fiscal year.

There was withdrawn from warehouse on payment of tax 16,363,301.85 proof gallons of alcohol, and there was withdrawn for tax-free purposes, including withdrawals for denaturation, for export and for use of the United States hospitals, laboratories, colleges and other educational institutions, a total of 63,147,767.22 proof gallons of alcohol.

There was withdrawn, tax paid, from distillery, general and special bonded warehouses 2,724,363.4 taxable gallons of distilled spirits (including brandy) other than alcohol, a decrease of 6,352,782.1 gal. compared with the quantity withdrawn tax paid during the preceding year.

Denatured Alcohol — The number of bonded manufacturers using specially denatured alcohol at the end of the fiscal year 1922 was 3,287, compared with 1,761 such manufacturers at the end of the fiscal year 1921. The increase of 1.526 was due to the qualification of many permittees heretofore using pure alcohol. During the same period of time sixty-seven permits to use specially denatured alcohol were revoked by the department.

During the fiscal year 1922 there was withdrawn from bond, free of tax, for denaturation 59,549,919.6 proof gallons of alcohol and rum, against 38,812,138.7 proof gallons withdrawn for this purpose during the previous year.

There was 33,345,747.91 wine gallons of denatured alcohol produced during the past fiscal year, of which 16,193,523.60 wine gallons was completely denatured and 17,152,224.31 wine gallons was specially denatured, compared with 22,388,824.92 wine gallons of denatured alcohol produced during the previous fiscal year, of which 12,293,595.02 wine gallons was completely denatured and 9,996,229.90 wine gallons was specially denatured.

Less Oleomargarine in 1922

In order to exact the internal revenue tax on oleomargarine it is necessary for the government to keep an accurate record of production and consumption of this commodity. The Commissioner of Internal Revenue in his annual report for the fiscal year 1922 has presented some interesting statistics on this industry.

During the year ended June 30, 1922, there were seventy-two oleomargarine factories in operation. Nine factories closed during the year, leaving sixty-three in business on June 30, 1922. The seventy-two factories produced 6,603,981 lb. of colored and 184,346,392 lb. of uncolored oleomargarine, compared with 11,600,319 lb. of colored and 269,481,195 lb. of uncolored oleomargarine in the fiscal year 1921, a decrease of 43.1 and 31.6 per cent, respectively.

Babson's Views on Linseed Oil

The Babson statistical organization has recently been advising its clients against laying in heavy stocks of linseed oil. Apparently precautions should be taken to insure adequate supplies for the next few months, but it is not considered advisable to build up any considerable inventories. The *Buyer's Bulletin* for Dec. 12 contains the following statement: "We do not advocate heavy inventories of linseed oil, because supplies of this commodity are undoubtedly adequate to meet the prospective demand. The domestic flaxseed crop is the largest since 1918, estimated at 12,101,000 bushels—a marked increase over the 1921 crop of only 8,112,000 bushels. Then again Argentina is growing a tremendous amount of this commodity. Recent estimates place this season's crop at 60,000,000 bushels, as against only 30,000 000 last year. It is true that there is a tariff on the seed, but it is not sufficiently high to keep foreign seed out of the country. Imports of linseed oil prior to the tariff were extremely heavy, being six times as large as those of last year. The probable demand is fairly good, but we feel that it is discounted by current prices, which are 50 per cent above pre-war levels."

Cost Studies a Legitimate Activity of Trade Associations

Trade associations or groups interested in cost accounting may meet solely for the purpose of the study of costs, the detection of errors and the improvements of their methods without contravention of law, in the opinion of Commissioner Nelson B. Gaskill, of the Federal Trade Commission.

"I have previously expressed my firm belief," said Commissioner Gaskill, "that cost accounting is a legitimate trade association activity, and subsequent consideration has merely strengthened this conviction. Collective analytical study of the results of cost accounting furnishes an invaluable supplement to the individual cost accounting work. Comparison of results, analysis of results and the study and discussion of these results lead to the improvement of methods and the increase of efficiency. To prohibit collective study of costs for the purpose of their analysis, the detection of errors, and the improvement of methods, is to shackle educative progress.

"Of course the legal situation is confused by reason of the decisions in the hardwood lumber case and the linseed oil case, and it will be some time before this confusion will be cleared by any additional authoritative decisions. Trade associations must therefore determine as accurately as they can the legitimate field of proper endeavor and having so taken counsel, should, without hesitation, resting upon their legal advice and the clear consciousness of the propriety of their efforts, proceed without fear, willingly inviting the test of the courts' consideration of their conduct."

Solvents at Higher Levels in New York Market

Formaldehyde, Arsenic and Methanol Are Also Firmly Maintaining Recent Advances

Manufacturers of fusel oil, ethyl acetate and amyl acetate have announced a new advance in prices. The demand has become more pronounced of late and sellers have not been eager to book round lot business. The new price of fusel oil represents the high mark for 1922 and shows a net advance of $1 per gal. since January. Although producers of acetic acid, acetone and calcium acetate have not yet raised their prices, it is generally agreed in the trade that some revisions will be announced before the turn of the new year. Resale lots of formaldehyde are being quickly disposed of and the market is rapidly coming into the hands of the producer. Arsenic still continues along very steady lines, with demand very strong from the insecticide and calcium arsenate manufacturers. Manufacturers report a completely sold up condition at the works. Methanol retained its recent advance.

The approaching holidays seemed to have a quieting effect on the general list and aside from the rise in solvents the market showed no special features. Carbonate of potash was somewhat weaker and prices were fractionally lower. Lead arsenate, on the other hand, showed a very strong tendency and prices recorded an advance of 6c. per lb. during the interval. The alkali market continued along moderately active lines, with domestic consumers showing considerable interest in future developments. Contracts over 1923 have gone through in far better volume than a year ago and producers are quite satisfied with the general trend.

High Spots in the Market

Arsenic—Producers are not quoting and second hands report a very light supply on the spot market. Small quantities were recorded around 15c. per lb. Future shipments are held at 14½@14¾c. per lb., N. Y.

Bleaching Powder — Manufacturers reported a strong demand from consumers for contracts over 1923. Carload lots were quoted at $1.90 per 100 lb., f.o.b. works. Spot goods were held around $2.25 per 100 lb. in large drums.

Barium Chloride—Imported material was somewhat lower, due to the lack of consuming interest and prices were quoted down to $90@$95 per ton. Domestic factors quoted goods at the works at $95 per ton.

Ethyl Acetate—Leading producers announced a new price advance due to increased production costs. New prices range from 80@85c. per gallon.

Formaldehyde—Second hands were not eager to quote at lower than producers' prices and the market is very strong. January shipments were quoted for carloads at 16c. per lb., and less than carloads at 16½c. per lb. Spot goods were quoted around 15¾@16c. per pound.

Fusel Oil—Producers reported another increase in prices. Spot material is being held around $3.55 per gal. This represents the highest level of the year and shows a gain of $1.05 per gal. since January, 1922.

Lead Arsenate—Manufacturers announced a sharp advance due to the increased production costs and heavy demand from consuming quarters. Late figures ranged around 20c. per lb., showing an advance of 6c. per lb. within an interval of one week.

Prussiate of Potash—Yellow material showed some signs of weakness and prices were fractionally lower on spot. The general range was 38½@39c. per lb. Red prussiate showed no new features of interest and prices remained around 92@95c. per lb.

Soda Ash—Export business was quiet during the past week, but domestic consumers were buying for contract requirements. Spot material in bags, carload lots, held around $1.75 per 100 lb. Contracts for over 1923 were being made at $1.20 per 100 lb., basis 48 per cent, f.o.b. works, carload lots.

Good Prospects for 1923 in Chicago Market

Current Business, However, Slackens Off for Holidays

CHICAGO, Ill., Dec. 22, 1922.

The outlook for next year's business in the Chicago market was reported as exceptionally good and a general feeling of optimism prevailed throughout the trade. Due to the approaching holiday season and the inventory period, however, the chemical market has been very quiet. No business of any consequence was reported from most quarters, but the condition was thought to be only temporary. Prices held firm, as it was quite evident that lower prices would not stimulate the market.

CAUSTIC SODA FIRMER

Firm prices were the feature of the *caustic soda* market during the past 2 weeks and a fair amount of spot business was reported. The solid 76 per cent material was quoted in ton lots at $3.50 per 100 lb. and the ground in like lots of a similar quality at $4.25. *Caustic potash* was in rather poor demand, with only supplies of the foreign material available. The general quotation for small or moderate lots of the 88-92 per cent material was 7½c. per lb. *Soda ash* was unchanged in price and a satisfactory volume of business was reported at $2.25 per 100 lb. for material in cooperage.

Alums were quiet, with no change reported in the list. Foreign *potash alum* was quoted at 4½@5c. per lb. for the lumps and 5½@6c. for the powder. *Sal ammoniac* was firm at 8c. per lb. for either the domestic or foreign article. *Ammonium carbonate* was in light supply on spot and what was available was held for 11@12c. per lb. *Barium chloride* was in fair request and small lots were quoted at $110 per ton. *Barium carbonate* was quiet, with only odd lots offered at $90@$95 per ton. *White arsenic* was practically off of the market, with only a few kegs available at 16@18c. per lb. *Copper sulphate* continued to move in a fair way and the price was firm at 6c. per lb. for small or moderate lots. *Carbon bisulphide* was in fair demand, but spot supplies were still light. Single drums were quoted at 7@7½c. per lb. *Carbon tetrachloride* was firm after the recent advance and 10½c. per lb. for large drums was the generally quoted price. Formaldehyde was advanced in price again due to the higher level on *methanol*. The new price was 17c. per lb. for less than 5-bbl. lots and dealers reported a fair volume of business at that figure. *Glycerine* was firm at 18½c. per lb. for the c.p. material in drums, but the movement was not very heavy.

Cyanide of potash was in poor demand, but due to the scarcity of supplies the price of 55c. per lb. was maintained. *Red prussiate of potash* was still very scarce, with only small lots available at 95c.@$1 per lb. *Permanganate of potash* was slightly easier and U.S.P. crystals were quoted for immediate delivery at 17½c. per pound.

LINSEED OIL AND TURPENTINE

Linseed oil was very quiet, with dealers reporting little or no business. The boiled oil is quoted at 93c. per gal. in single-drum lots and the raw in similar lots at 91c.

Like linseed oil, *turpentine* was very quiet, with practically nothing moving. The quotation is $1.46 per gal. for single-drum lots.

Iron and Steel Stronger Than Expected

The Usual Slump for Inventory and Holidays Has Apparently Been Avoided

PITTSBURGH, Dec. 22, 1922.

The steel market is proving stronger and more active, at this time of year, than was commonly expected. It is habitual with the market to be quiet in December, but there is on the whole a very fair turnover. As to production, in turn, buyers usually prefer shipments to be light in December, to relieve inventory, but in general steel production is maintained and of course the product is all being shipped.

FROM SELLERS' TO BUYERS' MARKET

Approximately from April 1 to Oct. 1 there was a sellers' market in steel products, at first with merely a slight stiffening in prices and afterward, as high fuel costs were fastened upon the industry, with some fairly sharp advances. In the latter part of the period deliveries were very difficult to arrange in many cases, and delivery premiums developed in several lines, including bars, shapes, plates and sheets. All such delivery premiums disappeared some time ago. Of late there has been a buyers' market in place of a sellers' market. The change has altered the aspect of market affairs so that the market has appeared quieter and with less underlying strength than has really been the case. The feature of there being a buyers' market applies to deliveries, it being possible to arrange without difficulty almost any delivery desired, except in wire products and pipe in which lines the mills are still far in arrears. There being a buyers' market does not, however, apply to prices, for steel prices are well maintained. There had been no expectation that prices of pipe, wire products, sheets or tin plate would decline, but there were many predictions, a month and more ago, that the end of the year would see a lower market on bars, shapes and plates, perhaps a 1.75c. price. The outcome, however, is that these heavy rolled products are still quotable steady at 2c. Concessions may be made occasionally, but only in exceptional circumstances, and probably to no greater extent than they were being made a month and more ago. Some large interests occupy the strategic position of having no regular or official price, so that they are free to meet price cuts at any moment, and this situation has tended to discourage other mills from cutting.

COKE AND PIG IRON PRICES

Since the buying movement in foundry iron, whereby a fairly large tonnage was put under cover for first quarter, the market has been quiet and furnaces have advanced prices. In the valley market the price is $25 furnace, and all makers are now squarely on a basis of $26 valley. Basic iron did not move to any extent, for the double reason that consumers are not so sure of their requirements in first quarter as are the foundries that bought—largely radiator and sanitary ware makers—and they have more sources from which to draw, since many if not the majority of steel interests are willing to sell basic iron. Few of them can make foundry iron to advantage. Basic has sold in two or three instances at $24.25 valley, but all makers now seem to be firm at $24.50, some of them having an asking price of $25. Bessemer has been moving in carload lots at $27.50 valley.

Connellsville coke has had a complete upset, advancing the market in the neighborhood of $3 a ton and putting it out of the reckoning with blast furnaces. The occasion was a sudden rush of buying by Eastern distributors of domestic fuel. A few thousand of tons difference in the relation between demand and supply in a week has had distinct results in making market prices. Late last week buying orders from the East appeared, in lots of 25 or 50 carloads at a time. All floating supplies were absorbed, and some prospective production as well. Early last week furnace coke was a trifle weak at $6.50, with free offerings, while this week $9 has been paid by Eastern buyers. The furnaces are nonplussed, as they were about to negotiate for first quarter supplies and expected to buy at less than the recently going spot market, $6.50@$7.

General Chemicals

Current Wholesale Prices in New York Market

		Carlots F.o.b. N.Y.	Less Carlots F.o.b. N.Y.

Picric	lb.	.20 – .22	.23 – .27
Pyrogallic, resublimed	lb.	—	1.55 – 1.65
Sulphuric, 60 deg., tank cars	ton	9.00 – 10.00	—
Sulphuric, 60 deg., drums	ton	12.00 – 14.00	—
Sulphuric, 66 deg., tank cars	ton	14.50 – 15.00	—
Sulphuric, 66 deg., drums	ton	19.00 – 20.00	20.50 – 21.00
Sulphuric, 66 deg., carboys	ton	—	—
Sulphuric, fuming, 20 per cent (oleum) tank cars	ton	19.00 – 20.00	—
Sulphuric, fuming, 20 per cent (oleum) drums	ton	22.00 – 22.50	23.00 – 24.00
Sulphuric, fuming, 20 per cent (oleum) carboys	ton	31.00 – 32.00	33.00 – 34.00
Tannic, U. S. P.	lb.	—	.70 – .75
Tannic (tech.)	lb.	.40 – .45	.46 – .50
Tartaric, imported crystals	lb.	—	.30½ – .31
Tartaric acid, imported, powdered	lb.	—	.31 – .32
Tartaric acid, domestic	lb.	—	— .32
Tungstic, per lb. of WO	lb.	—	1.20 – 1.30
Alcohol, ethyl (Cologne spirit)	gal.	—	4.75 – 4.95
Alcohol, methyl (see methanol)			
Alcohol, denatured, 188 proof No. 1	gal.	—	.39 – .41
Alcohol, denatured, 188 proof No. 5	gal.	—	.38 – .40
Alum, ammonia, lump	lb.	.03½ – .03¾	.04 – .04¼
Alum, potash, lump	lb.	.03¼ – .03½	.03½ – .04
Alum, chrome lump	lb.	.05 – .05½	.05½ – .06
Aluminum sulphate, commercial	100 lb.	1.50 – 1.65	1.70 – 2.25
Aluminum sulphate, iron free	lb.	.02½ – .02¾	.03 – .03¼
Aqua ammonia, 26 deg., drums (750 lb.)	lb.	.06¾ – .07¼	.07½ – .08
Ammonia, anhydrous, cyl. (100-150 lb.)	lb.	.30 – .30½	.30½ – .31
Ammonium carbonate, powder	lb.	.09 – .09½	.09½ – .10
Ammonium nitrate	lb.	.07¾ – .07½	.07½ – .08
Amylacetate tech	gal.	—	2.80 – 3.05
Arsenic, white, powdered	lb.	.15½ – .16	.16½ – .16½
Arsenic, red, powdered	lb.	.13½ – .14	.14½ – .15
Barium carbonate	ton	75.00 – 77.00	78.00 – 80.00
Barium chloride	ton	90.00 – 92.00	93.00 – 100.00
Barium dioxide (peroxide)	lb.	.18 – .18½	.19 – .20
Barium nitrate		.08½ – .08¾	.09 – .09½
Barium sulphate (precip.) (blanc fixe)	lb.	.04 – .04½	.04½ – .04¾
Blanc fixe, dry	lb.	.04 – .04½	—
Blanc fixe, pulp	ton	45.00 – 55.00	—
Bleaching powder	100 lb.	2.25 – 2.35	2.40 – 3.50
Blue vitriol (see copper sulphate)			
Borax	lb.	.05½ – .05¾	.06 – .06¾
Brimstone (see sulphur, roll)			
Bromine	lb.	.27 – .28	.28½ – .35
Calcium acetate	100 lb.	3.50 – 3.60	3.65 – 3.75
Calcium carbide	lb.	.04½ – .04¾	.05 – .05½
Calcium chloride, fused, lump	ton	22.00 – 23.00	23.50 – 27.00
Calcium chloride, granulated	lb.	.01½ – .01¾	.02 – .02½
Calcium peroxide	lb.	—	1.40 – 1.50
Calcium phosphate, tribasic	lb.	—	.15 – .16
Camphor	lb.	—	.95 – .96
Carbon bisulphide	lb.	.07 – .07½	.07½ – .08
Carbon tetrachloride, drums	lb.	.10 – .10½	.10½ – .12
Carbonyl chloride, (phosgene)	lb.	—	.60 – .75
Caustic potash (see potassium hydroxide)			
Caustic soda (see sodium hydroxide)			
Chalk, precip.—domestic, light	lb.	.04½ – .04¾	—
Chalk, precip.—domestic, heavy	lb.	.03½ – .03¾	—
Chalk, precip.—imported, light	lb.	.04½ – .05	—
Chlorine, gas, liquid-cylinders (100 lb.)	lb.	.05¾ – .06	.06¼ – .06½
Chloroform	lb.	—	.35 – .38
Cobalt oxide	lb.	—	2.10 – 2.40
Copperas	ton	25.00 – 27.00	27.50 – 30.00
Copper carbonate, green precipitate	lb.	.20 – .20½	.21 – .22
Copper cyanide	lb.	—	.50 – .55
Copper sulphate, crystals	100 lb.	6.00 – 6.25	6.30 – 6.50
Cream of tartar	lb.	—	.25½ – .26
Epsom salt (see magnesium sulphate)			
Ether, U.S.P. 100 drums	lb.	—	.13 – .15
Ethyl acetate com. 85%	gal.	—	—
Ethyl acetate, pure (acetic ether, 98% to 100%)	gal.	—	.90 – .95
Formaldehyde, 40 per cent	lb.	.15½ – .16	.16¼ – .16½
Fullers earth, f.o.b. mines	net ton	16.00 – 17.00	—
Fullers earth—imported powdered	net ton	30.00 – 32.00	—
Fuse oil, ref	gal.	—	3.55 – 4.05
Fusel oil, crude	gal.	—	2.30 – 2.40
Glauber's salt (see sodium sulphate)			
Glycerine, c.p. drums extra	lb.	—	.18¼ – .18½
Iodine, resublimed	lb.	—	4.50 – 4.60
Iron oxide, red	lb.	—	.12 – .18
Lead acetate, white crystals	lb.	—	.12 – .12½
Lead arsenate, powd	lb.	.20 – .20½	.20½ – .21
Lead nitrate	lb.	—	.18 – .22
Litharge	lb.	.09¼ – .09½	.09½ – .10
Magnesium carbonate, technical	lb.	.07 – .07½	.07¾ – .08
Magnesium sulphate, U.S.P.	100 lb.	2.50 – 2.65	2.70 – 3.50
Magnesium sulphate, technical	100 lb.	—	1.20 – 1.85
Methanol, 95%, bbls	gal.	—	1.23 – 1.25
Methanol, 97%, bbls	gal.	—	1.25 – 1.27
Nickel salt, double	lb.	—	$0.10 – $0.10½
Nickel salt, single	lb.	—	.11 – .11½
Phogene (see carbonyl chloride)			
Phosphorus, red	lb.	—	.35 – .40
Phosphorus, yellow	lb.	—	.30 – .35½
Potassium bichromate	lb.	$0.09½ – .10	.10½ – .10½
Potassium bromide, granular	lb.	—	.17 – .23
Potassium carbonate, U. S. P.	lb.	.10 – .10½	.11 – .15
Potassium carbonate, 80-85%	lb.	.05½ – .05¾	.06 – .06½
Potassium chlorate, powdered and crystals	lb.	.07¾ – .08	.08¼ – .09
Potassium cyanide	lb.	—	47 – .50
Potassium hydroxide (caustic potash)	100 lb.	6.25 – 6.50	6 60 – 6 75
Potassium iodide	lb.	—	3.55 – 3.65
Potassium nitrate	lb.	.06½ – .06¾	.07 – .08
Potassium permanganate	lb.	.15 – .15½	.16 – .17
Potassium prussiate, red	lb.	—	.92 – .95
Potassium prussiate, yellow	lb.	.38½ – .39	.39¼ – .39½
Rochelle salts (see sodium potas tartrate)			
Salammoniac, white, granular	lb.	.06½ – .06¾	.07 – .07½
Salammoniac, gray, granular	lb.	.08 – .08¾	.08½ – .08½
Salsoda	100 lb.	1.20 – 1.40	1.45 – 1.60
Salt cake (bulk)	ton	25.00 – 27.00	—
Soda ash, light, 58 per cent flat, bags, contract	100 lb.	1.60 – 1.67	2.00 – 2.25
Soda ash, light, 58 per cent flat, bags, resale	100 lb.	1.75 – 1.80	1.85 – 2 35
Soda ash, dense, in bags, resale	100 lb.	1.85 – 1.90	1.95 – 2.40
Sodium acetate	lb.	.07½ – .07¾	.08 – .08½
Sodium bicarbonate	100 lb.	1.75 – 1.85	1.90 – 2.30
Sodium bichromate	lb.	.07½ – .07¾	.08 – .08¼
Sodium bisulphate (nitre cake)	ton	4.50 – 4.60	4.65 – 5.50
Sodium bisulphite powdered, U.S.P.	lb.	.04¼ – .04½	.04½ – .05½
Sodium chlorate	lb.	.06½ – .07	.07½ – .07½
Sodium chloride	long ton	12 00 – 13 00	—
Sodium cyanide	lb.	.19½ – .21	.21½ – .25
Sodium fluoride	lb.	.09 – .09¼	.09½ – .10
Sodium hydroxide (caustic soda) solid, 76 per cent flat, drums, contract	100 lb.	3.35 – 3.40	3.75 – 4.00
Sodium hydroxide (caustic soda) solid, 76% flat, drums, resale	100 lb.	3.50 – 3.60	3.65 – 4.00
Sodium hydroxide (caustic soda), ground and flake, contracts	100 lb.	3.80 – 3.90	4.25 – 4.40
Sodium hydroxide (caustic soda) ground and flake, resale	100 lb.	4.00 – 4.15	4.40 – 4.60
Sodium hyposulphite	lb.	.03 – .03¼	.03½ – .04
Sodium nitrite	lb.	.08¾ – .09	.09½ – .09½
Sodium peroxide, powdered	lb.	.28 – .30	.31 – .35
Sodium phosphate, dibasic	lb.	.03½ – .04	.04½ – .04½
Sodium potassium tartrate (Rochelle salts)	lb.	—	.18 – .21
Sodium prussiate, yellow	lb.	.20½ – .21	.21½ – .21½
Sodium silicate, (40 deg. in drums)	100 lb.	1.25 – 1.30	1.35 – 1.50
Sodium silicate, (60 deg. in drums)	100 lb.	2.25 – 2.40	2.45 – 2.75
Sodium sulphate, crystals (glaubers salt)	100 lbs.	.85 – .95	1.00 – 1.40
Sodium sulphide, fused, 60-62 per cent (conc.)	lb.	.04½ – .04¾	.05 – .05½
Sodium sulphite, crystals	lb.	.03½ – .03⅝	.03½ – .04½
Strontium nitrate, powdered	lb.	.09½ – .10	.10½ – .12
Sulphur chloride, yellow	lb.	.04½ – .05	.05½ – .06
Sulphur, crude	ton	18.00 – 20.00	—
Sulphur dioxide, liquid, cylinders extra	lb.	.08 – .08½	.09 – .10
Sulphur (sublimed), flour	100 lb.	—	2.50 – 3.15
Sulphur, roll (brimstone)	100 lb.	2.15 – 2.20	2.25 – 2.75
Talc—imported	ton	30 00 – 40 00	—
Talc—domestic powdered	ton	18.00 – 25.00	—
Tin bichloride	lb.	.10½ – .10¾	.11 – .11½
Tin oxide	lb.	—	.43 – .45
Zinc carbonate	lb.	.14 – .14½	.14¾ – .15½
Zinc chloride, gran	lb.	.07 – .07½	.07¾ – .08
Zinc cyanide	lb.	.42 – .44	.45 – .47
Zinc oxide, XX	lb.	.07½ – .08	.08¼ – .08½
Zinc sulphate	100 lb.	2.75 – 3.00	3.05 – 3.30

Coal-Tar Products

NOTE—These prices are for original packages in large quantities f.o.b. N.Y.:

Alpha-naphthol, crude	lb.	$0.95 — $1.00
Alpha-naphthol, refined	lb.	1.05 — 1.10
Alpha-naphthylamine	lb.	.28 — .30
Aniline oil, drums extra	lb.	.16½ — .17
Aniline salts	lb.	.24 — .25
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Anthracene, 80%, imported in drums, duty paid	lb.	.65 — .70
Benzaldehyde U S P	lb.	1.35 — 1.40
Benzene, pure, water-white, in drums (100 gal.)	gal.	.30 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.28 — .32
Benzene, 90%, in drums, resale	gal.	.37 — .40
Benzidine, base	lb.	.85 — .90
Benzidine sulphate	lb	.75 — .80
Benzoic acid, U.S.P.	lb.	.72 — .75
Benzoate of soda, U.S.P.	lb.	.57 — .65
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.55 — .60
Beta-naphthol, tech	lb.	.25 — .26
Beta-naphthyla mine, technical	lb.	1.00 — 1.25
Carbazol	lb.	.75 — .90
Cresol, U. S. P., in drums (100 lb.)	lb.	.14 — .20
Ortho-cresol, in drums (100 lb.)	lb.	.18 — .22
Cresylic acid, 97–99%, straw color, in drums	gal.	.60 — .65
Cresylic acid, 95-97%, dark, in drums	gal.	.55 — .58
Cresylic acid, 97%, resale	gal.	1.00 — 1 05
Dichlorbenzene	lb.	.07 — .09
Diethylaniline	lb.	.50 — .60
Dimethylaniline	lb.	.39 — .41
Dinitrobenzene	lb.	.20 — .22
Dinitroclorbenzene	lb.	.22 — .23
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.34 — .36
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.25 — .30
Diphenylamine	lb.	.54 — .56
H-acid	lb.	.75 — .80
Meta-phenylenediamine	lb.	.95 — 1.00
Monochlorbenzene	lb.	.08 — .10
Monoethylaniline	lb.	.95 — 1.10
Naphthalene crushed, in bbls	lb.	.05½ — .06
Naphthalene, flake	lb.	.06 — .06½

Naphthalene, balls	lb.	$0.06½ —	$0.07
Naphthionate of soda	lb.	.58 —	.65
Naphthionic acid, crude	lb.	.60 —	.65
Nitrobenzene	lb.	.10 —	.12
Nitro-naphthalene	lb.	.30 —	.35
Nitro-toluene	lb.	.15 —	.17
N-W acid	lb.	1.20 —	1.30
Ortho-amidophenol	lb.	2.25 —	2.30
Ortho-dichlor-benzene	lb.	.17 —	.20
Ortho-nitro-phenol	lb.	.85 —	.90
Ortho-nitro-toluene	lb.	.12½ —	.14
Ortho-toluidine	lb.	.14 —	.16
Para-amidophenol, base	lb.	1.15 —	1.20
Para-amidophenol, HCl	lb.	1.20 —	1.25
Para-dichlorbenzene	lb.	.17 —	.20
Paranitroaniline	lb.	.75 —	.80
Para-nitrotoluene	lb.	.55 —	.65
Para-phenylenediamine	lb.	1.50 —	1.55
Para-toluidine	lb.	.85 —	.90½
Phthalic anhydride	lb.	.40 —	.50
Phenol, U. S. P., drums	lb.	.34 —	.35
Pyridine, domestic	gal.	1.60 —	1.75
Pyridine, imported	gal.	1.40 —	1.60
Resorcinol, technical	lb.	1.50 —	1.55
Resorcinol, pure	lb.	2.00 —	2.10
R-salt	lb.	.55 —	.60
Salicylic acid, tech., in bbls	lb.	.35 —	.37
Salicylic acid, U. S. P	lb.	.40 —	.42
Solvent naphtha, water-white, in drums, 100 gal	gal	.37 —	.40
Solvent naphtha, crude, heavy, in drums, 100 gal	gal.	.22 —	.24
Sulphanilic acid, crude	lb.	.20 —	.22
Tolidine	lb.	1.20 —	1.30
Toluidine, mixed	lb.	.30 —	.35
Toluene, in tank cars	gal.	.35 —	.37
Toluene, in drums	gal.	.40 —	.43
Xylidines, drums, 100 gal	lb.	.40 —	.45
Xylene, pure, in drums	gal.	.45 —	.50
Xylene, pure, in tank cars	gal.	.45 —	....
Xylene, commercial, in drums, 100 gal	gal.	40 —	.42
Xylene, commercial, in tank cars	gal.	30 —	....

Waxes

Prices based on original packages in large quantities f.o.b. N.Y.

Bayberry Wax	lb.	$0.28 —	$0.30
Beeswax, refined, dark	lb.	.30 —	.32
Beeswax, refined, light	lb.	.34 —	.35
Beeswax, pure white	lb.	.39 —	.40
Candellila, wax	lb.	.34 —	.35
Carnauba, No. 1	lb.	.39 —	.40
Carnauba, No. 2, North Country	lb.	.23 —	.24
Carnauba, No. 3, North Country	lb.	.17½ —	.18
Japan	lb.	.15 —	.15½
Montan, crude	lb.	.03½ —	.04
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.04 —	.04¾
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.02½ —	.02¾
Paraffine waxes, refined, 118-120 m.p.	lb.	.03½ —	.03½
Paraffine waxes, refined, 125 m.p.	lb.	.03¾ —	.03¾
Paraffine waxes, refined, 128-130 m.p.	lb.	.04 —	.04¾
Paraffine waxes, refined, 133-135 m.p.	lb.	.04½ —	.04¾
Paraffine waxes, refined, 135-137 m.p.	lb	.05 —	.05¼
Stearic acid, single pressed	lb.	.09 —	.09¾
Stearic acid, double pressed	lb.	.09½ —	.09¾
Stearic acid, triple pressed	lb.	.10 —	.10½

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl	280 lb.	$6.25 —	....
Rosin E-I	280 lb.	6.35 —	....
Rosin K-N	280 lb.	6.45 —	$7.00
Rosin W. G.-W. W	280 lb.	7.75 —	8.25
Wood rosin, bbl	280 lb.	6.25 —	....
Spirits of turpentine	gal.	1.39 —	1.40
Wood turpentine, steam dist	gal.	1.35 —	....
Wood turpentine, dest. dist	gal.	1.25 —	....
Pine tar pitch, bbl	200 lb.	..... —	6.00
Tar, kiln burned, bbl. (500 lb.)	bbl.	..... —	12.50
Retort tar, bbl	500 lb.	..... —	11.00
Rosin oil, first run	gal.	.43 —	....
Rosin oil, second run	gal.	.51 —	....
Rosin oil, third run	gal.	.53 —	....
Pine oil, steam dist., sp.gr., 0.930-0.940	gal.		.90
Pine oil, pure, dest. dist	gal.		.85
Pine tar oil, ref., sp.gr. 1.025-1.035	gal.		.46
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla	gal.		.35
Pine tar oil, double ref., sp.gr. 0.965-0.990	gal.		.75
Pine tar, ref., thin, sp.gr., 1.080-1.960	gal.		.25
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990	gal.		.25
Pine wood creosote, ref	gal.		.52

Fertilizers

Ammonium sulphate, f.a.s., N. Y., double bags	100 lb.	3.65 —	3.75
Blood, dried, f.o.b., N. Y	unit	4.60 —	
Bone, 3 and 50, ground, raw	ton	42.00 —	44.00
Fish scrap, dom., dried, f.o.b. works	unit	3.10 —	3.20
Nitrate of soda	100 lb.	2.55 —	2.60
Tankage, high grade, f.o.b. Chicago	unit	4.65 —	4.75
Phosphate rock, f.o.b. mines, Florida pebble, 68-72%	ton	3.50 —	4.00
Tennessee, 78-80%	ton	7.00 —	8.00
Potassium muriate, 80%	ton	35.75 —	38.50
Potassium sulphate	unit	1.00 —	....

Crude Rubber

Para—Upriver fine	lb.	$0.25½ —	.25½
Upriver coarse	lb.	.17½ —	.17½
Upriver caucho ball	lb.	20½ —	.20½
Plantation—First latex crepe	lb.	.27½ —	.27½
Ribbed smoked sheets	lb.	.27½ —	.27½
Brown crepe, thin, clean	lb.	.23 —	.23½
Amber crepe No. 1	lb.	.23 —	.23½

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls	lb.	$0.12 —	$0.12½
Castor oil, AA, in bbls	lb.	.12½ —	.13
China wood oil, in bbls	lb.	.12½ —	.12½
Coconut oil, Ceylon grade, in bbls	lb.	.08⅝ —	.08¾
Coconut oil, Cochin grade, in bbls	lb.	.09 —	.09½
Corn oil, crude, in bbls	lb.	.10½ —	.10¾
Cottonseed oil, crude (f. o. b. mill)	lb.	.08½ —	....
Cottonseed oil, summer yellow	lb.	.10 —	.10½
Cottonseed oil, winter yellow	lb.	.11 —	.11½
Linseed oil, raw, car lots (domestic) bbls	gal.	.90 —	.91
Linseed oil, raw, tank cars (domestic)	gal.	.86 —	.87
Linseed oil, boiled, in 5-bbl lots (domestic)	gal.	.92 —	.93
Olive oil, denatured	gal.	1.05 —	1.12
Palm, Lagos	lb.	.07⅜ —	.07½
Palm, Niger	lb.	.07 —	.07½
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.12 —	.12¼
Peanut oil, refined, in bbls	lb.	.13¾ —	.14
Rapeseed oil, refined in bbls	gal.	.79 —	.80
Rapeseed oil, blown, in bbls	gal.	.86 —	.87
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.11½ —	....
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.09½ —	.09¾

FISH

Light pressed menhaden	gal.	$0.60 —	....
White bleached menhaden	gal.	.64 —	.65
Blown menhaden	gal.	.68 —	.69
Whale Oil, No. 1, crude, tanks, coast	lb.	.06 —	.06½

Miscellaneous Materials

Prices remain same as previous week

Ferro-Alloys

Quotations remain unchanged

Ores and Semi-finished Products

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

MARGERUM—The Alabama Rock Asphalt Co., Florence, Ala., recently organized with a capital of $500,000, has acquired a tract of local property, consisting of about 700 acres, with extensive asphalt deposits. Plans are under way for immediate development, to include the erection of a plant for commercial production at an early date. C. W. Ashcraft is president and general manager.

BIRMINGHAM—The Lehigh Portland Cement Co., Allentown, Pa., has awarded a contract to the Bethlehem Steel Co., Bethlehem, Pa., for the construction of its proposed cement mill on site near the city, known as Tarrant City. It will have a maximum capacity of 1,000,000 bbl. per year, and is estimated to cost more than $2,000,000, including machinery.

MONTGOMERY — The Massey Concrete Products Corp., 122 South Michigan Ave., Chicago, Ill., has tentative plans under consideration for the erection of a new branch plant on local site, estimated to cost in excess of $50,000, with equipment.

Arizona

SUPERIOR—The Magna Copper Co. is arranging a fund of about $3,500,000 for extensions and improvements in its local properties. The work will include a new smelting plant with capacity for handling about 700 tons of material per day; concentrating plant with output of approximately 600 tons; and the installation of additional machinery at its copper mines.

GLOBE—The American Ores & Asbestos Co. will discontinue operations at its plant in the Sierra Ancha Mountains, near Globe, for the mining of asbestos, and will dismantle the local furnace. It is proposed to operate in another district at a later date.

PRESCOTT—The Verde Valley Fruit & Produce Association plans for the installation of a mechanical drying plant at its proposed packing house at Cottonwood, near Prescott.

Arkansas

EL DORADO—Fire, Dec. 9, destroyed a portion of the local storage and distributing plant of the North American Oil Co., with loss estimated at $200,000, including equipment and stock. It is planned to rebuild.

California

EMERYVILLE—The Paraffine Co., Inc., has purchased property adjoining its local plant, totaling about 40 acres, and plans for the erection of additions for considerable increase in capacity. Plans will be prepared at an early date.

Georgia

HAWKINSVILLE—The Ocmulgee Brick & Tile Co. has tentative plans under consideration for extensions in its plant, to include the installation of additional equipment for brick production, and expansion for the manufacture of hollow tile. It is purposed to commence work early in the spring. J. E. and O. R. Jelks head the company.

Illinois

CHICAGO—The Evans Fibre Box Co., 4734-60 South Spaulding Ave, has filed plans for the erection of a new 1- and 2-story plant, 101x127 ft., and 21x483 ft., at location noted, estimated to cost about $150,000, including equipment.

TAYLORVILLE—The Hopper Paper Co. has taken out a state charter with capital of $350,000, to build the new paper mill on local site recently announced. The company is headed by Kenneth M. Fiske and Richard Y. Hoffman. Plans for the plant are nearing completion and bids will soon be called. It will cost $65,000.

CHICAGO—The Inlander-Steindler Paper Co., 11-13 North Green St., will erect a new 4-story building on the present site, 50x120 ft., estimated to cost in excess of $45,000.

CHICAGO—Following the recent acquisition of the John J. Crooke Co., 1649 Warren Ave., manufacturer of tinfoil, by the Midland Metal Co., same address, manufacturing tin and lead foil, plans are said to be in progress for general expansion in operations. The Crooke plant will be taken over by the Midland company and continued in service, and general improvements made. The property was secured for a consideration reported at $100,000.

Indiana

CANNELTON—The Cannelton Sewer Pipe Co., manufacturer of vitrified pipe, is taking bids for the erection of a new 4-story plant addition, to be equipped for general manufacture.

FORT WAYNE—The Fort Wayne Corrugated Paper Co., Barr and Murray Sts., has plans in progress for the erection of a 2-story addition. Bids will be called at an early date. Mills, Rhines, Bellman & Nordhoff, Toledo, O., are architects.

Kentucky

LOUISVILLE—The Pfeiffer Insecticide Co. has acquired the building at Floyd and A Sts., and plans for the installation of a new plant for the manufacture of insecticides and other chemical specialties. Equipment will be installed at an early date. F. B. Ayres, manager of the Louisville Industrial Foundation, is interested in the project.

Louisiana

LAFAYETTE — John J. Kean, formerly manager of the plant of the Lafayette Salt Co., at Anse Labutte, is organizing a new company, to be known as the Star Salt Corp., and plans for the installation and operation of a new local plant. Application for a state charter will be made in the near future.

MONROE—The Monroe-Louisiana Carbon Co. has tentative plans under consideration for the construction of a new plant at Ladel, near Monroe, to cost about $250,000, including machinery.

SWARTZ—The Atlas Oil Co. has commenced the construction of a new gasoline-extraction plant on the site of its former works, to cost about $100,000. Complete refining equipment will be installed and the previous plant capacity considerably enlarged.

MONROE—The Keystone Carbon Co. has been organized with a capital of $150,000, to construct and operate a local plant for the production of carbon black and affiliated specialties, for which plans are now well under way. The plant is estimated to cost about $75,000, with equipment, and will be of 2-unit type. C. K. Williams and J. P. Ehrhart, both of Easton, Pa., are president and vice-president, respectively, of the new company.

Maryland

BALTIMORE—The Consolidated Gas, Electric Light & Power Co., Lexington Bldg., has tentative plans under consideration for the construction of a new artificial gas plant on property recently acquired in the Turner's Station district, totaling about 50 acres. The proposed plant will cost approximately $500,000. Herbert A. Wagner is president.

BALTIMORE—The Petroleum Export Co., 638 Equitable Bldg., recently organized, is planning for the construction of a new oil-refining plant on local site, estimated to cost in excess of $300,000, including machinery. Walter B. Brooks heads the company.

EASTON—At a special election, approval was given to a plan to purchase the local artificial gas plant, to be operated in the future as municipal property. Extensions and improvements are contemplated. The local Board of Public Works is in charge.

BALTIMORE — The American Oil Co., American Bldg., has filed plans for the construction of a new storage works at Hawkins Point, to include the installation of a number of steel tanks and auxiliary operating equipment.

HAGERSTOWN—The Hagerstown Lime & Chemical Co., recently organized, is planning for the installation of a new grinding and pulverizing plant on a tract of about 40 acres of lime marl property. Bids for equipment will be asked at once. The company will operate with a capital of $30,000. J. S. Myers is president.

Massachusetts

WALTHAM—The Lockwood-Bracket Co., Boston, manufacturer of soap products, is arranging for the location of its entire plant in the building at Clematis Brook, Waltham, heretofore occupied by the Motor Specialties Co., which will soon remove its works to another location. The structure will be improved and equipment installed for soap manufacture.

Michigan

IRON MOUNTAIN—The West Chapin Mining Co., recently reorganized, has work in progress on a new blast furnace at its local properties, to have an initial capacity of 100 tons per day. Other plant extensions are contemplated. J. S. Edmundson is manager.

CALUMET—In connection with a proposed merger of the Calumet & Hecla Mining Co., with a number of its subsidiaries, including the Osceola, Centennial, Ahmeek and Allouez Mining companies, plans are being considered for extensions in the different copper properties and plants, to provide for greater output.

New Jersey

CAMDEN—Fire, Dec. 13, destroyed a portion of the plant of the John R. Evans Leather Co., with loss estimated at about $25,000, including equipment. It is planned to rebuild.

BAYONNE — The Vacuum Oil Co., 61 Broadway, New York, has awarded a contract to the Turner Construction Co., 242 Madison Ave., New York, for the erection of a 2-story storage and distributing plant at its local refinery, 75x190 ft.; work will be placed under way at once.

TRENTON — The Electric Poreclain Co., New York Ave., has filed plans for the erection of a 1-story addition to its plant.

JERSEY CITY—Graham & Zenger, 104 5th Ave., New York, manufacturers and importers of crockery and chinaware, have purchased the 2-story factory at Golden and Fremont Sts., Jersey City, totaling about 10,500 sq.ft. of floor space, for a new plant. It is planned to occupy at an early date.

New Mexico

ELIZABETHTOWN — The Ideal Mining & Milling Co. has commenced the erection of a new reduction plant at its properties, to be equipped for an output of about 50 tons per day. Considerable additional equipment will be installed at the present works, including air compressor, 200-ft. steam-operated hoist and auxiliary machinery.

New York

BUFFALO—Fire, Dec. 11, destroyed a portion of the local storage and distributing plant of the Sinclair Oil Refining Co., foot of Alabama St., with loss estimated at about $25,000. Early rebuilding is under consideration.

NEW YORK—The Pan-American Petroleum & Transport Co., 120 Broadway, has plans maturing for the development of Government oil properties in California, in accordance with agreement recently made with the Naval Department, Washington, D. C., covering Naval Reserve District No. 1. The work will include plants and equipment estimated to cost in excess of $10,000,000 for the initial operations, and more than $50,000,000 for ultimate development.

Ohio

AKRON—The Crouse Clay Products Co., manufacturer of brick, has commenced the construction of an addition to its plant, designed to increase the present capacity about 25 per cent. The machinery installation will be arranged at an early date.

CLEVELAND—The city council is considering an ordinance for a bond issue of $3,380,000, the proceeds to be used for the installation of a new filtration plant at the Baldwin reservoir. A. B. Roberts, municipal utilities director, is in charge.

CAMBRIDGE—The Universal Sanitary Mfg. Co., New Castle, Pa., manufacturer of

sanitary earthenware products, has acquired the local plant of the Florentine Pottery Co., at a bankruptcy sale, for a consideration said to be $100,000. The new owner is organizing a subsidiary company to be known as the Cambridge Pottery Co., to operate the local plant for a line of sanitary products. Improvements will be made and operations resumed shortly after the first of the year. The Universal company also has plans under consideration for extensions in its New Castle works, to double, approximately, the present capacity. C. J. Kirk is president.

ZANESVILLE — The Kerns-Korsuch Glass Co., a subsidiary of the Hazel-Atlas Glass Co., Wheeling, W. Va., has commenced the construction of a new plant of tract of 137 acres of land, lately acquired for this purpose. A large portion of the new works will be given over to the development of other hollowware products than those heretofore made. Extensions and improvements will also be carried out at the present plant. To provide funds for the expansion, the company his disposed of a bond issue of $800,000, and practically the entire amount will be so utilized.

Oklahoma

OKMULGEE—The Products Gasoline Co. has plans under way for the construction of a new gasoline extraction plant on local site. W. E. Pine is president.

CUSHING—The Home Gas Co. is planning for the erection of a new 2-unit plant for the production of gasoline from casinghead gas. It will cost about $35,000.

PONCA CITY—The Marland Refining Co. has tentative plans under consideration for enlargements in its local oil refinery.

Oregon

HUNTINGTON—The Sun Portland Cement Co., recently organized with a capital of $1,000,000, will break ground at once for a new cement-manufacturing plant, to be equipped for an initial daily output of about 1,000 bbl. of material. A power house, machine shop and other buildings will also be erected. H. A. Ross is president.

Pennsylvania

EASTON—Fire, Dec. 13, destroyed a portion of the local plant of the General Chemical Co., known as the West Easton Works, with loss approximating $22,000. It is planned to rebuild.

PHILADELPHIA — The Royal Veterinary Products Co. has leased property at 3041 Salmon St., for the establishment of a local works for the manufacture of chemical specialties. Immediate occupancy is being arranged.

PITTSBURGH—The Night Hawk Peninsular Mines, Ltd., James R. Dodworth, 323 4th Ave. (Pittsburgh-Hanover Coal Co.), chairman of the board, has plans under way for extensions and improvements in its plant and properties in the Porcupine district. A new mill will be constructed for metal reduction, with electric power plant and other mechanical buildings. To provide funds for the expansion, the company is disposing of a stock issue of $300,000.

SUSCON—Fire, Dec. 9, caused by an explosion, destroyed a number of buildings at the local plant of the Black Diamond Powder Co. It is said that the loss included one of the main mills. An official estimate of loss has not been made.

Tennessee

CHATTANOOGA—Gregg & Co., 165 Broadway, New York, engineers, have plans in progress for the construction of a new reduction plant on local site, for a company now being organized. The plant will be used for the grinding and pulverizing of non-metallic ores, including kaolin, feldspar, mica, limestone and affiliated specialties. It will have an initial production of about 50 tons per day and is estimated to cost approximately $100,000. Arrangements for equipment will be perfected soon.

Texas

PALESTINE — The Ligel Chemical Co., Houston, has acquired the lignite properties of the Anderson County Coal Co., near Palestine, and plans for the erection of a new plant for dehydrating work, including byproducts coal production. A feature will be made of the production of carbon. It is planned to commence operations at an early date.

ORANGE—The Port Vernon Oil Co. is said to be planning for the rebuilding of the portion of its local oil-refining plant, recently destroyed by fire. New equipment will be installed.

Industrial Developments

OIL—The Standard Oil Co. is increasing production at its Bayway refining plant, Elizabeth, N. J., and adding to the working force. Employment is being given to 3,000 men, or approximately the normal quota. More than 100 men have been added to the force since the first of the month.

The Haskell Oil Co. has completed a new refinery at Sigler, near Vernon, Tex., and will soon place the unit in service on a capacity basis, or about 100 bbl. of crude oil per day. This is the first oil-refining plant to locate in this district, and will be devoted to straight-run gasoline, as well as fuel oil and kerosene.

The Simms Petroleum Co. is increasing operations in the Smackover, Ark., field, and adding to its storage plant. It is proposed to develop the tankage to a maximum of 4,100,000 bbl.

The Mexico Oil Co. is planning for an early resumption of operations at its properties in the San Miguel, Mexico, district.

The National Products Co. is advancing operations at Terlton, Okla., and will soon commence the installation of a new 3-unit casinghead gasoline plant.

CEMENT—The Coplay Cement Mfg. Co., Coplay, Pa., has closed its local mill for the holidays for necessary repairs to equipment. It is proposed to resume production on Jan. 2 on a full-capacity basis.

Cement mills in the Lehigh Valley section of Pennsylvania are continuing operations at a maximum schedule. The annual shutdown periods at this time for machinery repairs will be deferred at 90 per cent of the mills, and it is not expected to curtail until plant conditions absolutely necessitate.

The Alpha Portland Cement Co. is maintaining full production at its La Salle, Ill., mill and will continue on this basis for an indefinite period. A full working force is employed. Work is in progress on additional storage at the plant, comprising a reinforced-concrete structure, 70x125 ft.

Cement mills at Birmingham, Ala., and vicinity are holding to a capacity schedule, with normal working forces. The plants are closing the best and biggest year in their history. Alabama mills have produced and sold close to 50 per cent of the 5,500,000 bbl. manufactured in the South in 1922. The largest mill in the state has shipped 1,500,000 bbl. during the last 12 months, this being the Atlas Portland Cement Co., at Leeds.

CERAMIC—About 170 potters have returned to the plant of the H. P. Wyllie China Co., Huntington, W. Va., as a result of the termination of the strike, and production at the pottery has been resumed.

The Summit China Co., Akron, O., has reopened its pottery on a full-production basis, following the return of 250 men who have been out on strike.

Lenox, Inc., Trenton, N. J., manufacturer of high-grade chinaware, has announced that the plant will be conducted as an open shop in the future. Only a portion of the men recently out on strike will be reemployed by the company.

The 10 weeks' strike in the general ware branch of the pottery industry, just closed, is estimated to have lost from 600 to 700 kilns of glost and bisque ware valued at $2,000 to $2,500 a kiln, and from 2,800 to 3,000 decorating kilns of varying valuation. The loss in wages is officially stated at $1,500,000, and with the estimated production loss, the total is $5,000,000.

IRON AND STEEL—The Alliance Steel Co. is planning for immediate operations at its new mill at Ottawa, Ill., comprising the former plant of the Central Steel Co.; it has been inactive for more than 8 years past. Production will be on a basis of 1,200 tons per month. The working force is being recruited.

The Tennessee Coal, Iron & Railroad Co., Birmingham, Ala., a subsidiary of the United States Steel Corp., is running full at its Ensley furnaces, giving 100 per cent production of pig iron.

The Witherbee, Sherman Co., New York, is making improvements at its blast furnace at Port Henry, N. Y., including the installation of a new skip hoist. It is expected to have the unit ready for blowing in late in February. Shortly thereafter, in April, the new 400-ton furnace now being built at the plant will be ready, giving a total production of 750 tons per day for the two stacks.

The Thomas Steel Co. has 6 of its 12 mills in service at the Mahoning Valley works, near Niles, O.

The Gulf States Steel Co., Birmingham, Ala., is running full at its mills, and will maintain this schedule for an indefinite period. Employment is being given to a normal working force.

The American Steel & Wire Co. has resumed operations at its mill at Anderson, Ind., following a shut-down of about 4 months. Employment will be given to approximately 400 men in the different departments.

METALS—The Butte Copper & Zinc Co., Butte, Mont., is operating on a basis of 250 tons per day, and plans to bring this output up to an average of 300 to 400 tons daily at an early date.

The Wolverine Copper Co., Calumet, Mich., is developing a production of about 900 tons per day, and purposes to increase this in the near future.

The Ray-Hercules Mines Co., Ray, Ariz., is making ready to place its new mill in service at an early date. The plant has been constructed in three units, with rated daily output of 600 tons per unit. Only one unit will be run at the present time, the others to be held ready for operation when required.

The American Zinc Co. is planning to place the new mill in service at its Silver Dike, Mont., property late in January. The plant is nearing completion, and has a rated output of 450 tons per day. The company will extend its zinc-oxide production, and has commenced improvements at its plant for this purpose.

MISCELLANEOUS—The United States Industrial Alcohol Co. will reopen its Peoria, Ill., plant at once. A full working force will be employed to develop 100 per cent capacity.

The Dunlop Tire & Rubber Corp. of America, Buffalo, N. Y., is arranging for the early reopening of its large plant on the River Road, which has been inactive for a number of months past. About 5,000 workers will be employed for initial production, and this force will be increased to 10,000 men and women at an early date.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE is holding a meeting Dec. 26 to 30 in Boston, Mass.

AMERICAN CERAMIC SOCIETY will hold its annual meeting in Pittsburgh, Pa., Feb. 12 to 17, 1923.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting April 3 to 7, 1923, at New Haven, Conn.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting May 3, 4 and 5, 1923, at the Commodore Hotel, New York City.

AMERICAN ENGINEERING COUNCIL, executive organ of the Federated American Engineering Societies, will meet in Washington, D. C., Jan. 11 and 12, 1923.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its annual meeting in New York City during the week of Feb. 19, 1923.

AMERICAN SOCIETY FOR STEEL TREATING will hold its winter sectional meeting in the City Club, Chicago, Feb. 15 and 16, 1923.

INTERNATIONAL CHAMBER OF COMMERCE will hold its second general meeting in Rome, Italy, March 19-26, 1923.

NATIONAL FOREIGN TRADE COUNCIL will hold its annual conference April 25, 26 and 27, 1923, in New Orleans, La.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS, with headquarters in Chicago, will hold its spring convention in Cincinnati, April 18, 19 and 20, 1923. The major subject will be "Management Problems of the Smaller Plants."

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, East 41st St., New York City; Jan. 5 — American Chemical Society, regular meeting. Jan. 12—Society of Chemical Industry, Perkin Medal. Feb. 9—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting. March 9—American Chemical Society, Nichols Medal. March 23—Society of Chemical Industry, regular meeting. April 20—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting. May 4—American Chemical Society, regular meeting. May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting. May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.
